CISTUS. — Bay-leaved Cistus—Sea-Purflane-leaved Cistus; also several of the other species. See CISTUS. (Shrubby.)

CITRUS, *Citron-tree*.—Lemon-tree, and Orange, with all the varieties of each. See CITRUS.

CLIFFORTIA; Ilex leaved *Cliffortia*. (Shrubby.)

CLUTIA; *Alaternoides Clutia*.—Purflane-leaved Clutia—*Elateria*, or Indian Clutia. (All shrubby.)

COLUTEA; Shrubby Æthiopian Scarlet Colutea.

CONVOLVULUS. — Ever-green Canary Convolvulus—Silvery Convolvulus. (Shrubby.)

CORONILLA. — Valentine Coronilla—Glaucous Coronilla—Silvery Coronilla. (Shrubby.)

COTYLEDON, *Navel-wort*.—Round-leaved—Long-leaved—Hemispherical-leaved. (Succulent.)

CRASSULA, *Lesser Orpine*.—Several species, see CRASSULA. (Succulent.)

CRINUM, *Asphodel Lily*.—African Asphodel Lily—Broad-leaved. (Herbaceous.)

CYCLAMEN. — Persian Cyclamen—Several varieties. See CYCLAMEN. (Herbaceous.)

DIGITALIS, *Fox Glove*.—Shrubby Canary Fox Glove.

DIOSMA, *African Spiræa*.—Opposite-leaved—Hairy leaved—Red Diosma, &c. (Shrubby.)

DRACOCEPHALUM. — Canary Dracocephalum, or Balm of Gilead. (Herbaceous and under-shrubby.)

EBONUS, *Ebony*.—Ebony of Crete. (Shrubby.)

ERYTHRINA, *Coral tree*—Herbaceous Erythrina.

EUPHORBIA, —most of the sorts. See EUPHORBIA. (Succulent.)

GENISTA, *Broom*.—Shrubby Canary Broom.

GERANIUM. All the shrubby kinds, and some herbaceous. See GERANIUM.

GNAPHALIUM. — Oriental Gnaphalium, and varieties—Sweet-scented Gnaphalium, &c. (Undershrubby.)

GREWIA. — Occidental Grewia. (Shrubby.)

HALLERIA. — African fly Honey-suckle. (Shrubby.)

HELIOTROPIMUM, *Turn-sole*.—Shrubby Peruvian Heliotropium.

HERMANIA, *Althea-leaved*.—Alder-leaved—Lavender leaved—Gooseberry-leaved. (Shrubby.)

HYPERICUM, *St. John's Wort*.—Warted-leaved Minorca St. John's Wort—Carolina St. John's Wort—China Monogynous St. John's Wort. (Shrubby.)

JASMINUM. — *Jasmine*.—Catalonian Jasmine—Azorian Jasmine—Yellow Indian Jasmine. (Shrubby.)

IBERIS, *Candy-tuft*.—Ever-green Tree-Candy-tuft; and Ever-green Striped-leaved—Ever-flowering Tree-Candy-tuft.

INULA, *Inula*. (Undershrubby.)

JUSTICIA, *Malabar-nut-tree*.

IXIA, —African Woolly-headed *Ixia*—Bulbiferous *Ixia*—Flexuose *Ixia*—Corymbose Spotted-flowered *Ixia*. (Herbaceous.)

KIGGELARIA. — African Kiggelaria. (Undershrubby.)

LANTANA, *American Viburnum*.—African *Lantana*, or *Ilex*-leaved Jasmine—Sage-leaved *Lantana*. (Shrubby.)

LAVATERA.—Cape Lavatera. (Undershrubby.)

LAVENDULA, Lavender.—Cut-leaved Canary Lavender. (Undershrubby.)

LAURUS, *Bay-tree*.—Carolina Blue-berried Bay—Red-berried Bay-tree—Indian Bay-tree—Cinnamon-tree—Camphire-tree—Deciduous Bay-tree.

LEONURUS, *Lion's-tail*.—African Scarlet Leonurus—Striped-leaved Leonurus. (Herbaceous.)

LOBELIA.—Shrubby, Pine-leaved, Blue Lobelia.

LOTUS, *Bird's foot Trefoil*.—Cretan Silvery Lotus—*Lotus Jacobæus*—Upright Lotus—Prostrate Lotus. (Undershrubby and herbaceous.)

LYCIUM, *Box-thorn*.—African Box-thorn—Barbary Box-thorn. (Shrubby.)

MALVA, *Mallow*.—African Shrub Mallow.

MEDIOLA.—Climbing African Mediola. (Undershrubby.)

MEDICAGO.—Shrubby Hoary Medicago, or Moon Trefoil.

MELIA.—Bead tree.

MENTHA, *Mint*.—Tree-Mint.

MESEMBRYANTHEMUM, *Fig-Marigold*.—Many curious species. See MESEMBRYANTHEMUM. (Succulent.)

MOREA.—Canaliculated-leaved Morea—Rush-leaved Morea.

MYRICA, *Gale*, *Sweet Willow*, or *Candleberry Myrtle*.—Oak-leaved Myrica—Æthiopian Heart-leaved Myrica. (Shrubby.)

MYRTUS, *Myrtle-tree*.—Common Myrtle; there being but one species, which comprehend many eminent varieties. See MYRTUS. (Shrubby.)

NERIUM, *Oleander*, or *Rose-bay*.—Common Oleander—with red flowers—scarlet flowers—white flowers—double flowers—striped-leaved. (Shrubby.)

OLEA, *Olive tree*.—European Olive-tree—Cape, or African Olive tree.

ONONIS, *Rest Harrow*.—Shrubby Spanish Ononis.

ORIGANUM, *Origany*.—Dittany of Crete.

Dittany of Mount Sipylus—Cretan Marjoram—Origany of Smyrna. (Undershrubby.)

ORNITHOGALUM, *Star of Bethlehem*.—Cape Onithogalum. (Herbaceous.)

OSTEOSPERMUM.—Hard-seeded Chrysanthemum. (Shrubby.)

OTHONNA, *Ragwort*.—Pectinated, or Wing-leaved Othonna—Southernwood-leaved. (Shrubby.)

PASSERINA, *Sparrow-wort*.—Shrubby African Passerina.

PERIPLOCA, *Virginian Silk*.—African hoary climbing Periploca, and varieties. (Undershrubby.)

PHLOMIS, *Jerusalem Sage*.—Yellow Phlomis, and varieties—Purple Phlomis. (Shrubby.)

PHYLICA, *Bastard Alaternus*.—Box-leaved Phylica—Heath-leaved. (Undershrubby.)

PHYLLIS, *Bastard Hare's-ear*, or *Simpla Nobla*. (Undershrubby.)

PHYSALIS, *Alkekengi*, or *Winter Cherry*—Somniferous Winter Cherry—Flexuose Winter Cherry. (Shrubby.)

PISTACIA, *Pistachia nut*, and *Mastic-tree*, two or three varieties. (Shrubby.)

POLYGALA, *Milk wort*.—Shrubby Myrtle-leaved Polygala.

PORTULACA, *Purflane*.—Shrubby Cape Purflane-tree.

POTERIUM, *Burnet*.—Shrubby Prickly Burnet.

PRASIUM, *Shrubby Hedge Nettle*.

PROTEA, *Silver-tree*.—Common Silvery Protea, or Changing-tree—Coniferous Protea. (Shrubby.)

PUNICA, *Pomegranate-tree*.—Dwarf Pomegranate.

RHAMNUS, *Buck-thorn*.—Broad-leaved Indian Rhamnus—Zizyphus, or Jojube. (Undershrubby.)

RHUS, *Sumach*.—African Hoary Sumach, and varieties—African Narrow-leaved Sumach, and varieties—Shining-leaved African Sumach. (Shrubby.)

ROYENA, *African Bladder-nut*. (Shrubby.)

RUMEX, *Dock*.—Sorrel-tree.

RUSCUS, *Knee-holly*.—Alexandrian Laurel—Tongue-upon-tongue Laurel: they will also grow in the full air, but are liable to injury from frost. (Shrubby.)

SALVIA, *Sage*.—Shrubby African Golden-flowered Sage—Shrubby African Blue-flowered Sage—Canary Sage—Mexican Sage. (Shrubby.)

SCABIOSA, *Scabious*.—Shrubby Scabious.

SCLARIA, *Clary*.—Shrubby Mexican Clary.

SELAGO.

G R E

G R E

SELAGO.—Corymbose Selago. (*Under-shrubby.*)

SEMPERVIVUM, *Live-ever*, or *House-leek*.
Tree House-leek—Variegated Tree House-leek—Lesser Canary-tree House-leek. (*Succulent.*)

SENECIO, *Groundsel*.—Shrubby African Groundsels.

SIDERITIS, *Iron-wort*.—Canary Iron-wort—Cretan Iron-wort. (*Shrubby.*)

SMILAX, *Rough Bindweed*.—Chinese Rough Bindweed, or China-root—Laurel-leaved Rough Bindweed; with several varieties of each. (*Under-shrubby.*)

SOLANUM, *Night-shade*.—*Amomum Plinii*, Bastard Capicum, or Winter Cherry—African Jagged-leaved Solanum, or *Pomum Amoris*—American Twin-fruited Solanum—Thorny, Downy Night-shade. (*Shrubby and herbaceous.*)

STOEBE.—Bastard Elichrysum. (*Under-shrubby.*)

TANAGETUM, *Tansy*.—Shrubby Æthiopian Tansy—Under-shrubby Samphire leaved Tansy—Tree Tansy.

TARCHONANTHUS.—Shrubby African Flea-bane.

TETRAGONIA.—Shrubby *Tetragonia*.

TEUCRIUM, *Germander*.—Spanish Tree Germander—Broad-leaved Tree Germander—*Polium*, or Mountain Poly.—*Murum*, or Syrian Mastich. (*Shrubby and Under-shrubby.*)

TROPÆOLUM, *Indian Cress*.—Double Indian Cress, or *Nasturtium*. (*Herbaceous.*)

VITEX, *Chaste-tree*.—Ever-green Chaste-tree.

ULEX, *Furze*, or *Whins*.—African Berry-bearing Furze. (*Shrubby.*)

XANTHOXYLUM.—Tooth-ach-tree.

XERANTHEMUM.—Broad-leaved *Xeranthemum*—Narrow-leaved *Xeranthemum*—Trailing *Xeranthemum*. (*Shrubby.*)

YUCCA, *Adam's Needle*.—Common Adam's Needle—Thready-leaved Adam's Needle—Aloe-leaved *Yucca*—Dragon tree-leaved *Yucca*. (*Shrubby-stemmed and jucculent.*)

ZYGOPHYLUM, *Bean Caper*.—Sessile-leaved Bean Caper—Purslane-leaved Bean Caper. (*Shrubby.*)

With respect to the general culture of the above list of Green-house exotics, they must be kept constantly in pots or tubs, for moving them into shelter in winter, and into the open air in summer; for being all exotics from the warm parts of the world are of ten-

der quality here, and consequently not able to live in the open air in the winter, therefore requiring the protection of the Green-house during that season, are denominated Green-house plants.

Most of them will prosper in any good rich earth of a garden; some sorts, however, require a particular compost, which will be always exhibited under each particular article; and most of the succulent tribe, as being replete with moisture, should always be planted in a dry, poor, lean, rubbishy soil. See COMPOSTS.

As to the pots and tubs to contain the plants, they must be of different sizes, according to the size and nature of the plants; which as they advance in growth, should have larger pots, &c. accordingly; and when they become too large for the pots, they must be shifted into tubs, hooped with iron, with two iron handles to each at top. See POTS and TUBS.

In planting the different sorts, be careful that the pots or tubs have holes at bottom for the discharge of redundant moisture; observing, however, previous to putting in the earth, to cover each hole with a piece of tyle or oyster-shell, to prevent their being stopped up with the earth, and the earth from being washed out, &c.

As to the mode of propagating the various sorts, it is in some by seed, others by layers, cuttings, slips, off-sets of the roots, &c. and some by grafting, inoculation, and inarching; all of which is illustrated under their several genera.

And as to the mode and times of planting each sort, it is also fully explained under their several genera as they occur in the course of this work.

Therefore, supposing all the sorts to be now raised, and planted in their proper pots, soils, &c. we will just give some hints for their general management.

Removing them into the Open Air in the Summer, and Management there.

All the sorts succeed in the open air from May, or beginning of June, until October; and from October until May or June again, as just observed, require the shelter of the Green-house: therefore, about the middle of May is the time to remove the more hardy kinds of Green-house plants, in their pots, into the full air, such as all the varieties of Myrtles, Geraniums, Oleanders, Cistuses, Phlomis, Shrubby Aster, Tree-wormwood, Tree-

Tree-Candy-tuft, Yellow Indian and Spanish Jasmines, Indian Bay, &c. and in the last week in May or first in June, according as the season proves more or less favourable, bring forth all the other sorts; but this should not be done until the season is become perfectly settled, and a fair prospect of summer being arrived, for we have often very cold nights, and frequently frosty mornings, in May, and even in the beginning of June, which, if the plants were fully exposed, would pinch the ends of their young shoots and leaves, and greatly deface them. It is a good observation, that when the mulberry-tree, which is a late shooter, begins to expand its leaves, is a certain sign of the approach of summer, and settled weather, fit to begin moving out most sorts of Green-house exotics. A mild warm day should be chosen for this work, and if a warm rain it will be of much advantage, as it will wash the leaves and branches from the dust they have contracted, and greatly refresh the plants.

When they are first brought out, it is proper to place them in some sheltered sunny place, for a fortnight, till they are inured to the open air; then you may place them in any open exposure where you design they shall remain for the summer.

As soon as they are brought out, let them be cleared from all dead leaves, and all dead wood; and let the earth on the surface of the pots be stirred, taking a little of the old out, and add some fresh mold in its stead, which will prove very beneficial; then give a moderate watering, not only to the mold, but also all over the heads of the plants, to clean them effectually from all dirt and filth they may have contracted during their residence in the Green-house.

As to the disposition of those plants in the full air, no general rule can be exhibited, it is according to fancy. Sometimes some of the handsomest plants are placed to adorn spacious fore-courts, and sometimes are arranged on each side of grand walks contiguous to the main habitation, and others near ornamental garden-buildings; they are also sometimes disposed in groups or small clumps in the most conspicuous places, in different parts of the pleasure-ground; exhibiting different sorts in each group, to cause the greater variety.

Having, however, placed the whole abroad for the summer, their chief culture is, to supply them plentifully with water during

that season, in hot dry weather: all the woody or shrubby kinds in particular, likewise the herbaceous kinds that are not very succulent, will require it three times a week at least, and in a very hot dry time once a day will be requisite; the succulent kinds must also have a moderate supply of water two or three times a week in dry weather; observing that the proper time of the day for watering all the sorts at this season, is, either in a morning before nine o'clock, or in the afternoon after four or five; for if performed in the middle of the day in summer weather, the sun would soon exhale great part of the moisture before it effected its intended operation on the fibres of the plants: this work of watering should be duly attended to in dry weather, for as the mold, roots, and fibres of the plants are circumscribed within the narrow limits of a pot or tub, the earth contained therein, as well as the fibres, consequently dries very fast in summer, and necessarily requires frequent refreshments of water, to preserve that due and constant degree of moisture requisite for the support of vegetation.

It should be observed, that moderate rains should not deter you from watering, especially such plants that have spreading heads, which prevents the rains, unless very heavy or constant, from falling in sufficient quantities on the earth of the pots, to moisten it properly.

In hot weather, if some mowings of short grass are spread on the surface of the orange-tree tubs, and others, it will greatly preserve the moisture.

During the season it will also be good culture to loosen the surface of the earth now and then, in such pots and tubs that have a tendency to bind.

Removing them into the Green-house for the Winter, and Management there.

Towards the latter end of September, or as soon as the nights become cold, begin to move into the Green-house the more tender kinds of exotics of that department; the succulent tribe in particular, should be removed to shelter at the first approach of excessive wet and cold nights. The oranges, lemons, and all the other species of *citrus*, should also be moved into shelter in due time, either in the end of September, or early in October, for if they are permitted to remain in the open air till attacked by sharp weather, it would change the beautiful verdure of their leaves,

leaves, to a rusty yellow hue, which they would not recover during winter; therefore in October at latest, begin to move in the principal plants, the succulent and others of the more tender temperature as early in the months as the cold weather begins to come on, and continue moving in all the others as the cold encreases, and by the end of the month, or first week in November, bring in the whole collection; observing according as the time approaches for moving in the different sorts, to clear them perfectly well from decayed leaves, &c. and let all the pots be well cleaned, and loosen the surface of the earth in each pot, adding a little fresh mold thereto, which will prove very beneficial to the plants, as well as add an air of neatness and culture. As you bring the different sorts occasionally into the Green-house, they may be placed promiscuously, till the whole collection is brought in, then should be arranged regular, as they are to remain for the winter; leaving all the windows quite open till that time. When the whole is brought in, or bringing in, let them be disposed in regular order, so as to appear to the best advantage, both in respect to their general arrangement, as well as to exhibit variety, and so as each may have an equal portion of sun and air: let the tallest plants be therefore arranged in the back, the others in their several ranks, according to their degrees of height, gradually down to the lowest in front; and as there is a vast variety, both in size, shape, and colour, of the foliage of the different sorts, they should be so disposed as to set off each other, and give a pleasing variety to the whole; and if possible, the plants should stand clear of one another; whereby each plant will be separately conspicuous, and the whole exhibit a greater air of freedom and variety, articles of great elegance, as well as admit an equal portion of sun and free circulation of air, which will prove beneficial to the health and beauty of the whole collection.

The plants being now all stationed in their winter quarters, their principal culture during their residence there, is the supplying them with fresh air at all opportunities in mild weather, and giving moderate waterings occasionally, picking off decayed leaves as often as they appear, and making occasional moderate fires in severe weather, also sometimes to dispel great damps and noxious fogs.

With respect to giving air, this should be admitted every mild, calm day, by opening the windows more or less, according to the

temperature of the weather. When the plants are first housed, they should have as much free air as the nature of the season will admit, by opening the windows every mild day to their full extent; and if the air is quite temperate, they may remain open on nights for the first week; but in cold nights, let them be constantly shut: this work of admitting air must be constantly attended to all winter, for without a due portion of this essential article in mild weather, the plants would lose their fine verdure, and assume a sickly yellowish colour, become diseased, and the young shoots grow mouldy and rot off, and the leaves of the plants drop; therefore, never omit every mild day, when not very damp or foggy, to open some or all of the windows, little or much, according as the air is, more or less temperate; and the proper time of day during winter, for this is from about eight, nine, or ten in a morning, till three, four, or five in the evening, according to the mildness of the day: but as the days lengthen, and the warm weather encreasing, give more air in proportion, earlier and later in the day as you shall judge proper, being careful always to shut all close in due time every evening, as soon as the sharp air approaches. In foggy weather it is advisable to keep the windows quite close, for the great damps occasioned by fogs is very pernicious to these plants, whilst they are confined in the house; likewise in all frosty weather keep the house all close, except the frost is moderate, and the middle of the day sunny and warm, when some of the windows may be opened a little, but shut them close again if the sun is clouded, and at any rate before the air changes cold; and in severe weather, let the shutters, &c. be also shut every night, also occasionally on days. As the spring approaches, and the weather grows warmer, enlarge the portion of air accordingly, admitting it also, both earlier in a morning, and continue it longer in the evening, as the days lengthen, for then the plants will begin to assume a growing state, and a considerable portion of air is requisite every mild day, both to strengthen the new shoots and inure the plants by degrees to the air, against the time for removing them into it fully again for the summer.

Watering during their abode in the Green-house will also be necessary to most of the sorts, but which must be afforded them as sparingly as possible during the winter months, and scarcely any should be given when the
house

house is obliged to be shut close through the severity of the weather: there are no certain rules to be given for the application of this article, some plants may probably require a little water once a week, or ten, or twelve days in mild weather, such as the orange and lemon-trees, myrtles, oleanders, shrubby-geraniums, and other woody kinds; all that is necessary is, just to preserve the earth very moderately moist; therefore must examine the pots and tubs always with proper attention, and give water to such only as you see are in want thereof, not to make it a rule to give it whether they want it or no. The herbaceous kinds should be rather more sparingly watered than the shrubby sorts; and all the succulent tribe should have water but seldom, some not oftener than once a fortnight or three weeks, and that always but very sparingly at each time; and some that are very succulent will require but very little from November till March; and indeed all the succulents should only have it now and then at this season, when the earth in the pots appears very dry.

In performing the work of watering in general, be particularly careful to water with great moderation whilst the plants remain in the Green-house, for if you once over-wet the earth at this season, it will remain so for a long time, and by chilling the tender fibres of the roots, the consequence will often prove the loss of the leaves of many of the plants, and even the death of some sorts.

A sunny day from about eleven to two o'clock, is the proper time for watering during their residence in the Green-house.

Let soft water if possible be used, or at least such that has been exposed to the air two or three days to soften it a little.

In frosty weather great attention is requisite to keep all the windows close, night and day, unless the frost is but moderate, as before observed, and the middle of the day sunny and warm, when some part of the house may be opened a little for two or three hours, having particular regard to shutting all close in due time in the afternoon, before the air changes sharply cold: and in very severe frosts keep all close night and day, and let the shutters, if any, or other covers of canvas or mats, be also used every night; also occasionally in day time, when the weather is intensely severe, and no sun appears, and no flues for fires to keep out the frost; observing however the shutters or other shelters besides the

glasses, must be used as little as possible in the day, only in cases of particular necessity as above, for every opportunity ought to be taken for the admission of light and fresh air, as much as the temperature of the weather will possibly admit; as most of the plants only want protection from frost, and that the common shelter of the house, with shutting the sashes close every night, will be always sufficient, except in extremely piercing weather, when the shutters, &c. must also be occasionally used; and if none, nail mats against the outside of all the glasses, especially those at top, which form a half roof, if any, for the perpendicular frosts will be more powerful in that part than in the upright glasses in front.

During severe frosty weather, if your Green-house is accommodated with flues for fires, it will be adviseable to make a moderate fire at such times when the frost cannot be otherwise kept out, especially on nights; but this must by no means be continued longer than just necessary to guard against very severe frosts. In default of flues, fires are burned within the house, in pots placed in different parts: charcoal is often used, tho' its suffocating vapours in close shut houses, is often attended with danger both to the gardener and plants, so that coal, or peat, or turf fires will be better; but there is nothing so effectual and easy as flues for making fires in severe frosts.

Likewise in very cold foggy, damp weather, a moderate fire now and then in the flues, will prove very beneficial in expelling the damp unwholesome vapours, so pernicious to all plants.

Whilst the plants remain in the Green-house, all decayed leaves, &c. should be constantly picked off, being necessary both to preserve the beauty and health of the plants; decayed leaves of the succulent kinds should be cut off close with a sharp knife; the plants in general should likewise be occasionally cleaned from any filth they may contract in the house, such as dust, cob webs, &c.

The above directions are principally all that are necessary during the continuance of the plants in the Green-house.

In May and June they are to be removed into the open air again, and managed as before directed in their summer culture.

Some Observations on their General Culture.

The plants in general will want shifting occasionally into larger pots and fresh earth, according

according as they advance in growth; some that are fast growers, such as *geraniums*, &c. will require shifting annually, others every other year, though an annual shifting will prove beneficial to most of the sorts, observing, in the work of shifting, most of them may be shifted with the ball of earth about their roots entire, others that are rather weak and sickly, will require shifting into entire fresh earth.

The proper time of year for shifting all the sorts is April and May, or when they are removed into the open air for the summer; in doing of this, the plant should be drawn out of its present pot or tub with the ball of earth about its roots entire, then pare off all the matted fibres around the outside of the ball, and clear away also some of the old earth at sides, bottom, and top: then having the new pot and fresh earth ready, cover the holes at the bottom of the pots, &c. with pieces of tyles or oyster-shells; and having then put in some of the fresh earth, place the plant in the pot and fill up the vacancy all around with more fresh compost, bringing it an inch over the top of the ball, and give directly a good watering, to settle the earth close in every part; after this it is necessary to place the plants to have shade from the mid-day sun for a fortnight.

Such plants that are become of a weak sickly nature, should, at shifting, have all the earth taken clean from about their roots, then wash the roots, and plant them into entire fresh earth.

The larger sorts of plants, such as the orange-trees, lemons, citrons, and others of large growth, should, when grown large, be shifted from pots into tubs hooped with iron, having two iron handles at top, for the convenience of lifting them in and out of the Green-house, for sometimes they grow to so large a size, having tubs in proportion, that they require two, and sometimes three or four men to move them in and out.

Plants of any of the sorts which are not shifted annually, should, in spring, have the earth in the top of the pot or tub loosened to a little depth, also a little way down round the sides, taking the loosened earth out, and in its stead, add a due quantity of fresh mould, giving it directly a little water to settle it close, which will prove a very beneficial dressing, and should never be omitted to those that are not shifted.

Likewise, at any time of the year, when you perceive the surface of the earth assume a binding property, whether in the shifted or unshifted plants, it is of much service to stir it an inch depth occasionally, and may add a little fresh compost, or none at all, as you shall judge necessary.

Keep all the sorts constantly cleared from the decayed leaves and dead wood, and their heads and every part clean from dust and other filth, by occasionally washing them with water, which in the hardy sorts is done by occasional waterings all over their heads, others when very foul, by washing their leaves one and one, with a sponge and water, especially in winter, and is often necessary to the oranges and lemons, and other large-leaved kinds.

When the heads of any of the shrubby plants are become very irregular or shabby, the branches may be pruned shorter or longer as it shall seem necessary, in April or May, and they will branch out into young wood in summer, which you may regulate as occasion may require.

Never clip the heads of any of the plants with garden shears, nor by any mode of pruning, endeavour to trim them into any regular figure, as sometimes practised, but let every sort assume its own natural growth, only just using the knife to regulate any very irregular or rambling shoot or branch, or to thin out some where too much crowded, and to cut out all dead wood.

GREWIA, (*Grewia*.)

It consists of two tender shrubs for the green-house and stove, rising five or six feet high, ornamented with oval and spear-shaped leaves, and pentapetalous flowers.

Class and order, *Gynandria Polyandria*.

Characters.] CALIX, five spear-shaped, spreading coloured leaves. COROLLA, five spear shaped petals. STAMINA, many gynandrous filaments, and roundish antheræ. PISTILLUM, a roundish, germen, filiform style, and quadrifid stigma. PERICARPIUM, a four-lobed, quadrilocular berry, and four globular seeds.

The species are;

¹GREWIA, *Occidentalis*.

Occidental Grewia.] *Grewia*, with a woody, smooth, dark-brown stem, branching eight or ten feet high, oval, acute, crenated leaves; and bright purple flowers singly from the sides of the young branches.

²GREWIA, *Orientalis*.

Oriental Grewia.] Grewia, with a woody brown stem branching out laterally five or six feet high; oval, spear-shaped, serrated, alternate leaves, and greenish flowers in clusters from the sides and ends of the branches.

These shrubs flower in summer, but are not succeeded by ripe berries in England.

They are propagated by seed, layers, and cuttings; sow the seed in pots, and plunge them in a hot-bed; layers may be performed in spring, and they will be rooted by the end of summer; and cuttings may be planted in pots also in spring, plunging them in a hot-bed; they will be rooted in two or three months.

GROVES, plantations of stately trees disposed in rows on grass-ground in gardens, and parks, contiguous to spacious lawns, &c. designed both for ornament, and to form shade from the summer's sun.

In extensive gardens Groves may be formed in different parts of the ground; a grand one contiguous to the dwelling, where it may be conspicuous, is proper, both to effect ornament, and that company may soon arrive under its shade for occasional walking in the heat of summer; others may be stationed more remote from the habitation on the boundaries of lawns or other open spaces of grass, and near garden buildings, such as temples and other sacred structures; for Groves wheresoever situated, always exhibit an air of magnificence, and are the greatest ornaments to spacious gardens, and every such garden is incomplete without one or more of these plantations.

The trees to form Groves are usually disposed in several straight rows, and at such distances as their branches may so far approach each other, as to afford a moderate shade from the summer's sun, yet so distant, that each tree may have full scope to spread its branches all around, so as to exhibit their straight trunks and spreading heads distinct, according to their natural growth; that a due portion of air and light may be admitted to promote the growth of the grass between and under them, so as to form a close, firm sward, and perpetual verdure; Groves are also sometimes formed with the trees placed irregularly, and the spaces between planted with various shrubs to form under-wood, and with serpentine gravel walks variously winding through the whole.

But Groves are of two sorts, open Groves, and close Groves.

Open Groves.—The largest growing forest-trees with the most spreading heads, should be chosen for such plantations, and disposed in ranges from fifteen to twenty or thirty feet wide, and the same distance between the trees in each row, that each tree, as above observed, may have full scope to form a spreading head, and so as to admit of the growth of grass under them sufficiently to form a good sward, and constant verdure; but if a shady Grove is required to be formed as soon as possible, one may be planted contiguous and distinct from the above, arranging the rows only at ten or fifteen feet distance, whereby it will afford shade several years before the other, and as it will always exhibit a more dark and gloomy shade for solitude, it will exhibit the greater variety, with the other more open Grove. Open Groves chiefly for shade are also formed by disposing all the trees irregularly, both that they may produce an imitation of a natural Grove, and sooner afford a perfect shade and gloominess, which they will considerably sooner than in straight rows, though Groves designed principally for ornament, having the trees disposed in wide ranges, appear generally with a greater air of grandeur as open Groves; but where there is extent of ground to work upon, open Groves may be formed in all the above methods.

Close Groves.—These are formed of large trees irregularly disposed, having the ground between them filled with various under shrubs and gravel or sand walks, continued through them in winding or serpentine turns; and which kind of Groves are sometimes continued round the out boundaries of a garden, so as to afford shady and private walking, as well as shelter from the inclemency of cold cutting winds; and the various shrubs forming the under-wood will have a delightful effect in the whole excursion of the walk.

But with respect to Groves in general, it sometimes happens when a garden is to be laid out, that large old trees are found growing upon the spot, in a proper situation to constitute a Grove, which if they do not too greatly approach to the habitation, nor obstruct any principal prospect or distant view, they should be preserved with the utmost care; and at any rate it will be better to dispense with many inconveniencies, than to destroy them, which would require an age or

two to form the like with any young plantation; and that although the trees should stand ever so irregularly or close, they may be somewhat regulated by grubbing up the most irre-

gular and ill formed, or thinning out some, where they form too close a thicket for the design, either for an open or close Grove.

H.

HÆMANTHUS, Blood-flower.

The plants are bulbous-rooted, herbaceous, flowery perennials for the stove, having the roots crowned with long leaves, and erect flower-stalks a foot high, terminated by clusters of monopetalous, six-parted, liliaceous-shaped red flowers.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, a large six-leaved, permanent involucre, shaped like an umbel. COROLLA, is one erect petal, divided into six parts. STAMINA, six awl-shaped filaments, and oblong incumbent antheræ. PISTILLUM, a germen under the corolla, single style, and stigma. PERICARPIUM, a roundish trilocular-berry, and three seeds.

The species;

¹HÆMANTHUS, *Coccineus*.

Scarlet Cape Hæmanthus, or Bloody Lily.]

Hæmanthus with a large, tunicated, bulbous root; crowned by tongue-shaped, flat, smooth, fleshy leaves, spreading on the ground, and an upright, thick, spotted stalk, from three to ten or twelve inches high, terminated by a large cluster of blood-red flowers in autumn.

²HÆMANTHUS, *Puniceus*.

Red Guinea Hæmanthus, or Bastard Dragon.]

Hæmanthus with a large, bulb-like, fleshy root, sending up thick, fleshy stalks a foot high, spotted like the dragon-plant, and garnished with lanceolate-oval waved, erect leaves, and large umbellate clusters of red flowers in summer.

³HÆMANTHUS, *Carinatus*.

Carinated-leaved Cape Hæmanthus.] Hæmanthus with a large, bulbous root, crowned by three or four long, narrow, carinated, or keel-shaped leaves; an upright, thick stalk a foot high, terminated by a cluster of pale-red flowers in autumn.

⁴HÆMANTHUS, *Ciliaris*.

Ciliated Cape Hæmanthus.] Hæmanthus

with a large, bulbous root, tongue-shaped, ciliated leaves, and an upright, thick stalk a foot and half high, terminated by reddish flowers in autumn.

All these plants are exotics of Africa, and require the protection of a hot-house in this country, so must be always kept in pots, and continued in that department, where if plunged in the bark-bed, they will flower annually, and make a fine appearance.

They are herbaceous, bulbous-rooted perennials, durable in root, but renew their leaves and stalks annually, observing, that the autumnal flowering kinds generally flower before the leaves arise; and when the flower fades, the leaves come up, continue all winter, and decay in spring or early in summer.

Their flowers are extremely ornamental, appearing in large clusters, protruded from a large permanent involucre; each separate flower is of one petal, divided into six parts; see the *Characters*, and are succeeded by red berries, but rarely any but the second sort ripen in perfection in England.

All the sorts must be potted in light earth, and the proper time for planting, transplanting, or to new-pot them is in spring, or early in summer, when their leaves decay, and the roots may be had of most of the nursery-men, who propagate them for sale; tho' they encrease but slowly here, so are often procured from the Cape of Good Hope, where they naturally grow, they should be planted as soon as they arrive, observing to supply them with water, which however must be but sparingly in winter.

They may be propagated by off-sets from

the roots, when their leaves, &c. decay, like bulbs; and may also be propagated by seeds sowed in pots of light sandy earth, plunging them in the bark bed in the stove.

HÆMATOXYLUM, Blood-wood, or Log-wood.

It furnishes one species, an exotic-tree of South America retained here in stoves for variety.

Class and order, *Decandria Monogynia*.

Characters.] **CALIX**, is five-parted, and permanent. **COROLLA**, five oval petals. **STAMINA**, ten long filaments, and small antheræ. **PISTILLUM**, an oval germen, simple style, and thick indented stigma. **PERICARPIUM**, an unilocular capsule and compressed seeds.

There is but one species, viz.

HÆMATOXYLUM, *Campechianum*.

Campeachy Hæmatoxylum, or Log-wood.] Hath an irregular, crooked stem, rising fifteen or twenty feet high, sends out many crooked branches armed with thorns, and garnished with pinnated leaves of three or four pair of lobes; and from the axillas erect bunches of pale yellow flowers, succeeded by oblong capsules containing the seeds, but do not produce any in this country.

The wood of this tree is in great estimation among the dyers, for dying purple and the finest blacks, and grows in amazing plenty in the Bay of Campeachy, and other parts of the Spanish West Indies, from whence the wood is sent to Europe as a valuable commodity, and is become a considerable branch of trade.

A few of the plants are preserved here in hot-houses for variety, where they grow freely, and attain several feet in height.

It may be propagated by seeds procured from abroad, sowing them in pots, and plunge them in a bark hot-bed: when the plants are three inches high, prick them in separate small pots, and replunge them in the bark-bed in the stove.

HALLERIA, African-fly Honey-suckle.

One species, an ever-green shrubby plant for the green-house, constitute this genus.

Class and order, *Didynamia Angiospermia*.

Characters.] **CALIX** is monophyllous, three-parted, and permanent. **COROLLA** one ringent, or grining petal, having the limb erect and four-parted at the top; the upper part longest, blunt, and emarginated; the side ones short and pointed; and the lower one very short and acute. **STAMINA**, two

long and two short filaments, and didymous antheræ. **PISTILLUM**, an oval germen, long style, and simple stigma. **PERICARPIUM**, a roundish bilocular berry, and two hard seeds.

The species is;

HALLERIA *Lucida*.

Lucid or Shining-leaved Halleria.] **Halleria**, with a woody stem, branching six or seven feet high; oval, sawed, shining green leaves placed opposite; and red flowers growing scatteringly along the sides of the branches in June, succeeded by roundish berries in autumn.

This is an ever-green shrubby plant of Africa, requiring shelter of a green-house here in winter, and must be always kept in pots, and managed as other exotics of the green-house department, and will make a pretty variety in that collection.

The flowers are of the grining tribe, being formed of one irregular-petal cut into four unequal segments, and resemble some sorts of honey-suckles. See the *Characters*.

It may be raised from seed, in a hot-bed in spring; also by cuttings of its young branches, planted in pots in April, May, or June, and plunged in a hot-bed, giving occasional shade and water.

HAMAMELIS, Witch Hazel.

It furnishes one hardy deciduous shrub for the shrubbery.

Class and order, *Tetrandria Digynia*.

Characters.] **CALIX**, a triphyllous involucre, and a double proper cup, or perianthium, having the exterior part of two, and the interior part of four leaves. **COROLLA**, four long narrow reflexed petals, and four nectariums adhering thereto. **STAMINA**, four narrow filaments, and horned, reflexed antheræ. **PISTILLUM**, an oval hairy germen, two styles, and capitated stigmas. **PERICARPIUM**, none. **SEMINA**, an oval nut situated in the calix.

The species is;

HAMAMELIS *Virginiana*.

Virginian Hamamelis.] Hath a shrubby or woody stem, branching three or four feet high; oval, indented, alternate leaves, resembling those of the common hazel, and flowers growing in clusters from the joints of the young branches; appearing at the fall of the leaf in November and December, but producing no seeds in England.

This is an American shrub, of hardy growth; is admitted here in our shrubberies

to increase the variety in the collection of hardy shrubs in extensive gardens; but its flowers are more singular for their appearance in winter, when the leaves are fallen, than their beauty.

It is propagated by seed, and by layers of its young branches.

By Seed.—This is procured from America; sow it in an easterly border, half an inch deep, they will come up the second spring, not before, so keep the ground clean from weeds till then; when, if the season proves very dry, give moderate waterings, also in summer; and when two years old, transplant them in nursery rows.

By Layers.—In autumn, or even in winter, and early in spring it may be done, and the young twigs of the last summer's shoot should be chosen, giving them a slit at a joint, lay them in the earth, and they will be rooted, and fit to transplant into the nursery by autumn following.

HEDERA, Ivy, the Ivy-tree.

This Genus furnishes two shrubby climbers, one an ever-green, the other a deciduous plant, both celebrated for their climbing property, in ascending to the top of the highest trees, buildings, or any adjacent support, rooting in the bark of the trees, walls, &c. as they ascend.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, a small many-parted involucre to each corymbus of flowers, and a five-parted cup to each floret. COROLLA, each floret composed of five oblong spreading, incurved-pointed petals. STAMINA, five awl-shaped filaments, and incumbent Antheræ. PISTILLUM, a turbinate germen, short style, and single stigma. PERICARPIUM, a globular unilocular berry, and five seeds.

The species are;

¹HEDERA, *Helix*.

Helix, or *Common Evergreen Ivy-tree*.] Hath shrubby, long, flexible, rooting stalks, climbing upon support many feet high, by their cirrhone roots emitted from the sides of the stalks and branches, striking root in the bark of trees, walls, &c. as they ascend; garnished with large lobated, and sometimes oval leaves, and corymbose clusters of greenish flowers at the ends of the young shoots, succeeded by round clusters of berries ripening to a black, and a yellow colour in the varieties.

Varieties of this are;] Common black-berried ivy-tree—Silver-striped-leaved ivy—Gold striped ivy—Yellow-berried ivy.

All these varieties are ever-green; they flower in September, and the berries continue their growth all winter, and ripen towards spring, which in contrast with the leaves exhibit a delightful variety; but the yellow-berried kind is rare in this country.

²HEDERA, *Quinquefolia*.

Five-leaved deciduous Hedera, commonly called *Virginia Creeper*.] Hath shrubby very long slender rooting stalks, climbing upon support an hundred feet high or more, by their cirrhone-roots from the sides of the stalks, striking root in walls, &c. as they ascend; garnished with quinquefoliate deciduous leaves, being composed of five oval serrated lobes, closely covering all the stalks and branches in summer, dying away to a reddish tinge in autumn.

Both the above species are shrubby and durable in stem and branches; the first and varieties are ever-green; the second is deciduous, dropping its leaves in autumn; are both exceedingly hardy, prosper almost any where, and are remarkable for their singular property of emitting rooting cirrhi all along the sides of their stalks and branches, striking root in any neighbouring support, thereby climbing to a prodigious height.

The first species, *Hedera Helix*, or common Ivy, is well known to all, by its growing wild in our woods, hedges, and upon old walls and other buildings, &c. especially the common green sort, which by its climbing stalks and branches rooting all along in the bark of the adjacent trees, &c. ascends and surrounds their stems, and mount to their tops; also over-runs walls, pales, and the whole sides and tops of houses, rearing its head often above the chimney, and frequently ascends to the very top of church-towers in the country; closely attaching itself to its support by its cirrhone-roots emitted from all the stalks and shoots in their progress of climbing; and having reached the top of its support, of whatsoever kind, it there forms a short woody trunk, and large bushy head. In default of support, it will run upon the ground, branching and rooting as it advances, and soon cover a large space; therefore, with respect to its use in gardening, it may be planted to cover the surface of unsightly walls, old pales, and the like; which it will soon effect with little trouble; it is also excellently

ly adapted to over-run grottos, caves, cots, hermitages, root houses, artificial ruins, &c. to give them a more rural appearance; likewise may be planted here and there in wildernesses, close groves, shady walks, and other places of solitude, to run up large trees; and for variety may station a plant here and there in open shrubberies, placing a stout stake or post for it to climb upon, which it will soon surround and hide, and rear its head above it, and form a thick bush at top; it may also be trained up to a stem, and made to form a bushy head. Thus may the Ivy-tree, though a common wild plant, be employed in our gardens, but its commonness rendering it of little estimation with most, it is seldom cultivated: all the varieties, however, are beautiful ever green climbers; the striped-leaved kinds in particular have singular elegance, when trained against walls in any conspicuous situation; and all the sorts may be raised abundantly by cuttings of their shoots, which root freely, make amazing progress in growth, and fasten themselves to any support with very little assistance.

The second species, *Hedera Quinquifolia*, is an American plant, but so hardy that it will prosper any where, and is a true species of the Ivy, as it climbs and plants its roots into walls, &c. like that plant; is of surprising quick growth, frequently shooting twenty feet or more in one summer, striking root into the joints of walls, mounts to the top of the highest buildings, branching and spreading widely each way; and as it prospers in any situation, is well calculated to plant against any unsightly walls or high buildings, to cover them, and for which purpose it is greatly used in London, no plant being so well adapted, as it will thrive in the midst of that city, amongst the closest buildings, and soon reach their tops, covering them effectually with its beautiful five-lobed foliage in summer.

Propagation.

Both the species and respective varieties are propagated with great facility, by cuttings of their young shoots in autumn or spring in a shady border, which will readily take root, and in one year will form good plants, and may then be planted out for good where they are to remain, or remain longer in the nursery, as may be convenient; cuttings may also be planted at once where they are to remain, and they will also succeed: the common Ivy may also be propagated by seeds, sowed as

soon as they are ripe, in March or April, which, if kept shady and moist, will often rise the same season.

When any of the sorts are planted against walls, &c. they will only require a little conducting at first, just to nail their first shoots thereto, they will afterwards plant their roots firmly in the support, and fix themselves.

HEDGES, growing fences, employed occasionally both for use and ornament, as outward fences to gardens, and to divide the internal parts of the ground.

Growing Hedge-fences are the cheapest, the most eligible, and ornamental garden-fences that can be employed in such parts where walls, &c. are not particularly necessary for wall-trees, and may in such cases be employed, both as outward fences to garden-ground, nurseries, and plantations; as also to divide, where necessary, the different parts of the ground; in both cases serving as a defence against men and beasts, as well as afford occasional shelter and shade to particulars, as effectually as the best wall or paling fences.

Several sorts of shrub and tree-plants, both deciduous and ever-greens, may be occasionally employed for hedges, either as outward fences, and for dividing any internal portion of ground.

For outward Hedges.

The white-thorn or haw-thorn-tree, forms the best outward hedge-fence in the world; which being properly trained by trimming, or clipping annually, is rendered the closest and hardiest fence of any other tree yet known; and being very durable, is preferable to all others for outward Hedge-fences both to gardens and fields; also for the divisions of fields, where they are exposed to cattle; and for either purpose a hedge of this sort is formed by planting young plants or sets raised from seed in the nursery, which when a year or two old, or as big as a goose-quill, are of a proper size for this use; and the methods of planting them is exhibited hereafter; and for particulars in raising the plants, see *CRATÆGUS*.

Hedges of this plant are commonly called quick-set Hedges, in a customary or confined sense, though in a general sense it may with propriety be understood of all growing Hedges, to distinguish them from dead-hedges, formed with stakes and bushes.

The black-thorn, or floe-tree, is also proper

per to be employed for field Hedges, and forms a very strong durable fence; but by its producing such abundance of suckers from the root, widely on every side, as to over-run the adjoining ground, renders it the less esteemed for general use; as it is however well armed with thorns, it may be rendered a very good outward fence against most cattle, or to divide fields, &c. and a Hedge of this tree may be raised either by sowing the seed, i. e. the sloes themselves, in autumn as soon as ripe, in the place where you would form the Hedge, in two drills the whole length, a foot asunder, and an inch or two deep, covering them over with earth; or you may first raise the plants in a nursery, or procure young setts from the neighbouring hedges, as this plant never fails affording great abundance of suckers or spawn, which they send up annually from its roots; so that having procured of either sort, plant them in one or two rows the whole length of your intended Hedge. See PRUNUS.

The crab-tree, both of the apple and thorny sorts of plums, are also sometimes planted for Hedges, and will soon grow up; observing that plants for this purpose should be such as are raised from the kernels of the true wild crabs, which generally come more thorny than those of the cultivated kinds, and shoot more moderate and close, so as to be more readily kept within the proper limits of a Hedge; and a Hedge of them may either be raised by sowing the kernels of the fruit in autumn or winter, in the place where the Hedge is intended, in drills the whole length an inch deep, covering them that depth; or may raise plants from seed in the nursery, which when a year or two old, plant out for good. See PYRUS and PRUNUS. A Hedge of these plants is only recommended as being of quick growth, and in default of better; and besides its property as a field-fence, some plants of the Hedge may be suffered to grow up, and they will afford an annual crop of crabs for verjuice; and a proper number of the plants may be used as they stand in the Hedge for stocks, to graft either with useful family apples, or sorts proper for cyder.

The elder-tree is also frequently used for outward Hedges, especially when a fence is wanted as soon as possible, as it will form the most expeditious Hedge-fence of almost any tree in the world, though not the most effectual nor beautiful; however, where an immediate outward Hedge-fence is required to

any out-ground, or plantation, the elder may be made to form a good one in one year, by planting large truncheons, or cuttings of the straightest upright shoots and branches, from two or three, to six feet long, planted either upright a foot distance, and wattled along the top to preserve them firm and even; or may be placed slanting across one another chequer-wise, forming a sort of lattice-work, which will be the most effectual method. In either method of planting, sharpen the lower ends of the cuttings, making holes to receive them fifteen or eighteen inches deep, either in level ground, or the sides or tops of banks; they will ready emit roots, and shoot strongly at top the same year; but for their general propagation, see SAMBUCUS.

The alder-tree is also proper to plant for Hedges in wet or marshy ground, as being an aquatic, and will grow by small or large cuttings like the elder, and will soon form a fence; and where Hedges are necessary by the sides of rivers, brooks, or other water, this tree is very proper; as its roots and numerous suckers arising from their lower parts, form such a close thicket, as effectually to preserve the earth of the banks from being undermined and washed away. See BETULA ALNUS.

Holly forms an excellent and most beautiful hedge, and is the best ever green Hedge that can be planted for an outer Hedge-fence; for it grows very close, and is well furnished with leaves, which being armed with thorns, no cattle will brouze upon them; and being always in foliage, affords good shelter in winter, and appears ornamental at all seasons. The only objection to a holly Hedge for general use, is its slowness of growth the first four or five years, as rooting but moderately; but when once it has established itself, it makes amends by its progress in height, strength and thickness; and, as a fence, is equal, if not superior to any other Hedge whatever; and for beauty, may be said to surpass all, if neatly trained by clipping once or twice annually in summer. A Hedge of this sort is formed either by sowing the seeds at once in the place where you intend to have the hedge, in drills an inch and half deep; or by planting young plants of two or three years old from the nursery, which is rather the most eligible practice, planting them in one or two rows, tho' two rows planted a foot asunder, and the same in each row, will form the thickest hedge; but either of which will
in.

in eight, nine, or ten years form a good fence. For particulars in raising the plants, see ILEX.

The furze plant is sometimes used for an outward ever green Hedge fence for fields, which, however, makes but an indifferent hedge, being apt to die off in gaps; but as it will grow upon dry banks, or any poor dry soil, where scarcely any other plant will thrive; it may on that consideration be used for a hedge; which is to be effected by sowing the seeds in autumn, at once in the place where it is designed to have the Hedge, in drills an inch and a half deep. See ULEX.

With respect to the method of planting the above kinds of Hedges, take the following hints:

All outward Hedges designed as fences, should have a ditch and bank; the ditch to be on the outside, three or four feet wide at top, three deep, sloping to one wide at bottom, raising a low bank on the inside on which to plant the Hedge, which may be planted either on the side of the said inner bank, in two rows one above the other, a foot asunder, as commonly practised for quick Hedges, planting them as you advance in forming the ditch and bank; or may be planted entirely on the top of the bank, first forming the ditch and bank, and levelling the top of the bank, so as to form a sort of border; then plant the sets in one or two rows, the whole length; but two rows a foot asunder, is the most eligible for all outward fences, as it always forms the thickest, strongest, and most effectual Hedge-fence; but the particular method is exhibited below.

As the haw-thorn or white-thorn Hedges, commonly called quick, or quick-set Hedges, are the most effectual and most frequently used outward Hedge-fence, we will therefore first exhibit the method of planting and forming these kind of Hedges as outer fences against cattle, &c. which to render it more effectual, should always have a ditch and bank as above observed; the plants or sets for forming the Hedge, are raised from the seed or haws, as directed under their proper genus. See CRÆTÆGUS *Oxyacantha*; and when from one to two or three years old, about the size of a goose-quill, or a little more or less, are proper sets for planting out to form Hedges, as observed in their propagation. Having your quick ready, then in the place where you intend to plant the Hedge, mark out a space for a ditch,

three or four feet wide at top, as before observed; which is to be digged three feet deep each side, sloping gradually to a foot wide at bottom, forming a bank along upon the inner edge, on which to bed or plant the quick, which should be planted as you advance in forming the ditch and bank; therefore, having lined out the width of the ditch, then along the inner edge lay a row of square spit-turfs grass-side downwards, to form the beginning of the bank, backing it up with spits of earth from the formation of the ditch, and top it with a little of the fine mold or crumbs, and then upon this proceed to lay the first row of quick: first let the sets be headed to about five or six inches, and the roots trimmed, then lay them upon the bed of turf, with their top-ends outward, in an upward direction, about ten or twelve inches asunder; covering their roots with mould also out of the ditch, and then lay another row of turf along upon the necks of the plants, and more mould from the ditch upon, and behind the turf; and when the bank is thus raised a foot above the row of sets, plant another row in the same manner, placing each set against the spaces of those of the first row, so covering them with more earth from the ditch, forming it in a flat bed over the sets, four or five inches deep; continuing the ditch to the depth of three feet, sloping each side, to one foot width at bottom, and trim up all remaining earth, throwing a sufficiency behind the top of the banking, to back up the whole even, in a sort of broad border, all the way along the top, sloping a little back so as to correspond nearly with the adjoining ground.

But in planting the above kind of Hedge, or any other sort, for an outward fence, &c. some form the ditch and bank first, as above, and plant the sets in two rows along the top; that is, after having formed the ditch and bank, then levelling the top, forming a sort of border all along a yard wide; plant the sets along the middle thereof upright, in two rows a foot asunder, and six inches distant in each row; the mode of planting to be as hereafter directed; observing the same when intended to raise a Hedge at once from seed, sowed where you design the Hedge to be, sowing them along the top in drills a foot asunder.

Sometimes when Hedges are designed for middle fences to divide fields, a two-sided bank is raised a yard high, and as broad at top, having a slight ditch on each side; and each

each side of the bank is formed with square spit-turfs, from the adjoining ground, and the middle filled up with mold from the ditches on each side; so that, when finished, it forms a yard-wide border all the way along the top; and along the middle of which plant two rows of Hedge-fets, or seed, in drills as before observed.

But in places where no ditch, nor raised bank is required, as may be the case for middle Hedges, in the more interior parts of grounds, especially in gardens; then the place for the Hedge being marked out on the level ground, two or three feet broad, dig it along, one good spade deep at least; and then plant your sets of any sort in two rows, ranging along the middle, as hereafter directed; or, if you design to sow seeds, &c. of any sort at once, where you intend to have the Hedge, sow them in two drills, a foot asunder, the whole length.

Having given directions above for the method of planting the sets of quick upon the side of a ditch and bank, the following hints are of the particular manner of planting any sorts upon level ground.

With respect, therefore, to the particular mode of planting the sets, or plants of any sort, for a Hedge upon level ground, either on the top of a bank levelled, or entirely upon the general level surface, where no bank is necessary, as for middle Hedges in gardens, &c. the following methods are practised.— That having, in the place where the Hedge is intended, either upon the top of a bank, or general level, formed a sort of level border, two or three feet wide the whole length, you may form one or two slight narrow trenches, along the middle, for the reception of the sets; that is, either cut out a narrow trench, six or eight inches deep, all the way along, for each row of sets, making one side of each trench upright, as practised in planting box-edgeings, see *BUXUS*; then place the sets in the trench against the upright side, eight or ten inches asunder, and turn the earth in upon their roots as you go on, and tread it close thereto; and then, if you design to plant two rows to form a double Hedge, make another trench a foot from the first, and plant it in the same manner; or, instead of the above method of planting the sets, they may be trenched in by digging a foot-wide trench all the way along, placing the sets therein as you go on, in the following manner: with your spade chop out, or mark out a trench a

foot wide; then, having the plants, begin at one end, dig out a spit the width of the trench, and then plant one or two sets close to the sides of the trench: but if intended to have a double Hedge, place two sets so as to form two rows; then dig another spit, and turn the earth upon their roots; then place two more sets in the same manner, at eight or ten inches distance from the first two, and turning another spit of earth upon them; after these two more at the same distance; and in this manner proceed digging along, and planting the sets as you advance, till the whole is finished.

In respect to the training and general culture of these sorts of Hedges, it must be remarked, that all such that are exposed to cattle, must, as soon as planted, be fenced either with a stake and bush Hedge, with hurdles, or with rails and open paling, four or five years till the hedge grows up; observing not to place the fence too close to the Hedge to interrupt its growth. The Hedge must also be duly weeded while young, and this should be particularly attended to the first two years.

And if designed to train the Hedge regular by clipping it with garden shears, it should be annually performed in summer, observing however to top it but sparingly while it is young, until arrived at its intended height, only just trim off the tops of the straggling shoots to preserve a little regularity, and promote lateral wood to thicken it as it advances; and cut it in also moderately on the sides; but when arrived at nearly its proper height of four, five, or six feet or more, then trim it close on the sides and top, annually to preserve it thick and within its proper bounds, cutting the sides always first as even as possible; then the top, which should also be cut as even as a line, always cutting in nearly to the old wood of the former year's cut, otherwise your Hedge will get too broad, and keep always the top narrower than the bottom.

But as to field Hedges, which are rarely clipped, they grow naked or open at bottom, and will want plashing or laying every seven, eight, or ten years, to preserve them thick at bottom, to answer the purpose of a fence. See *PLASHING HEDGES*.

Internal Hedges, both as Fences and for Ornament.

Having mentioned above the various sorts of plants proper to be employed for outward Hedges,

Hedges, either for gardens or fields, for the purpose of strong fences, we now proceed to point out the sorts for internal or middle Hedges in gardens, either as fences or to form shelter, and for ornament.

In former designs for gardens, regular Hedges were in great request; almost all the different compartments and divisions of pleasure-grounds were surrounded with Hedges formed of various sorts of trees and shrubs, both ever-greens and deciduous kinds, which being neatly trained and clipped once or twice annually, appeared sometimes very ornamental in themselves; but as they shut out from view, the various plants and trees growing in the quarters, which were infinitely more agreeable, as garden furniture, than the perpetual shew of so much Hedge-work obtruding always upon the sight, they are now almost totally excluded our gardens, for they at one time so greatly prevailed by way of ornament, that they bounded all the walks, that wheresoever one walked, close Hedges presented themselves ever in view on both sides of the walk, six or eight feet high, shutting out all other objects from sight, that it was like walking in a lane between two walls; and the beauty of the internal plantations were lost to persons in the walks. The error of so many surrounding Hedges were so evident to persons of taste, besides their stiff formal appearance, and expensiveness to keep in order, that they were banished from most gardens; and in modern designs, consulting prospect and rural disposition in imitation of nature, nothing of Hedge-work is admitted, except merely as fences, or for shelter, or to hide any disagreeable object; however, for the sake of variety some Hedge work for ornament might still be introduced in large gardens, in contrast with rural designs, as a little of regular and a little of rural performances in different parts of the garden, will diversify the general scene; observing, however, Hedges should be but sparingly admitted, and never to bound walks, nor surround entirely any compartments furnished with curious trees or plants, except by way of fence, or for shelter, or shade where necessary.

Tall Hedges of elm, beech, lime, and other deciduous trees, trained forty or fifty feet high or more, were in great repute at one time for ornament, and sometimes were so stationed as to exhibit an air of grandeur; but their great height rendering them very

expensive, and troublesome to clip, they are mostly discontinued.

Hedges in ancient designs were also formed into various devices of rural architecture, pavilions, cabinets, porticoes, galleries, and other regular performances, which greatly prevailed, and were often trained so as to exhibit an air of magnificence as garden furniture; but were as often so ill formed, according to the design they represented, that they were offensive to sight, and were rooted out of many gardens, though something of this nature might be introduced with moderation for variety.

As several different sorts of trees and shrubs, both ever-greens and deciduous plants, are employed in forming garden Hedges, the principal of them are exhibited below, under the heads, Ever-green Kinds, and Deciduous Kinds.

Ever-green Kinds.

The principal ever-greens employed for Hedges are:—Holly—Yew—Laurel—Laurustinus—Phillyrea—Alaternus—Bay—and Ever-green Oak; all of which will form Hedges from five or six, to ten or twelve feet high; and the last named sort, Ever-green Oak, may be lead up to twenty feet: but the holly and yew form considerably the best Hedges for general use. Besides the above seven sorts for tall Hedges, sometimes also are used for lower Hedges:—Ever-green Privet—Tree Box—Juniper—Virginia Cedar—Savin—Rosemary—Pyracantha—and Sea Purslane Shrub, and some other ever-greens of similar growth.

Of the above list of ever-greens for Hedges, the holly and yew form the closest and most effectual garden-hedges of any of the sorts, as they will grow so thick and close, that a bird can hardly get into them, and may be trained ten or twelve feet high, or more; tho' from about six to eight or nine feet, is the most eligible height for these kinds of Hedges for general use: both the sorts may be easily trained to almost any form by an annual clipping, more particularly the yew; but the holly makes rather the most eligible Hedge as a fence, and also for ornament; but is singularly beautiful when the common green sorts and the variegated kinds are alternately intermixed. The yew, however, as producing the most numerous closely-placed small shoots, thickly set with very small leaves, grows

grows the closest, and is the most easily trained into any desired shape, of any Hedge in being, as is evident in some old gardens, where many of these hedges are still retained, exhibiting the remains of the ancient taste of design in gardens; in which some are trained into common regular Hedges, and some have the hedge-work formed into various shapes and figures; as arcades, niches, cornices, porticoes, pilasters, galleries, figures of men, beasts, and birds, and many other formal works of art. The yew is also a very proper Hedge to plant internally in nursery grounds for shelter to young plants.

To form internal or middle Hedges of these two sorts, plant them in one row, which is sufficient, along the place where the Hedge is intended; placing the holly at about a foot or a foot and a half distance, and the yew the same, but if spreading plants, two or three feet.

The laurel being a singularly beautiful ever-green, adorned with noble large foliage, is sometimes planted for Hedges; but as it shoots vigorously, it never grows so compact, nor is so easily kept in form as the two fore-mentioned sorts; its leaves also being very large, when the hedge is clipped with shears, they are unavoidably cut through, and so stubbed and mangled as to have a very disagreeable appearance; therefore, instead of performing their annual training with shears, some trim off the shoots with a knife, to preserve the leaves entire. This plant is also proper to train Hedge-fashion to hide any disagreeable fence, and will grow either under trees in the shade, or in an open exposure, and is of quick growth; and to form a Hedge, may be planted in one row, at about eighteen inches to three feet distance, according to the size of the plants at the time of planting.

The laurustinus, being valuable not only as an ever-green, but as one of our most beautiful flowering shrubs, will form a delightful Hedge for ornament, as it will be covered with flowers in winter and spring; it is also excellently adapted for training hedge-fashion against any shabby fence or naked wall. Planting it in either method, in one row, at from about eighteen inches to three feet distance.

The phillyrea and alaternus are very beautiful ever-greens for ornamental Hedges, both of which plants greatly resemble each other; but the phillyrea being the strongest grower, as well as thickest shooter, is the most eligi-

ble for a hedge, but for variety both may be used: they are also some of the best ever-green shrubs for training hedge fashion, against any unsightly or naked wall or paling fence, which they will soon cover; and if the common green and variegated kinds are intermixed, in either mode of hedge-work, they will have a delightful effect, and may be trained as detached Hedges, six or eight feet high, and against any fence ten or twelve.

Plant them in one row, at from about fifteen or eighteen inches to two or three feet distance between plant and plant.

The bay will also form a tolerable ever-green Hedge for variety, and may be led up six or seven feet high; placing the plants half a yard distance.

The ever-green oak is a proper plant to form a tall hedge, as it may be trained fifteen or twenty feet high, if required; plant it in one row, setting the plants one, two, or three feet asunder, according to their size.

The ever-green privet will also form a tolerable good Hedge five or six feet high, planting the sets about a foot asunder, and train it up narrow at top.

The tree-box makes a very close and beautiful low ever-green hedge, about four or five feet high, planting them a foot asunder.

The other lesser sorts of ever-greens mentioned in the list for ever-green Hedges, are sometimes employed for variety to form moderate Hedges, at from about three or four to five or six feet high; planting them in a row at about from twelve or eighteen inches to two feet asunder.

All the sorts of ever-greens here specified for Hedges, are raised for sale at all the nurseries; and when from about twelve or eighteen inches to two or three feet high, are of proper size for that purpose.

The season for planting them is in autumn or in spring; for it is not safe to transplant ever-greens in the middle of winter.

With respect to the mode of planting all the above sorts of ever-greens, for middle or internal Hedges; no ditch nor bank is necessary, as for outward Hedges for fences; so that in the place where the Hedge is designed, mark out a sort of border the whole length, two or three feet wide, and dig or trench it all the way along, for the reception of the plants: the plants need only be planted in a single row; observing, that if the plants are small, and that you would have them meet and form a hedge as soon as possible,

sible, you may plant them at from about a foot to fifteen or eighteen inches asunder; but if the plants are two or three feet high, and proportionably spreading, from about eighteen inches to two or three feet, may be a proper distance; and as to the method of planting, if they are small plants, they may be planted in trenches as directed in planting Hedges for fences; but if large plants with spreading roots, they may either be trenched in as you proceed in digging the ground, or holed in, plant and plant; the opening of one hole fills up that immediately before it, about the roots of the plant placed therein; and so proceed hole and hole to the end, placing all the plants upright, at regular distances, tread the earth close about their roots, and make their heads range evenly.

Deciduous Kinds.

The proper deciduous trees and shrubs for internal Hedges in gardens, besides the sorts already treated of for outward Hedges are: Hornbeam—Beech—Elm—Lime-tree—and Alder: all of which are proper either for middling or tall hedges, as they may be trained up from about six or eight to fifteen or twenty feet high; and the elm to double that height, if required. Privet is also sometimes used for moderate Hedges. And for low Hedges the Rose—Sweet-briar—Honeysuck—Syringa—Berberry, and several other low-growing deciduous shrubs, for variety.

The hornbeam forms one of the most beautiful summer Hedges of the deciduous tribe, it being a moderate, but very close shooter, well furnished with leaves; and may be trained up from about six or eight, to twelve or fifteen feet high; but the leaves, although they wither in autumn, remaining firmly attached to the branches all winter, they make but a shabby appearance during that season: it is, however, a fine Hedge, and the singularity of its retaining its withered leaves in winter, renders it superior to most other deciduous Hedges for the purpose of forming shelter in the winter time, see *CARPINUS*. Plant it for a Hedge in a single row, at about half a yard asunder, if required to form a close moderate Hedge as soon as possible; but if you design to lead up the Hedge pretty tall, set the plants about three or four feet distance.

The beech also forms a very close regular Hedge, from about six or eight, to fifteen or twenty feet high: the leaves withering on the

branches in autumn, continue dropping off most part of the winter. Plant it as directed above for the *HORNBEAM*.

The elm will form a very close, even, and beautiful Hedge, provided the upright English elm is planted, it being the properest of all elms for this purpose; and may be trained from six or eight, to thirty or forty feet high, forming a close Hedge from the very bottom to top. It is planted in a single row, from about a yard to six or eight feet distance; but when required to form a close middling Hedge as soon as possible, you may set the plants but two feet or a yard asunder; and if intended for a moderately tall Hedge, plant them three or four feet apart in the row; and if designed to have a Hedge of considerable height, place the plants five or six feet distance at least, but if eight or ten the better; as, if the plants of a very tall Hedge stand too close, they are apt to get naked at bottom.

The lime-tree is sometimes employed for ornamental Hedges for variety, but is greatly inferior to any of the other deciduous kinds, as it becomes thin and shabby by clipping, and is thinly leaved; which also begin to fall off very early in autumn.

The alder, as it delights in moist soils, and watery places, is sometimes planted for Hedges in low moist parts of gardens, where other trees will not prosper, and makes a handsome Hedge, from about six or eight, to twelve or fifteen feet high, retaining its leaves late in autumn, and continuing a fine green to the very last. See *BETULA ALNUS*.

Privet is frequently planted for Hedges, as it grows exceedingly close, may be trained up five or six feet high, and will grow anywhere; either in an open exposure, or in the shade, or under trees, and even in the midst of great cities, and soon grows up.

As to the other low kinds of shrubs mentioned in the list of deciduous garden Hedges, they are sometimes employed for variety, and some sorts, such as roses, honeysuckles, and syringa, formed into low Hedges, will, besides their property as Hedges, produce vast quantities of flowers.

With respect to the method of forming all these kinds of deciduous Hedges, the plants for that purpose are all raised as directed under each respective genus, or may be had from the nurseries; and when from about one foot to a yard or more high, according to the sorts, are of a proper size for that purpose; for it is eligible to plant them young, choosing

chusing such that are well furnished all the way with plenty of side or lateral shoots, that they may form a close Hedge quite from the bottom; and all of which may be planted any time from October till March, in open weather.

As to the method of planting, nearly the same is to be observed as directed for the ever-green kinds.

Of Training the above different Sorts of Hedges.

As to the method of training the Hedges, both ever-green and deciduous kinds, they, while young, must be but sparingly topped, till they arrive at their intended height: cutting each side, however, moderately every summer with garden shears, to train them in the proper form, and cause them to throw out plenty of lateral wood to thicken; but as to the top, only just trim the ends of the running shoots a little even, and to promote their emitting latterals to thicken gradually as they advance in height; and as some plants will advance considerably faster in height than others, let those be trimmed within the bounds of regularity, which is all that should be done till the Hedge has attained nearly its designed height: observing in training up the different Hedges to keep the top gradually a little narrower than the bottom; but more particularly those of the most pliant growth, especially some of the ever-green kinds, otherwise when broad at top, they catch much snow in winter, the weight of which would break the more pliant sorts much out of form.

All full trained Hedges, in order to preserve them in proper form, close and neat, must be clipped, both on the sides and top, once or twice a year, but never less than once; and the best time of the year for this work is summer, from about the middle or latter end of June to the end of August; for then the Hedges will have made their summer shoots, which should always, if possible, be clipped the same season while in leaf, and before the shoots become hard, whereby you will be able to perform the work more expeditiously, and with greater exactness; for regular Hedges should be cut as even as a wall on the sides, and the top as straight as a line: observing after the hedge is formed to its proper height and width, always cut each year's clipping nearly to the old cut of the former year, particularly on the sides, for by no means suffer them to grow above a foot or two wide, nor suffer them to advance upon

you too much at top, where it is designed, or necessary to keep them to a moderate height.

But to keep Hedges in perfect good order, they should be clipped twice every summer: the first clipping to be about Midsummer, or soon after, when they will have made their summer shoot; and as they will shoot again, what may be called the autumn shoot, the second clipping is necessary towards the middle or latter end of August, and they will not shoot again that year.

However, when it does not suit to clip them but once in the summer, the clipping should not be performed until the beginning of August; for if cut sooner, they will shoot again, and appear almost as rough the remainder of the summer and all winter as if they had not been clipped at all.

Very high Hedges are both troublesome and expensive to cut. The clipping is sometimes performed by the assistance of a high machine-scaffolding, or stage, twenty or thirty feet high, or more, having platforms at different heights for the men to stand upon, the whole made to move along upon wheels: it is composed of four long poles for uprights, well framed together, eight or ten feet wide at bottom, narrowing gradually to four or five at top, having a platform or stage at every seven or eight feet height, and one at top of all; and upon these the man stands to work, each platform having a rail waist-high to keep the man from falling; a sort of a ladder formed on one side for the men to ascend, &c. and at bottom four low wheels to move it along: upon this machine a man may be employed on each stage or platform, trimming the Hedge with shears, and sometimes with a garden hedge-bill fixed on a handle five or six feet long, which is more expeditious, though it will not make so neat work as cutting with shears; so as they proceed in cutting, the machine is moved along upon its wheels. But sometimes, instead of the above machine, high clipping is performed with multiplying spring, or ballance-shears: i. e. shears fixed nearly horizontal upon the end of a long pole, six, eight, or ten feet long, and which is made to fix into another occasionally, by means of iron rings, and this into a third, &c. according as you advance in height with the clipping; so that the shears by means either of a spring, or by a knob of iron forged to the back of the lower blade, for a weight, are made to open of themselves,

themselves. Then having a long string reaching from a small bent iron handle of the shears, all the way down the sides of the poles through small rings; and by holding the pole in one hand, resting the lower end on your knee or foot, and pulling the string, the shears are struck close, so as to cut the shoots of the Hedge; and at each stroke the shears open again, ready for another: this however is very tedious, as well as tiresome to the workman, and only the sides of the hedge can be trimmed; but these very high hedge-works, on account of the great trouble of clipping, and the preference given to rural growth, are become in disrepute; and, in most places, the trees which formed them are suffered to grow in an open natural way.

HEDYSARUM, French Honeyfuckle.

The plants are principally of the herbaceous tribe; and there are many species, but not more than two common to the English gardens; a hardy biennial and perennial, both of the flowery race, producing stalks two or three feet high, adorned with pinnated and trifoliate leaves, and papilionaceous flowers in long spikes.

Class and order, *Diadelphia Decandria*.

Characters.] CALIX, is monophyllous and half five-parted. COROLLA is papilionaceous of four petals, an oblong oval, compressed, emarginated, reflexed vexillum; two oblong, narrow, erect wings, and an obtuse carina, bifid at the base. STAMINA, ten diadelphous filaments, and roundish antheræ. PISTILLUM, a small narrow germen, awl-shaped, reflexed style, and single stigma. PERICARPIUM, a jointed pod, each articulation containing one reniform seed.

The species commonly cultivated in our gardens are:

¹HEDYSARUM *Coronarium*.

Common biennial French Honeyfuckle.] Hath large deeply-striking biennial roots; upright, hollow, smooth, very branchy stalks, three or four feet high, garnished with pinnated leaves, of five or six pair of foliola, terminated by an odd one; and from the places of the leaves, long spikes of beautiful red flowers, succeeded by jointed seed-pods.

Variety.] With white flowers. Both these varieties are biennial, rising one year from seed, flowers the next, and then perish.

²HEDYSARUM *Canadense*.

Canadian perennial Hedysarum.] Hath long deeply-penetrating perennial roots, crowned

with simple radical leaves, slender stalks two feet high, garnished with trifoliate or three-lobed leaves, and long loose spikes of flowers from the sides and ends of the branches, succeeded by jointed triangular seed-pods.

Varieties.] Canadian hedysarum, with red flowers—with white flowers—and with purple flowers.

Both these species of *Hedysarum* and respective varieties flower in June and July, are exceedingly floriferous, particularly the biennial sort, and are productive of plenty of ripe seed in autumn, and from which all the sorts may be raised abundantly in the common ground.

The first species and variety are biennials, and very ornamental plants for large borders, and to intermix in the shrubby compartments, allowing them room, for they branch out greatly every way, producing a vast profusion of flowers; observing, as both the varieties are biennial, a supply must be raised annually from seed.

The second sort and varieties are perennial in root, but annual in stalk: they are proper ornaments for large flower borders, and to interperse in the shrubbery clumps: allow them a dryish soil.

Propagation, &c.

All the sorts are propagated by seed, sowed in March or April, in a bed or border of common earth, for transplantation.

Sow each sort separate, either in drills half an inch deep, or on the surface, and rake them in. When the plants are come up two or three inches high, prick them out into another bed or border, six inches asunder, giving water directly, and repeat it as occasion requires, till they have taken root, and begin to grow: here let them stand till October, then transplant them into the places where they are to remain to flower, which they will effect the following summer.

Observe that as the biennial sort totally perish soon after flowering, a fresh supply must be raised from seed every spring; but the perennial sort being abiding in root, sends up new flower-stalks annually.

HELIANTHUS, *Sun-flower*.

This genus comprises several hardy herbaceous flowery annuals and perennials, and an esculent root; most of them rising with upright strong stalks, several feet high, adorned with large simple leaves, and terminated by large compound radiated flowers.

Class

Class and order, *Syngenesia Polygamia Superflua*.

Characters.] CALIX is composed of many oblong imbricated leaves, broad at their base, and pointed at the top. COROLLA is a compound radiated flower, having numerous tubular hermaphrodite fruitful florets in the disk, and the border or radius composed of long, flat, female, barren florets. STAMINA, five crooked filaments in each hermaphrodite floret, and tubulous antheræ. PISTILLUM, in the hermaphrodites, an oblong germen, slender style, and reflexed stigma. PERICARPIUM, none; an oblong four-cornered seed, succeeds each hermaphrodite floret, resting on the general receptacle.

This genus comprises—The Annual Sun-flower—Perennial Sun-flowers—and the Jerusalem Artichoke.

The species principally cultivated in our gardens are :

¹HELIANTHUS *Annuus*.

Annual Sun-flower.] Hath large fibrous roots; an upright strong stalk, rising from about half a yard, to ten or twelve feet high, branchy near the top, garnished with large oblong heart-formed trinervous leaves; and the main stem and every branch terminated by one large radiated yellow flower, nodding a little downward.

Varieties.] Giant Sun-flower, growing from about five or six to ten or twelve feet high—Dwarf Sun-flower, growing from about half a yard to a yard high; and of each variety there are singles, and doubles, with deep yellow flowers, and with sulphur-coloured flowers: the doubles of each sort are very beautiful, and are rendered double by the radius, see *COMPOSITUS flos*. They all flower in July, August, and September.

²HELIANTHUS *Multiflorus*.

Multiflorus or *Many-flowered perennial Sun-flower.*] Helianthus with fibrous perennial roots, many upright stalks, branching numerous three or four feet high, garnished with heart-shaped leaves below, and oval above; and all the stalks, branches, and side shoots, terminated by largish bright yellow flowers.

Varieties.] Single-flowered perennial Sun-flower—Double perennial Sun-flower, rendered double by the radius.

This species is the common perennial Sun-flower, sometimes called Everlasting Sun-flower; a very floriferous plant, continuing a constant succession of bloom from July until November; the double-flowered variety

is the most valuable; the flowers being perfectly full and doubled to the very centre.

³HELIANTHUS *Decapellus*.

Ten-petalous Perennial Sun-flower.] Produces many stalks three or four feet high, spear-shaped leaves, and yellow flowers, having but ten petals in the radius.

⁴HELIANTHUS *Giganteus*.

Giant Perennial Sun-flower.] Produces many erect stalks, eight or ten feet high, spear-shaped, alternate leaves, rough and ciliated at the base, and many single yellow flowers; having about twenty petals in the radius.

⁵HELIANTHUS *Atrorubens*.

Dark Red-disked Perennial Sun-flower.] Produces several stalks three or four feet high, garnished with oval, crenated, trinervous leaves, and flowers having dark red middles, and the calycinal scales erect.

⁶HELIANTHUS *Tuberosus*.

Tuberous-rooted Perennial Sun-flower, commonly called Jerusalem Artichoke.] Hath a large tuberous, knobbed, irregular, eatable root, like a potatoe; upright stalks, six or eight feet high; large oval-cordate triple-nerved leaves, and the stalks terminated by smallish yellowish flowers.

The flowers of all these species are of the compound radiated kind; many tubular florets compose the disk, and long flat ones the radius or circumference, and which, in the annual sort in particular, is succeeded by abundance of fine large seed in autumn, occupying the whole disk, or middle of the flower; for the female florets in the radius being imperfect, are never followed by seeds. See the *Characters*. The name Sun-flower, is chiefly derived from the annual sort, which is said to be given, because the flower obeys the motion of the sun, turning with its face always thereto, but more probably from the resemblance of its rays, to the figure of the radiant beams of that planet.

All the sorts, except the last, have fibrous roots, and by which the perennial sorts multiply greatly; but the sixth sort hath a knobby fleshy root, which also multiplies exceedingly, so as often to become troublesome like a weed: the annual sorts are but of few months duration; but the perennials are of great duration in root, but annual in stalk.

They are all originally of America; but have been long in our gardens, especially the first, second, and sixth species, and are all so hardy as to grow here in any soil and exposure.

They

They are proper ornamental furniture for the common compartments of the pleasure-ground, arranging them rather backward, among the taller classes, where they will effect a good variety with their bloom, in one or other of them, from July until November.

The annual sorts are stately majestic plants, of amazing quick growth, as some of the giant sorts will sometimes in a strong rich soil, arrive at ten or twelve feet height in four months, and produce flowers from ten or twelve to eighteen inches diameter, and make a noble appearance, especially the full double kinds. But the dwarf kind being rather remarkable for having the most doubles, and these generally more double than the giant sorts, they are the most esteemed for general culture, and are more particularly adapted for small gardens; though in large gardens some of each sort is proper: and both varieties, if growing separate, remain tolerably permanent, as the seed of each will produce plants of the same sort again.

These fine plants are of no more than about six months duration, being raised from seed in spring, arrive at full growth in July and August, and die wholly in October or November; so that a fresh supply must be raised every spring.

All the perennials are of great duration in root; but their stalks decay in autumn, and new ones rise in spring.

Of the perennial sorts, the *Helianthus Multiflorus* has considerably the greatest merit for ornament, the flowers being larger and more numerous than any of the others, and very double, and is the sort commonly cultivated; but the other sorts may be admitted in a collection to increase the variety. All of which may be had at most of the nurseries; but the *Helianthus Tuberosus* should be but sparingly admitted in compartments amongst other plants, for its roots will multiply so greatly, as soon to over-run the ground.

The *Helianthus Tuberosus* is by many esteemed for its roots to eat, which is large, solid and fleshy, somewhat resembling a potatoe, and sometimes as large, but much more knobbed and irregular, and greatly inferior to that root as an esculent, it being rather of a watery and insipid nature, though some are remarkably fond of them: they are com-

monly boiled and served up with plenty of butter.

This sort is commonly called Jerusalem Artichoke, though with very little propriety, for the plant grows no where naturally about Jerusalem, nor is it in the least allied in any respect to *Cynara*, or Artichoke.

Propagation, &c.

The propagation of all the sorts is very easy; the first species and varieties by seed, and all the others by roots.

The first species, therefore, and varieties, are raised from seed, sowed annually in March or April, either in the borders, or other places where you design they shall flower, in patches, three or four seeds in each, about an inch deep, and when the plants are an inch or two high, thin out the worst, leaving only one of the best plants in each patch; or sow them thin in a bed or border, and when the plants are two or three inches high, transplant them, in moist weather, where they are finally to remain; or if you would bring them as forward into bloom as possible, the seed may be sowed on a moderate hot-bed under a hand glass, giving plenty of air in mild weather, and plant them out in May.

The perennial kinds are propagated plentifully by dividing the roots, any time from October or November, till March: the four fibrous-rooted sorts may be slipped into small heads, and planted at once where they are to remain; they will flower the following summer, and will be increased greatly by autumn: and as to the tuberous-rooted kind, the large roots may either be divided into pieces, or plant the small roots, every bit having an eye; they will readily grow, and multiply greatly in one year.

But when designed to raise the tuberous *Helianthus*, or Jerusalem Artichoke as an esculent, it should be planted in an open spot of light ground in the kitchen garden. In spring having procured some large roots, they may be cut into four pieces; each making a set or plant; or, in default of large ones, may use small ones whole. They are to be planted with a dibble, in rows three feet and a half asunder, planting them four or five inches deep, and half a yard distance in each row; and, when planted, rake the ground even; and keep it clean from weeds by broad hoeing. The plants will come up in April or May, and shoot up into stalk six, or eight feet

feet high, which in the end of July, or beginning of August, may be cut down half way, the better to admit the benefit of the air, rains, and dews to the roots to increase their bulk.

They will be fully grown by September, when some may be taken up for use; and about the end of that month, or in October, take them wholly out of the ground, and lay them in sand in a dry place, for winter service.

HELIOTROPIUM, *Heliotrope*, or *Turnsole*.

This genus comprises a few herbaceous annuals, and some shrubby plants, all tender exotics; one of the latter is cultivated here as a green-house shrub.

Class and order, *Pentrandria Monogynia*.
Characters.] **CALIX** is monophyllous, and five parted at top. **COROLLA**, is monopetalous, divided into five unequal parts. **STAMINA**, five filaments, and small antheræ. **PISTILLUM**, four germina, slender style and notched stigma. **PERICARPIUM**, none, oval seeds lodged in the calix.

The species chiefly cultivated here is:

HELIOTROPIUM *Peruviana*.

Peruvian Sweet-scented Heliotrope.] Hath a shrubby stalk, branching numerously four or five feet high, spear-shaped, oval, rough, veined, hairy leaves, about three inches long, and one broad, placed sparsely; and from the ends of the branches, numerous clustered spikes of pale blue, sweet-scented flowers, appearing great part of the year, and succeeded by ripe seeds in autumn.

This plant must be always kept in pots to move into the green-house in winter; and must be potted in any light rich garden-earth.

It is propagated easily by seed, and cuttings of its young shoots.

By Seed.—This ripens here: sow it in pots of light earth in spring, and plunge them in a hot-bed; and when the plants are two or three inches high, plant them in separate small pots, plunging them also in a hot-bed to strike; then inure them gradually to the full air.

By Cuttings.—Plant small cuttings of the young shoots in spring or summer in pots, and if plunged in a moderate hot-bed will sooner take root.

HELLEBORUS, Black Hellebore, &c.

This genus retains a few hardy herbaceous perennials for ornament and medical pur-

poses, obtaining in stature, some not more than three or four inches, others from one to two feet, adorned with many-lobed, and hand-shaped leaves, and pentapetalous flowers.

Class and order, *Polyandria Polygynia*.

Characters.] **CALIX**, none. **COROLLA**, five large roundish petals, and many small nectaria placed circularly. **STAMINA**, numerous filaments, and compressed erect antheræ. **PISTILLUM**, several compressed germina, awl-shaped styles, and thick stigmas. **PERICARPIUM**, several bicarinated capsules, having the lower carinas shortest and the upper convex, and many round seeds.

This genus comprises—The True Black Hellebore, or Christmas Rose—Winter Aconite—Wild Black Hellebore, or Bear's-foot, &c.

The species are:

¹**HELLEBORUS**, *Niger*.

True Black Hellebore, commonly called Christmas Rose.] Helleborus with roots composed of many thick, fleshy, spreading fibres, crowned by a large cluster of lobed leaves, consisting each of seven or eight obtuse, fleshy lobes, united to one foot-stalk; and between the leaves several thick fleshy flower-stalks three or four inches high, surmounted by large beautiful white flowers of five large roundish petals, and numerous filaments, appearing in winter, about, or soon after Christmas.

This is the true black Hellebore of the ancients; the root is used in medicine, and is a strong purgative.

²**HELLEBORUS** *Hyemalis*.

Winter Aconite, formerly a species of Aconitum (Aconitum Hyemale).] Hath a small, bulbous, brown root, sending up small foot-stalks two inches high, each supporting one leaf, divided into many parts, and small golden yellow flowers sitting in the bosom of the leaves; appearing in January or February.

³**HELLEBORUS** *Foetidus*.

Stinking Great Wild Black Hellebore, or Bear's foot.] Hath large fibrous roots, upright smooth stalks dividing into bushy heads, and branching two feet high, garnished with large pedated dark-green leaves of about nine long, narrow, serrated folioles, ending in acute points, and at the ends of all the branches numerous greenish flowers tipped with purple; appearing early in winter, and succeeded by plenty of seeds in the spring.

*HELLEBORUS *Viridis*.

Green-flowered Wild Black Hellebore, or Bear's foot.] Hath thick fibrous roots, crowned with large digitate or fingered dark-green leaves, of nine long, narrow, serrated lobes; upright firm stalks a foot high, garnished with smaller leaves; and from the top many green flowers intermixed also with leaves: appearing in January and February, succeeded by plenty of seed in May.

All these four species are hardy herbaceous perennials, of which the third and fourth sorts remain bushy and green the year round, more particularly the third; and all the sorts are so hardy as to succeed in any common soil of a garden: the first should rather have a warm situation, but all the others will prosper any where; and the third and fourth either in an exposed situation, or under the shade of trees; so are proper to mix in shrubberies and wilderness quarters.

The flowers of all the sorts are composed of five roundish petals, and numerous filaments; those of the *Helleborus Niger* are considerably the largest and most beautiful of all the sorts.

All the species may be employed as plants of ornament to adorn the flower borders, and other parts of the pleasure-ground.

They are cultivated by the nurserymen for sale, and their propagation and culture is very easy.

The first sort, *Helleborus Niger*, possesses great merit, both for the singularity of its profusion of bloom, in the midst of winter, and for the great beauty of its flower; which being large, and bearing some resemblance to a single white rose, and appearing often about Christmas time, derived the appellation of Christmas Rose: it prospers in the open borders, or may be planted in pots, to move when in bloom to adorn any particular place; observing it always flowers fairest and the most abundantly in the front of a warm sunny border. The plants may be transplanted, and the roots divided for propagation in autumn, i. e. September, October, or November; but the sooner in autumn it is done, the stronger they will flower at their proper season towards spring; or they may be removed in spring, after they have done flowering.

Its propagation is effected commonly by parting the roots; also by seed, when they ripen, which happens but seldom in this country.

But as being a fibrous-rooted perennial encreasing in root, by off-sets, or slips, its propagation is easily effected by dividing the root into slips in autumn, or in spring, after the flower is past, not too small, planting them in a sheltered border, and they will flower at their proper season.

The second sort, *Helleborus Kyemalis*, or Winter Aconite, is esteemed for its early bloom, which though a diminutive plant, almost the smallest of the bulbous-rooted tribe, yet it exhibits its golden flowers very ornamentally early in spring, when few others are to be seen; and is a very proper plant to adorn the edges of borders, and other flower compartments, in assemblage with snowdrops, &c. placing them in patches alternately, several roots in each patch; otherwise, as the plants being small and near the ground, if not planted in clusters, they will not make any considerable shew: plant, therefore, five or six roots at least in each patch of four or five inches diameter, putting them two or three inches deep; where they may remain undisturbed three years, or till encreased into large bunches, then taken up and separated.

The roots being bulbous, they are transplanted when their leaves decay, from June till October, and they encrease fast by off-sets like other bulbs; which may be taken up and separated every two, three, or four years, for propagation.

The third and fourth species being large, bushy, ever-green, very hardy perennials, particularly the *Helleborus Foetidus*, flowering in the midst of winter, and early in spring in any weather, effect a good variety at all seasons; but although the flowers are not elegant, yet the plants appearing always green, of a robust aspect, and flowering at a time of year when hardly any others appear in the open air, renders them proper ornaments for large borders, particularly in shrubbery and wilderness plantations, as they will prosper between shrubs, and under the shade of trees, &c. they being natives of woods in several parts of England, and may be raised in great plenty from seed; and from scattered or self-sown seeds many young plants will rise.

They are also both medical plants, and for which use great quantities are raised in many gardens about London to supply the markets.

Both these sorts are propagated by seed sown as soon as ripe, or any time from March till

till September, though spring is the best season. The seeds may be had of all the nursery and seedsmen. Sow it in beds of common earth, and rake it in; and when the plants are three inches high, plant them out in beds a foot apart; and after having two or three months growth there, transplant those intended for ornament where they are to remain; but those raised for medical use, may remain in the beds.

These plants may be removed either in spring or autumn, or even in winter, as they will readily rise with balls about their roots.

HEMEROCALLIS, Day Lily, or Lily-Asphodel.

Two herbaceous flowery perennials for the pleasure-ground; producing very long, narrow, radical leaves, and naked annual stalks two feet high, adorned at top with large, liliaceous, six-parted, yellow and red flowers.

Class and order, *Hexandria Monogynia*.

Characters.] **CALIX**, none. **COROLLA**, is an infundibuliforme campanulated petal, with a short tube, and the limb deeply cut into six parts, which are spreading and reflexed. **STAMINA**, six awl-shaped declinated filaments, and long incumbent antheræ. **PISTILLUM**, a roundish sulcated germen, filiforme style, and three-cornered stigma. **PERICARPIUM**, an oval, trigonal, trilobous, trilocular capsule, and numerous roundish seeds.

The *Liliastrum*, or St. Bruno's Lily, formerly of this genus, is removed to the genus *Anthericum*, its character determining it a species of that genus, see **ANTHERICUM Liliastrum**.

The species, therefore, now of this genus are:

¹**HEMEROCALLIS Flava.**

Yellow Day Lily.] **Hemerocallis**, with strong fibrous roots, furnished with oblong yellowish tubers; sending up keel-shaped hollow leaves two feet long; upright leafless firm stalks two feet high, dividing at top into several foot-stalks, each terminated by one large liliaceous yellow flower, of an agreeable odour.

Variety.] Small yellow Day Lily. (*Hemerocallis minor*.)

²**HEMEROCALLIS Fulva.**

Reddish, or Copper-coloured Day Lily.] Hath roots composed of strong fleshy fibres, and large oblong tubers; radical, keel-shaped, hollowed, pointed leaves, a yard long, reflexed

at top; and upright thick leafless stalks, three or four feet high, dividing at top into branches, terminated by large copper-coloured liliaceous flowers, having large long stamina, charged with fulvous coloured farina, which being touched or smelled to, is discharged in great plenty over the hands or face.

Both these species are very hardy, succeed any where, and multiply at a great rate by their spreading roots; which are perennial, but annual in leaf and stalk: they derive the name, Day Lily, from the diurnal duration of their flowers, and by being succeeded by new ones daily on the same plants for a fortnight or three weeks.

The flowers are of the Lily form, each of one petal, deeply cut into six parts. See the *Characters*.

They both flower in June, and ripen seeds in August.

Both the sorts are proper furniture for large borders, and other compartments of the pleasure-garden, and may be planted in autumn, or any time in open weather, from September till March.

Their propagation is effected abundantly by parting the roots, for they increase greatly by off-sets, which may be divided in autumn, or almost any time after flowering, or before they begin to shoot in spring; and each slip will flower at the proper season.

They may also be raised from seed, sown soon after they are ripe, in a bed of common earth, and raked in: the plants will come up in spring following; prick them out in nursery beds in summer, and some of the strongest will flower the second year.

HEPATICA, Noble Liverwort, now a species of *Anemone*. See **ANEMONE Hepatica**.

HERBA, an Herb. All vegetables which rise with leaves and stalks annually from the root, without becoming woody and durable, are properly considered as Herbs; such, for instance, are many of the kitchen-garden esculents, and medical plants; and a vast train of the ornamental or flowery tribe may also come under that denomination. See **HERBACEOUS PLANTS**.

But many of the undershrubby esculent and medical plants are also sometimes considered as Herbs; such as sage, thyme, rue, hyssop, winter-savory, lavender, &c. but these having ligneous, durable stalks and branches, are more allied to the shrubby tribe, so are properly of the under-shrubby kind. See **SUFFRUTICOSUS**.

HERBACEA Planta. Herbaceous plants, or vegetables of an herb-like nature.

All vegetables that produce leaves and stalks annually from the root, and whose stalk or stems remain green and succulent, or soft, not becoming woody, nor durable, but die down to the root every year, soon after they have produced flowers, &c. are properly Herbaceous Plants; and of which there are annuals, biennials, and perennials. Annuals are such which perish, stem, root and all, at the end of the year; biennials subsist two years, generally perishing as soon as they have flowered; perennials are perpetuated by their roots producing new stems every year for the purpose of producing flowers and seed.

So that Herbaceous vegetables are very distinguishable from the woody kinds, such as trees, shrubs, and under-shrubs, whose stems and branches are woody or ligneous, and durable; and the stalks of the Herbaceous tribe perish annually, or at least as soon as they have flowered, and perfected their seeds, and the same individual stalk never lives to flower again, but dies in autumn; and in annuals, and biennials, root and all; but perennials surviving by the root, send up fresh stalks in spring.

Of the Herbaceous tribe are most of the esculents of the kitchen-garden, except those of the under-shrubby kinds, such as sage, thyme, hyssop, &c. vast numbers of the medical plants are also Herbaceous; and of the flowery kinds for the pleasure-garden, almost all the annuals and biennials are herbaceous; as also all the perennials, both the fibrous, bulbous, and tuberous-rooted kinds, whose stalks decay annually, are likewise Herbaceous Plants. Therefore Herbaceous Plants compose a very considerable part of the vegetable creation.

HERMANNIA, *Hermannia*.

This genus consists of shrubby exotics for the green-house, growing from about half a yard to six or seven feet high, adorned principally with smallish simple foliage, and quinquepetalous flowers, in numerous spikes.

Class and order, *Monadelphia Pentandria*.

Characters.] **CALIX**, is monophyllous, five-parted at the brim, inflexed and permanent. **COROLLA**, five petals spirally twisted contrary to the apparent motion of the sun, broad and spreading above. **STAMINA**, five monadelphous filaments, and acuminate connivent antheræ. **PISTILLUM**, a roundish pentangular germen, awl shaped style, and simple

stigma. **PERICARPIMUM**, a roundish five-cornered quinquelocular capsule, and many small seeds.

The species that are principally cultivated are:

¹**HERMANNIA *Lavendulifolia*.**

Lavender-leaved Hermannia] Hath a shrubby stalk and slender branches, very bushy, about a foot and a half high; small, spear-shaped, obtuse, hairy leaves, and clusters of small yellow flowers along the sides of the branches, from June till autumn.

²**HERMANNIA *Althæifolia*.**

Althæa-leaved Hermannia] Hath a shrubby stalk, and soft woolly branches, growing two feet high, ovalish, plaited, crenated, woolly leaves, and numerous yellow flowers, in loose spikes at the ends of the branches, in June and July.

³**HERMANNIA *Grossularifolia*.**

Gooseberry-leaved Hermannia] Hath a shrubby stalk and spreading branches, growing three or four feet high; spear-shaped, pinnatifid, small, close-fitting leaves, and bright yellow flowers, by twos on each foot-stalk, numerous at the ends of all the shoots and branches, in April or May.

⁴**HERMANNIA *Alnifolia*.**

Alder-leaved Hermannia] Hath a shrubby stalk and branches, growing irregularly four or five feet high; wedge-shaped, plaited, crenated leaves; and pale yellow flowers in short spikes from the sides and ends of the branches, in April and May.

⁵**HERMANNIA *Hyssopifolia*.**

Hyssop-leaved Hermannia] Hath a shrubby upright stalk branching, out laterally, six or seven feet high; smallish, spear-shaped, obtuse, serrated leaves; and pale yellow flowers in clusters from the sides of the branches, in May and June.

All these five species are African shrubs, but succeed here with the protection of a green-house in winter, so must be potted in pots of rich garden mould, and managed as other green-house shrubs. See **GREEN-HOUSE PLANTS**.

They are ever-green, and mostly of bushy growth, and produce a vast profusion of flowers in April, May, and June.

The propagation of all the sorts is by cuttings of their young shoots, any time from April till July, planted in pots of rich earth, which if plunged in a moderate hot bed, they will soon strike; and those planted in summer will also strike without the aid of hot-beds, even in

H E R

in beds of common earth, watered and shaded occasionally; and when rooted and begin to shoot, transplant them each into a small pot.

They may also be raised from seeds; but this is seldom produced good here; it is procured from abroad, and must be sowed in pots, and placed in a hot-bed.

HERMAPHRODITUS *Flos*. Hermaphrodite Flower. A flower furnished with both the male and female organs of generation, i. e. the filaments and antheræ, the male organs; and the germen, style, and stigma, as the female; all of which being contained within the same calix and corolla, as in most, they are denominated Hermaphrodite Flowers.

Of this kind of flower, are those of all the classes, except *Monoecia* and *Dioecia*; in the former of which, male and female flowers, having each its distinct parts, are produced separate on the same plant; in the latter on distinct plants; and in the class *Polygamia*, there are always Hermaphrodites mixed with the males, or females, or both, either on the same, or separate plants; and in the class *Syngenesia*, which comprehends the numerous tribe of compound-flowers, and in which sometimes the flower is composed entirely of Hermaphrodite florets, and sometimes Hermaphrodite and females, and frequently Hermaphrodites and florets of no sex or neuter. See **CLASSIS**.

So that the greatest part of the vegetable creation produces Hermaphrodite flowers, either wholly, or mixed with males, or females, or both; whereby Hermaphrodites are as frequent in the vegetable, as they are rare and unusual in the animal kingdom.

Therefore remarking, that all flowers, whether simple, or composed of many florets, having both male and female organs within the same corolla, either simple, as above said, or in the corollula, or florets of a compound flower, are by botanists denominated Hermaphrodites, to distinguish them from males and females, which have each their parts distinct in their respective corolla.

And all plants producing Hermaphrodite Flowers only, are termed Hermaphrodite plants.

HERNANDIA, Jack-in-a-box Tree:

It comprises two ever-green exotic trees of the Indies, sometimes retained here in stoves for variety, adorned with very large beautiful simple foliage.

Class and order, *Monoecia Triandria*.

H E S

Characters.] **CALIX**, male and female flowers, having a partial involucre of four oval leaves, and each of the females a bell-shaped cup. **COROLLA**, is of six petals in the males, and eight in the females. **STAMINA**, three filaments, and large oblong erect antheræ. **PISTILLUM**, a roundish germen, slender style, and large half-funnel-shaped stigma. **PERICARPIUM**, the calix becomes a large roundish, swollen, hollow fruit, inclosing a hard drupaceous juiceless nut.

The species are:

¹**HERNANDIA** *Sonora*.

Sonorous Hernandia, commonly called Jack-in-a-box.] Grows twenty or thirty feet high, garnished with large broad peltated leaves, and monoecious flowers, succeeded by a large swollen, hollow fruit, formed of the calix, having a hole, or open at the end, and a hard nut within; and the wind blowing into the cavity of the fruit, makes a very sonorous whistling and rattling noise: hence the tree derived the name, Jack-in-a-box.

²**HERNANDIA** *Oviger*.

Oriental oval-leaved Hernandia.] Grows many feet high, garnished with large oval leaves, not peltated; and monoecious flowers, succeeded by swollen fruit, open at the end, and a nut within.

Both these exotics are of the tree kind, natives of the East and West Indies, where they attain a large growth; but here, being kept in stoves, they rarely grow higher than common shrubs, and very few, if any, of them have flowered or fruited.

They requiring a hot-house here, must be potted in pots of rich light earth, and always retained in that conservatory.

Their propagation is by seed, i. e. their nuts procured from the West Indies; sowing them in pots of rich earth, and plunge them in the bark hot-bed; and when the plants come up, prick them out into separate pots, plunging them also in the bark-bed.

HESPERIS, Rocket, Dame's Violet, or Queen's Gilliflower.

The plants are hardy herbaceous biennials and perennials, cultivated as flowery plants, producing annual stalks, two feet high, simple leaves, and tetrapetalous cruciforme flowers, in large spikes at top, some of which are of great fragrance.

Class and order, *Tetradynamia Siliquosa*.

Characters.] **CALIX**, is four leaved and deciduous. **COROLLA**, four oblong cruciforme.

forme petals. STAMINA, four long and two short filaments, and narrow erect antheræ. PISTILLUM, a four-cornered germen, no style, but an oblong stigma fitting on the germen. PERICARPIMUM, a long compressed plane, bilocular pod, and many oval seeds.

The most material species are ;

¹HESPERIS *Matronalis*.

Dame's Violet, or Common Sweet-scented Garden Rocket.] Hath fibrous roots, crowned by a tuft of long spear-shaped rough leaves ; upright, single, hairy stalks, two feet high ; garnished with oval, lanceolate, slightly indented, close-fitting leaves ; and the stalk and branches terminated by large, long spikes of sweet-scented flowers, of different colours and properties in the varieties.

Varieties of this are ;] Garden Rocket, with single white flowers—double white flowers—single and double purple flowers—purple and white flowers—crimson flowers. All of which are so remarkable for imparting a most fragrant odour, that the ladies were fond of having them in their apartments. Hence derived the name Dame's Violet, and bearing some resemblance to a stock-gilliflower, were sometimes also called Queen's-gilliflower ; but are now most commonly called Rocket.

²HESPERIS *Inodora*.

Scentless Rocket.] Hath fibrous roots, upright round firm stalks, two feet high, garnished with spear-shaped, acute-pointed, sharply indented, close fitting leaves, and all the branches terminated by large spikes of scentless flowers, with obtuse petals ; of different colours and properties in the varieties.

Varieties.] Scentless Rocket, with single white flowers—double white flowers—single and double purple flowers. All of which are devoid of scent, but are showy garden flowers.

³HESPERIS *Tristis*.

Dull-flowered Night-smelling Rocket.] Hath fibrous roots ; upright, branching spreading, bristly stalks, two feet high ; spear-shaped, pointed leaves ; and spikes of pale purple flowers, of great fragrance in the evening.

They are all fibrous-rooted plants, the roots crowned with a large tuft of long leaves, and produce their flower-stalks annually in spring, flower in summer, ripen seeds in autumn, and die to the root soon after.

All the three species may be deemed both biennial and perennial ; for, considered as biennials, they being raised one year from

seed, flower the next, and then frequently perish root and all, especially the singles ; but, with some care, both they and the doubles may be continued some years : and considered as perennials ; for by cutting down some of their flower-stalks as soon as the flowers begin to fade, or rather before they attain a flowering state, it often promotes their forming off-sets at bottom the same season for encrease, which being separated early in autumn, each forms a plant for next year's bloom ; and is worth practice for all the double kinds ; by which means the plants may sometimes be continued from year to year, otherwise they are rather naturally of the biennial kind ; and it is, therefore, also proper to raise some annually from seeds, as directed in their propagation.

They are all hardy, more especially the first and second species, which prosper in any of the open borders, and in any common soil of a garden ; but the third sort being rather impatient of severe frost, and much moisture in winter, should have a dry warm situation ; and place a few in pots to move to the shelter of a frame in inclement weather.

The flowers of all the sorts are formed separately of four cruciforme petals, which being numerous, and collected into large spikes, make a fine appearance, but more particularly the double varieties, which being as large and full of petals as double stock-gilliflowers, are exceedingly beautiful garden flowers.

They all flower in June and July, and ripen abundance of seed in August.

Their stalks always decay in autumn, soon after the seed are ripe.

All the sorts are very ornamental furniture for any of the open borders of the pleasure-ground, and to intersperse in assemblages with herbaceous plants, towards the fronts of the most conspicuous shrubbery clumps, contiguous to lawns and grand walks.

They may be planted out in autumn, or early in spring, before they advance much for flowering ; and with care they may be removed with balls to their roots, so as scarce to feel their removal

Propagation.

Their propagation is performed three different ways : by seeds, by off-sets of the roots, and by cuttings of the flower stalk.

By

By Seed.—This is sold very cheap at all the nurseries, and March and April is the season for sowing it; which sow in a bed or border of light earth, and either rake it in lightly, or cover it a quarter of an inch deep with light mould; and when the plants are come up three or four inches high, plant them out in beds six inches apart, to remain till October or spring following; then transplant them where you design they shall flower, which they will all effect the ensuing summer.

Observe, most of these seedlings will come single, that is, produce single flowers, and many of these go off after they have flowered; but as they may be easily raised in any quantity from seed as above, it is proper to raise a fresh supply annually to disperse in the common borders.

But as to the doubles, they are propagated with certainty only by dividing the roots, or by cuttings, as directed below.

By Dividing the Roots.—This, and the cuttings of the flower-stalks, are the only methods to propagate the double kinds, for doubles of them are but very sparingly obtained from seed; and as they are rather sparing in forming off-sets from the root for propagation, as before observed, unless assisted by art, and being likewise often apt to decay entirely, root and all, after they have flowered, as being somewhat of a biennial nature, without practising a particular experiment to promote young off-sets from the root; therefore let some good plants be set apart in any open bed or border for propagation, not suffering them to run up fully to flower; but when their flower-stalks have advanced about eight or ten inches high, cut them down close to the ground, and according as they shoot again, cut them also off; and by thus stopping their upright growth, the roots will more readily throw out young off-sets from their sides all around, which will be well formed by August, or early in September, when the whole root should be taken up, and the off-sets divided separately, and planted in a nursery-bed, six inches distance, to remain till October, or spring following, then removed with balls to where they are to stand to flower; the flower-stalks which are occasionally cut down to promote increase of off-sets at bottom, may be divided into lengths, and planted as hereunder directed; each cutting will root and form a plant for next year's bloom.

The above practice should be pursued annually to keep up your stock of doubles, for those which shoot up to full growth and bloom, rarely put out any off-sets, unless the stalks are cut down as soon as the flowers begin to fade, when sometimes they emit a few, but which will not be so many, nor so strong as by the other method.

By Cuttings of the Flower-stalks.—Having directed above to cut down the flower-stalks, when about half grown; each of these may be divided into two, so as to make two cuttings, though the lower half as being more hardened, will form the best cutting of the two; they may, however, both be planted to take their chance. Having procured a quantity of these kind of cuttings, from about three to five inches long, plant them in a shady border, putting them two parts out of three into the ground, about three inches asunder, and give water; let the watering be frequently repeated, and many of the cuttings will be well rooted, and form shoots at top in six or eight weeks: but to promote their rooting more effectually, they may be covered close with hand or bell-glasses, as soon as planted, whereby they will strike much sooner; observing when they begin to shoot at top, to raise the glasses to admit air, to which harden them fully by degrees.

Sometimes cuttings of the flower-stalks of those which have flowered, cut down as soon as the flower begins to fade, and divided into lengths, and planted as above, will also grow, though they will not produce so good plants as those formed of the young stalks early in the summer.

HIBISCUS, Syrian Mallow, or *Althæa Frutex*, &c.

This genus furnishes a hardy, deciduous, flowering shrub, and flowery annual for the pleasure-ground, and some shrubby and herbaceous exotics for the hot-house, adorned mostly with largish simple, lobated foliage, and large quinquepetalous mallow-shaped flowers.

Class and order, *Monadelphia Polyandria*.

Characters.] CALIX, is double, the outer series is of many narrow permanent leaves, and the interior of one leaf five-parted at the brim. COROLLA, five heart-shaped petals united at their base. STAMINA, numerous filaments that coalesce below, and form a column, and kidney-shaped antheræ. PISTILLUM, a roundish germen, and slender style, five-parted at top, each part having a capitated

capitated stigma. PERICARPIUM, a quinquevalvular, quinquelocular capsule, and kidney-shaped seeds.

There are many species of this genus, but not more than four or five commonly cultivated in the English gardens; of which some are hardy, and others so tender as to require a stove in this country.

Hardy Kinds.

¹HIBISCUS *Syriaca*.

Syrian Hibiscus, commonly called Althæa Frutex.] Hath a shrubby stem and branches, forming a bushy head, five or six feet high; garnished with oval, wedge-shaped, alternate leaves, cut at top into three indented lobes; and from the sides of all the young shoots, numerous, large, pentapetalous, spreading flowers, of different colours in the varieties, having all dark middles, darting out each way in radiant directions towards the extremity of each petal.

Varieties of this are;] *Althæa Frutex* with white flowers—with red flowers—pale purple flowers—deep purple flowers—with yellow flowers—and with variegated flowers, called Painted Lady *Althæa Frutex*—likewise with silver-striped leaves—gold-bloached leaves.

All these varieties are shrubby, flower in August, producing such great quantities of flowers in daily succession for three or four weeks, that the shrubs appear covered therewith, making a most delightful appearance, and are the greatest ornaments of the autumn season, of almost any of the shrubby tribe.

²HIBISCUS *Trionum*.

Trionum, Bladder Ketmia, Venice Mallow, or Flower of an Hour.] Hath an herbaceous branchy stalk, growing a foot and a half high; garnished with three-lobed leaves, deeply jagged on the edges into opposite obtuse segments; and from the joints of the stalks yellowish flowers with dark-purple bottoms, having the inner cup swollen like a bladder: hence the name, Bladder Ketmia.

This species is annual, sometimes called Flower of an Hour, (*Flos Hæra*) from the short duration of its flowers, which in hot dry weather they but just open, and wither away in an hour or two; but these are succeeded by a plentiful daily succession for a long time.

Tender Kinds.

³HIBISCUS *Mutabilis*.

Changeable-flowered Hibiscus, commonly called China Rose.] Hath a shrubby, soft, spongy stem, branching into a spreading head, rising ten or twelve feet high; adorned with heart-shaped, five-angled, serrated, shining-green

leaves, but pale underneath; and from the axillas of the stalk and branches, large, pentapetalous, spreading flowers, appearing first white, gradually changing to a blush-red colour, and from that to a purple,

⁴HIBISCUS, *Rosa Sinensis*.

Rose of China, or Double China Rose.] Hath a shrubby tree-like stem, dividing into a spreading head, rising twelve or fourteen feet high; oval, acuminate, serrated leaves; and from the sides of the branches, large red flowers, having many oblong roundish petals in several series, like a large double rose; and are exceedingly elegant, which, by way of pre-eminence, is by botanists called, the *Rose of China* (*Rosa Sinensis*.)

⁵HIBISCUS *Malvaviscus*.

Viscous Mallow, with scarlet flowers.] Hath a shrubby stalk, branching ten or twelve feet high; heart-shaped, angular, crenated leaves; and from the wings of the stalks scarlet flowers, with the petals twisted together; succeeded by roundish beautiful scarlet berries of a viscous, or clammy nature.

The flowers of all these species of Hibiscus, consist of five largish heart-shaped petals, and numerous stamina, forming a column below (see the *Characters*); and in most of the sorts the flowers are numerous and very ornamental.

Those, of all the sorts, are but of short duration, but are succeeded in most by new ones daily.

The *Hibiscus Syriacus*, commonly known by the name of *Althæa Frutex*, is originally of Syria, but so hardy that it will grow here almost any where in an open situation; and is so ornamental when in bloom, that all the varieties merit admittance into every shrubbery in the most conspicuous point of view, where the different varieties will have a most beautiful effect.

Their propagation is by seed, by layers, and by cuttings.

By Seed.—This is procured from abroad by the seedsmen; and March and April is the season for sowing it, which may either be sown in pots, and plunged into a slender hot-bed to forward them, or may sow them in a bed of light earth in a warm situation, covering it half an inch deep; the plants will soon come up, giving water in summer, and a little shelter in severe frosts; and when two years old plant them out in nursery rows.

By Layers.—Autumn is the proper time; give the shoots a little cut through the bark at one or two joints, and lay them in the usual

G R A

usual way: they will be rooted in one year.

By Cuttings.—March and April is the time to plant them: choose young shoots, which if planted in pots and plunged into a hot bed, will more readily strike; though if planted in a shady border, many of them will also put out roots.

The second sort, commonly called Bladder Ketmia, is a hardy annual of the flowery kind, and merits a place in the collection of hardy annuals in the open borders, &c.

Its propagation is by seed, which may be sowed either in autumn or spring, in the place where you design the plants shall flower, in patches, several seeds in each; leaving, however, but two or three of the best plants in each patch.

The three tender species being all natives of China, require to be continued mostly in a stove in this country; the first two of them produce flowers of the most singular beauty and elegance, equalling most of our finest roses, and both of which flower in great perfection in our stoves; and in Asia, their native soil, are some of their finest flowers: we often see them painted in many of the Chinese pieces, as also on the porcelain ware, to embellish china bowls, and other china vessels, particularly the flower of the *Hibiscus Mutabilis*.

However, as all the three species will flower beautifully here, and sometimes perfect seeds, they are worth the attention of those accommodated with hot-houses; keeping them always in pots of rich earth, and retaining them constantly in that department; for although they will succeed in the open air in the heat of summer, and in a good greenhouse in winter, yet rarely flower well without the continual shelter of the stove.

The propagation of these three tender kinds are effected by seed, and sometimes by cuttings.

By Seed.—March, April, or May, is the time to sow it, and should have the aid of a hot-bed: sow it, therefore, in pots of rich earth, half an inch deep, and plunge them in any hot-bed under glasses, or in the bark-bed in the stove; and when the plants are two or three inches high, plant them out in separate small pots, give water, and plunge them also in the hot-bed.

By Cuttings.—Plant short cuttings of the young shoots in pots, in spring or summer, and plunge them in the bark-bed.

G R A

HIERACIUM Hawkweed.

The plants are hardy herbaceous perennials; one of which is retained as a flowery plant, has oval leaves, and annual stalks a foot high, surmounted by compound-flowers in a corymbus.

Class and order, *Syngenesia Polygamia Æqualis*.

Characters.] CALIX, many narrow unequal leaves. COROLLA, many hermaphrodite ligulated florets, in one general cup, each five-parted at the top. STAMINA, five filaments and cylindric antheræ. PISTILLUM, an oval germen, slender style, and two recurved stigma. PERICARPIUM, none. SEMINA, a four-cornered seed to each floret, crowned with down, sitting in the calix.

There are many species, but not more than one usually cultivated, viz.

HIERACIUM *Aurantiacum*.

Orange coloured Garden Hieracium, sometimes called Grim the Collier] Hieracium with many oblong oval, entire leaves, crowning the root; an upright, single, hairy, almost leafless stalk, a foot high, terminated by reddish orange-coloured flowers, in a corymbus, having dark coal-ash-coloured calices, whence the cant name, Grim the Collier.

This is a hardy perennial, with fibrous durable roots, but annual stalks, which rise in spring, flower in June, continuing in succession two or three months, ripen seeds in autumn, and the stalks soon after decay.

It is proper furniture for the fronts of any of the compartments of the pleasure garden.

Its propagation is by seed, and by parting the roots. Sow the seed in autumn or spring, in a bed or border, and rake them in; and in June, when the plants are two or three inches high, prick them out in beds to remain till autumn; then transplant them where they are to remain.

By parting the Roots.—In autumn or spring divide the roots into slips or off-sets, and plant them where they are to flower.

HIPPOPHAE, Sea Buckthorn.

Of this genus there are two hardy deciduous shrubs for the shrubbery, adorned with spear-shaped and oval entire leaves, and male and female apetalous flowers.

Class and order, *Dioecia Tetandria*.

Characters] CALIX, male and female flowers on different plants, having monophyllous two-parted cups. COROLLA, none. STAMINA, four short filaments, and oblong angular

H O E

angular antheræ. **PISTILLUM**, a roundish germen, short style, and thick erect stigma. **PERICARPIUM**, a globular unilocular berry, and one seed.

The species are ;

¹**HIPPOPHAE** *Rhamnoides*.

Rhamnoides, or *European Willow-leaved Sea-Buckthorn*.] Hippophae with a shrubby stem, branching irregularly eight or ten feet high, having a dark brown bark, and armed with a few thorns ; spear-shaped, long, narrow, sessile leaves, of a dark-green above, and hoary underneath ; and male flowers in small clusters, and females on separate plants, growing singly, succeeded by berries in autumn.

²**HIPPOPHAE** *Canadensis*.

Canada oval-leaved Sea Buckthorn.] Hath a shrubby brown stem branching eight or ten feet high ; oval leaves, and male and female flowers on separate plants.

Both these shrubs are very hardy, the first grows wild on the sea-shores in several parts of England, and the second in America.

They are retained in gardens as furniture for the shrubbery to encrease the variety with their two-coloured leaves, being of a dark green above, and of a hoary white underneath ; and in winter, when devoid of foliage, their young shoots being covered with turgid, irregular, scaly buds, exhibit also a singular variety.

They are cultivated in all the nurseries for sale ; and may be transplanted any time in open weather from October till March.

Both sorts are propagated abundantly by suckers from the root, by layers, and by cuttings of their young shoots. All of which may be performed in autumn, winter, or spring.

HOE, for hoeing ground, &c.

A Hoe is a most useful and well known garden instrument, of which there are two principal sorts : a Drawing-hoe, and a Scuffling-hoe. The former of which is, however, of the most general use.

Drawing-hoe.—This is the most common and useful kind of Hoe for most sorts of hoeing-work : which being fixed with its edge inward, the workman in using it, always draws towards him, and is one of the most useful implements of gardening for many purposes : such as drawing drills for sowing many sorts of seeds and roots ; for loosening the earth about, and moulding up the shanks of plants ; and hoeing down weeds between

H O E

all sorts of plants, that stand distant enough to admit it ; and is the best adapted Hoe for thinning out esculents to proper distances to acquire their proper growth, such as onions, carrots, parsneps, turneps, spinach, &c. by cutting up all the superfluous plants, or such that grow too close, and at the same time cuts up all weeds, as well as loosens the earth effectually about the remaining plants ; which always proves very beneficial culture to all vegetables.

But of the Drawing-hoe kind, there should be three or four different sizes, from six or eight inches width, down to an inch and a half, as described below.

First size.—This is a large Hoe for common use, about six or eight inches by four broad, fixed on a long handle for both hands, and is the proper sort to use for all common hoeing-work ; such as drawing drills for sowing peas, beans, kidney-beans, &c. (see **DRILL SOWING**) and is the most eligible sized Hoe for hoeing between rows of all those kinds of plants, and all others that stand distant enough either in rows, or otherwise, for the hoe to pass between them, both to cut down all weeds and loosen the ground, and to earth up the stems of the plants. It is also the proper sized Hoe for hoeing turneps, especially the general crops of the larger kinds, to thin them out to proper distances, and cut down weeds ; likewise for all other purposes of hoeing where the plants stand distant, both in the kitchen and pleasure-garden : and this is the proper sized Hoe for general use.

Second size.—This should be about four inches broad, and is useful for hoeing among various plants, where the former sort of Hoe cannot be commodiously employed, and to thin such esculent crops that require but moderate distances ; such as the small early Dutch turneps for the first crop ; also for the general crop of carrots, parsneps, spinach, &c. this is also a proper sized Hoe for hoeing flower-beds and borders, where the plants stand close.

Third Size.—This should be two inches and a half, but not more than three inches broad, fixed on a short handle to use with one hand ; and is for the purpose of small-hoeing onions, to cut them out the full distance they require to grow to their proper size. Likewise for early crops of carrots, spinach, &c. and is a very convenient sized Hoe for hoeing between many other young

or

or small plants where a larger Hoe cannot be readily admitted.

Fourth Size.—This should be but an inch and a half broad, fixed on a small short handle for one hand, and is of a proper size for small-hoeing onions the first time, where they stand pretty close, and where it is not designed to thin them out at once to their full distance, but to leave them rather thickish for culling, &c. and will be found very convenient for occasional use among many small crops.

Each of the above sizes of drawing-hoes will be found extremely useful in their turns; and every gardener should furnish himself with a proper set, as the expence is but trifling, and are sold by most of the nurserymen, and at all the ironmongers shops.

Always keep the edges of the Hoes sharp by occasional grinding on a grind-stone, that they may cut clean at every stroke, and the work will be both more easily, effectually, and expeditiously performed.

Scuffling-hoe.—This is commonly called a Dutch Hoe, as being much used in Holland for scuffling their sand-walks, &c. it is fixed with the edge outward, on the end of a long handle, so as the person using it, pushes it from him, and goes backward, never treading on the hoed ground, as with the drawing hoe; and as to size, is from about four to six or eight inches wide, open in the middle, for the mould and weeds to pass through, so as not to be drawn in heaps; having a long socket at the back part, in which to fix the handle, which may be five or six feet long.

This Hoe is very proper for scuffling over any piece of ground to destroy weeds that is clear from crops, or between crops that stand wide, and in which a person may make considerably more expeditious work than with a Drawing-hoe, especially when the weeds are not suffered to grow large; in which case one man can do as much as two. Observing, however, this Hoe is adapted principally for cutting down weeds, or stirring the ground between wide crops, as above noticed; but not proper for hoeing out crops of esculents, nor for earthing up the shanks of plants, nor for hoeing where the plants stand close.

This Hoe for cutting down weeds will also make great riddance in shrubberies and wilderness quarters, where the shrubs stand distant from one another.

It is also one of the best sorts of Hoes for scuffling over sand-walks, or others of loose materials, to destroy weeds, moss, &c.

This kind of hoe will also be found very useful to run over flower borders, to cut up straggling weeds; which, being fixed on a long handle, may be effected by standing in the walks, without treading on the borders.

It may be had at all the nurseries, and at the ironmongers.

HOEING, a necessary garden culture performed by hoe, to destroy weeds, loosen the soil, and to mould up the shanks of plants.

Hoeing is the most expeditious method of destroying weeds between all plants that stand distant enough to admit the hoe between: observing, that all Hoeing designed principally to destroy weeds, should always be performed in dry weather, and the more sunny the better, especially when the weeds are not to be raked off, that they may die as they are cut down, or at least be so much flagged or withered by the sun as not to grow again; cut deep enough to cut the weeds nearly up by the roots, which may be easily effected to all the annuals, or seed-weeds; for if they are only stumped off, they will soon shoot out again; observe also in the course of Hoeing, not to draw the earth and weeds in heaps, as often done, as the weeds, if not raked off, will often grow again; let, therefore, the work of Hoeing be always performed so evenly, that all the weeds be turned upon the surface clear out of the mould; and if any are unavoidably drawn in heaps, or the earth adhere much about the weeds so cut up, always disperse them by a stroke of the Hoe, that all the weeds may be turned fairly above the ground for the sun and air to kill them.

The above work of Hoeing down weeds, is performed either by a Drawing or Scuffling-hoe, as may be convenient, according to the hints given under the article HOE.

But Hoeing, besides its use in expeditiously destroying the weeds, it at the same time, by loosening the surface, disposes the ground to receive the greater benefit from the air, dews, rains, &c. to the great nourishment of all sorts of plants, and by breaking up the surface, dividing the clods, and stirring the earth, keeps it fresh, it proves a very beneficial culture to all vegetables, as will be evident from practice and observation; in every soil; and in soils apt to bind

after much wet, which causes the plants to appear of a stunted growth, apply a Drawing-hoe, cutting deep enough to loosen the ground two or three inches down; it will encourage the plants to put out fresh fibres, add vigour, and greatly promote a free growth.

Likewise Hoeing up earth about the shanks of plants is a very essential piece of culture, such as earthing up rows of peas, beans, kidney beans, cabbages, cauliflowers, &c. which is ever of great service in promoting strength and vigour in the plants.

HOT-BEDS. Beds formed either of horse dung, or tanner's bark, raised two, three, or four feet high, and covered with garden frames, glasses, &c. designed to effect a certain degree of heat, for raising tender plants, and for forwarding others to early perfection.

By the aid of Hot beds we are able, in our northern climate, to imitate that of distant warm countries, so far as to exhibit their plants, flowers, and fruits often in very great perfection, which without such artificial aids of heat, could not possibly be raised, nor continued in these parts of the world; for by the assistance of Hot beds, vast numbers of seeds, which would otherwise remain years in the earth, and some never grow at all, are made to germinate, form plants, continue their growth, and produce their flowers and fruits, as in their native soil. By Hot-beds, also, cuttings and slips of many sorts of trees and shrubs, which would otherwise remain inactive and perish, are made soon to emit fibres at bottom, and shoots at top, and become each a new vegetable.

Likewise by Hot-beds many of our valuable esculents of the kitchen-garden, that succeed in the full ground at one time of the year or other, are brought to perfection a month or two sooner than they would naturally attain in the open air, and some a quarter of a year or more sooner than they could otherwise be obtained, exemplified in the cucumber, which by no art can be made to grow in the full air before May or June, nor be brought to produce fruit in the open ground before July; but by the aid of Hot-beds, are obtained often in the middle of winter, or early in spring: again, asparagus, which grows all the year in the open ground, yet its natural produce never arrives to perfection before May or June; but by hot-beds we obtain it all the winter in any weather, from November until the arrival of the na-

tural crops: peas, beans, kidney beans, radishes, carrots, strawberries, and various salad herbs and other plants, which grow in the open ground, are by Hot-beds forwarded to perfection a month, and sometimes two or three, sooner than they otherwise could be procured.

We also by Hot-beds forward many of our hardy fruits, as cherries, plums, apricots, peaches, grapes, figs, &c. six weeks or two months sooner than they naturally would in the open ground.

By Hot-beds many beautiful and curious annual flowers are raised to perfection, that could scarcely attain to a flowering state here in the full ground, See **ANNUAL PLANTS**.

And by Hot-beds many hardy flowers, both of the herbaceous and shrubby plants, are brought to flower in winter, and early in spring, which do not naturally appear before May and June, such as pinks, carnations, sweet-williams, narcissus, jonquils, hyacinths, tulips, roses, honeysuckles, and various other plants of moderate growth, which you may incline to forward into an early bloom.

Hot-beds, therefore, are of the greatest utility in gardening: they are, as before mentioned, composed of two principal materials, horse-dung and tanners bark; the former of which is the most common sort of Hot-beds for general use, have been already treated of under the articles **BARK-BED**, and **DUNGS**: it will, however, also be proper to give some hints respecting each in this place, under two separate heads, viz. horse-dung Hot-beds, and tanners-bark Hot-beds.

Horse-dung Hot-beds.

As horse-dung Hot-beds are of general utility in gardening, I propose to handle this article at some length, for the benefit of those unacquainted with their nature.

Horse-dung Hot-beds are the most commonly used for all forcing-work in the kitchen-garden, for raising tender or early esculents; also for working forcing-frames, to have early fruits and flowers; for this material, horse-dung, being not only the most easily obtained in all places, but cheaper than Tanners-bark, the other Hot-bed material; besides, that after having performed its office as a Hot-bed, it becomes rotten and buttery, and the most excellent manure that can be for the garden;

H O T

garden; so that horse-dung Hot-beds are preferable for general use in the kitchen-garden. See DUNG.

The sort of horse-dung to be understood for the purpose of Hot-beds, is the dung and wet litter together, daily cleaned out of stables where horses always stand, and are littered down with plenty of straw every night, which being rendered wet by the urine and dung of those animals, composes the principal material for a dung Hot-bed; for the dung alone without litter would do nothing, but the litter being thus moistened, and cleared out along with the dung, are both mixed together, and collected in any considerable quantity in a heap, or formed into a bed, its moisture, by the urine and dung of the horses, which is naturally of a strong hot quality, quickly promotes a fermentation and strong heat, often so violent as not to be able to bear one's hand therein, and even to burn the roots of plants, if any were planted while the vehement heat continues; but by a proper preparation is brought to a moderate degree of warmth, suitable to the growth of vegetables.

Observe also that the dung must be fresh; that is, such as has been but a few weeks in collecting from the stables, or at least that hath not lain so long in the dunghill as to exhaust itself, and greatly lose its heat, and beginning to rot; for the newer the dung the better, its heat proving always the most effectual and durable, provided it is properly prepared, as hereafter directed, previous to its formation into a bed. And although older dung may, by shaking up and mixing coal-ashes therewith, be brought to heat a little again, yet it will be ineffectual, and of short duration, and deceive you; nor should you, if possible, use that very dry stuff, often to be met with, especially that which has heated greatly, burned, and exhausted its fermenting property in the dung-hill, appearing very dry, and of a whitish mouldy colour, for this will never acquire a proper heat; therefore always chuse the fresh, or new-made steamy dung, full of moist litter, which, although ever so long or strawey, if of a moist temperature, by mixing well together in a heap, the whole will acquire a proper fermentation for a Hot-bed; and the fresh dung will be of double the duration of such that have lain long and exhausted its first fermenting property, as above observed, in the dunghill.

H O T

Sometimes coal-ashes are mixed with dung to promote a more quick and durable heat; which, however, is more necessary for dung that has somewhat exhausted itself by being long in the dunghill, when by mixing a bushel or two of ashes to a cart-load of dung, will have some effect in contributing to the strength and duration of the heat; but as to fresh dung full of heat, it requires no such aid, and although it may help to continue the heat longer, yet is apt at first to promote a too fierce burning heat, therefore I would advise it to be used but sparingly in fresh dung.

The dung, previous to its formation into a Hot-bed, should be moved from the dunghill, well mixed, and cast up in a heap, or, if a large quantity, in a long high ridge, to lie a week or two to prepare it to a proper temperature for making the bed; therefore, with a dung-fork, take the long and short stuff as it comes to hand, shaking it up, and mixing it all well together, in a pretty high heap, or ridge; to lie ten, twelve, or fifteen days, or more, as you shall judge proper, according to its quality, for all the parts to be equally moistened and meliorated, and for the strong rank stench and steam to evaporate; and if in six, eight, or ten days, according to the quantity, the whole is turned over, casting it up in a heap again, it will give greater vent to the noxious vapour and burning heat to pass off, and by mixing the parts again, the whole mass will be every way better prepared for the purpose of a Hot-bed: observing that without the above previous preparation of shaking the dung up in a heap, it is apt to heat violently when formed into a bed, so as to burn the earth thereof, as well as the roots of the plants, and send up a strong rank steam, pernicious to all vegetables; and a Hot-bed of this burning quality, is apt to lose its heat suddenly; for all which reasons never omit preparing the dung as above for all kinds of dung Hot-beds.

With respect to the exposure and situation wherein to make the Hot-beds; all Hot-beds should be made principally in the kitchen-garden, in a sunny sheltered situation; and where the ground is rather dry, and free from standing water at all seasons; and it is of much importance to contrive to have the place in a part of the garden nearest the dung, to have as short wheeling as possible, which is an article of great attention where there is a considerable quantity of framing.

As to the preparation of the place for making the Hot-bed; dung Hot-beds are sometimes made entirely on level ground, but most commonly in trenches, a foot or two deep; but for early work, in winter or spring, I should advise to make the bed mostly above ground; that when the heat declines, both sides of the bed may be lined with hot dung quite to the bottom, so as the whole bed, from thence to the top, may have an equal benefit of the lining to revive its decaying heat; which lining is essentially necessary during winter, and in spring until the middle or latter end of May, when the heat of the season renders them unnecessary; whereas when the Hot bed is made in a trench, at an early season, when linings must be added to support a constant regular heat, all that part of the bed within the ground, is consequently deprived of the advantage thereof, unless you shall dig the earth away all round, to the depth of the bed, wide enough to admit of a lining, for as all dung Hot-beds generally begin to decline their heat in three or four weeks, the heat must at any rate be revived or renewed accordingly, during the continuance of cold weather, by an augmentation of fresh hot dung, piled up against the sides, which in practice is called lining the beds; and by applying these linings occasionally, the heat of a dung Hot-bed may be continued four or five months, provided the whole bed from bottom to top can be thus lined: this, therefore, shews the necessity of making these Hot-beds for early work entirely on the surface of the ground; besides, when Hot-beds are made in deep trenches in winter, water is apt to gather in the bottom, and chill the lower part of the beds; I would, therefore, also advise, that in low, or very moist ground, the place where the Hot-bed is to stand, to be rather a little the highest, particularly for early beds, that all moisture from the dung, rains, snow, &c. may drain off. Some, however, are of opinion, that making Hot-beds in a deep trench, preserves the heat longer; this in particular cases as mentioned below, may have some effect, but is not proper at all where lining is necessary; therefore for early work, be persuaded always to make the beds mostly on level ground.

If it is, however, intended to adhere to the old method of making the Hot-bed in a trench, make the trench five feet wide, if for frames and lights; if for hand-glasses, or

paper frames, three or four; and if in winter, not more than a foot deep; and if wet ground, half that depth is full enough, for the reasons before assigned: but if towards summer, the trench may be made a foot and a half deep, that is, for Hot-beds in May, when the ground will be dry, the weather becoming settled, and no danger to be apprehended from copious standing moisture, and the warm season nearly arrived, when but little aid of lining will be requisite, may then with propriety be made in trenches, eighteen or twenty inches deep, as directed for the hand and bell-glass cucumbers and melons: and the whole bed thus made may be earthed all over so closely, as to cover every part of the dung, to confine the heat, that it may retain a due temperature without lining at all, till the middle or latter end of June, when the warm settled weather will be arrived, and the natural temperature of the season will enable the plants commonly raised in these kind of Hot-beds, to succeed without any farther aid of artificial heat, the remainder of the summer.

As to the dimensions of dung Hot-beds they should generally be a parallelogram, or long square, ranging nearly east and west to any length convenient; about four feet and a half or five feet broad, if to be covered with common garden-frames; and three and a half or four feet, if for hand-glasses; raising them, if in winter, or early in spring, three or four feet high, allowing for settling, as they will settle a foot or more in a fortnight's time after making: and the early beds ought to be substantial, otherwise they will not support a due uniform temperature of heat for the growth of plants at an early season, which by aid of linings must be effected till the arrival of warm weather; observing however that Hot-beds made in winter should be three feet and a half high at least when first made, or if four the better. Those made in March need not be above a yard high, in April two feet and a half, and in May two feet may be a sufficient thickness, and even eighteen inches about the latter end of that month; remarking as above-said, that all Hot-beds are to be ranged lengthwise east and west, or nearly so; but more especially those intended to be covered with frames, that they may exactly front the south for receiving all possible benefit of the sun. And as to the method of making the beds, see *Making the Hot-bed*.

Observe

Observe also, that all dung Hot-beds must be moulded or earthed at top, for the reception of seed and plants, covering every part of the dung at top that no steam may rise therefrom without first passing through a body of earth, which otherwise, being of a rank pernicious nature, would prove destructive to most vegetables. Likewise, if the seed or plants are to be in pots, the bed must also be earthed at top, of due thickness in which to plunge the pots to their rims; remarking, that the proper depth of mould necessary to lay upon these Hot-beds is from about five or six to ten or fifteen inches, according to the use or nature of the plants to be raised therein, which is generally noticed in the respective articles; though from about five to eight or ten inches is the most common necessary depths of earth for dung Hot-beds. See *Earthing the bed*, below.

A Hot-bed may be made either for a one-light, two-light, or three-light frame, or for two, three, or more three-light frames in a range; the three-light frames being the most common sorts for general use, especially to receive plants from the smaller frames, to remain to grow to perfection, or to any considerable size. See *FRAMES*. But a Hot-bed designed chiefly as a seed-bed for raising a few plants for transplantation, as cucumbers, melons, tender annuals, &c. a bed for a single frame, either a one-light or a two-light box, may be sufficient, especially for private use, or for early work, or may be for a three-light frame, according to the quantity of plants required. And as the tender plants raised in either of these frames advance in size, fresh Hot-beds of greater extent for two or three-light frames must be made for their reception, according to the directions given under the respective articles requiring the aid of Hot-beds: observing that all dung Hot-beds made in winter, or any time in spring, before the middle of April or beginning of May, should generally be covered with frames and lights, especially for tender plants. But Hot-beds made late, i. e. from about the middle or latter end of April until the end of May, will succeed for several sorts of plants, to be covered with hand or bell-glasses, also with oiled paper frames, as cucumbers and melons for latter crops, and for raising many sorts of annual flower-plants that require forwarding in moderate Hot-beds. And late Hot-beds, for forwarding any of the more hardier sorts of seeds, plants, and cuttings, in default of

frames, or hand-glasses, &c. may be arched over with hoops, and covered occasionally in bad weather and every night with mats until June; or you may contrive very cheap and eligible covers with oiled paper for these late Hot-beds, which are greatly preferable to mats, but under either of which may be raised many of the hardier annuals, as African and French marigolds, chrysanthemum, China aster, ten-week stocks, &c. also strike cuttings of many sorts of plants; but for striking many sorts of the hardier cuttings that require aid of Hot-beds, oiled paper frames are the best covers that can be used for that purpose in May, June, and July; as they at the same time afford both shelter from cold, and shade from the sun, yet admit its influence both as to light and heat in a proper degree for the work of vegetation.

According therefore to the above hints of dimensions, &c. stake out on the ground the width and length of the intended Hot-bed, allowing, if for frames, for it to be two or three inches wider on each side than the frame; and according to that standard may either make the bed entirely on the surface, or in a trench agreeable to the rules before laid down.

Making the Hot-bed.

To make the Hot-bed, shake some of the longest, or most strawey dung along the bottom, to lay the first formation of the bed; then take it long and short together as it comes to hand, and shake it evenly on every part, raising the sides perfectly upright, straight, and as firm as possible, forming the corners also always full and very firm, keeping the middle well filled with the best dung; and as you go on, beat each layer of dung evenly and firmly down with the dung-fork; or, if very long dung, it may be trodden, to settle every part equally. In this manner proceed till the bed is arrived to its designed, or necessary height, according to the season, as before observed, or use it is intended for, as is always hinted in the respective articles, making proper allowance of a foot, or thereabouts, for settling; raising that intended for frames, two or three inches higher in the back or north side than in front, to give the greater slope of the glasses to the sun, finishing the top even in every part; and when the bed is thus raised to the height intended, trim up all the short dung remaining at last round the bed, laying it on the top ridge-ways along the middle, which may either then,

H O T

then, or rather, if a strong bed, in a few days after, when the bed has settled a little, be levelled to make good all inequalities, and smooth the surface; then set on the frames, &c. and earth the bed agreeable to the rules hereafter laid down.

The proper frames and glasses in general use for these Hot-beds, are described under the article FRAMES. The common sorts are one-light, two-light, and three-light frames; the two former generally for smaller purposes, as seed beds, or nursery beds, for raising and forwarding plants for final transplantation into three-light frames; so that one or two of each of these sizes may be sufficient, and have a proper supply of the three-light frames for general use, as before observed. See FRAMES.

Hand-glasses for covering late Hot-beds are of two sorts; squares, or leaded hand-glasses, and bell glasses. The square glasses being four-square, framed with lead, and many panes of glass, the glass being worked into the lead-work, are made by the glaziers, at from two to three shillings and six pence each, according to their size, strength, and goodness of the glass. The bell-glasses are shaped like a bell, all of one piece, are blown at the glass-houses, where they are sold, from ten to fifteen pounds a hundred, or two or three shillings a-piece, and are rather preferable to the square glasses for the growth and preservation of plants, only there is this advantage in the squares, that if broke they can be readily mended; but the bells, when broken, are generally rendered useless, though if not broke into pieces, they may sometimes be joined by a cement of white-lead colour; and the London gardeners, some of which work two or three thousand hand-glasses in a season, generally prefer the bells to the other sorts. Either of these sorts of glasses are proper to use for Hot-beds any time from about the middle or latter end of April to the beginning or middle of June.

Paper frames being light open frame-work, constructed like the roof of a house, or top of a covered waggon, and covered with oiled paper, are most excellent for summer Hot-bed work, i. e. Hot-beds made in May and beginning of June. See CUCUMBER and PAPER FRAMES.

Having, however, formed the Hot-bed for either of the above covers, if it is pretty substantial, particularly those for frames, it will not be proper neither to frame it for

H O T

good, nor earth it, for several days, until a little settled, and the first violent heat subsided; for the heat will be very strong and frequently of a burning quality for the first week or two after it is made: it may, however, be proper to set the frames and glasses on both, to defend the bed from excessive rains or snow, and to draw up the heat sooner, to forward the bed to a proper temperature for the reception of the mould and seeds, or plants, observing to tilt the upper ends of the lights a hand's breadth high, or shove them so much down in dry weather, that the great steam always arising in Dung Hot-beds may pass freely off; for in strong Hot-beds neither the earth, seed, or plants should be put in till the fierce heat and violent steam has a little abated, which may be in six, eight, or ten days, or a fortnight, according to the substance of the Hot-bed, for that for one frame only, will sooner work itself to a proper degree of heat for the purpose of vegetation, than a range for two or more frames, though a Hot bed of slender substance may be framed, &c. earthed and all, as soon as it is made, as no great danger is to be apprehended from burning, and more particularly those for small frames, hand-glasses, &c. but to Hot-beds of any considerable substance, either for one or more large frames, always use the above precaution previous to earthing, sowing, or planting, especially if you intend to sow or plant in the earth of the bed; or even if you sow or plant in pots, plunging them in the earth, that although they may be raised up, if there is danger of burning at bottom, yet but few plants thrive well when there is a very great steam and vehement heat.

Where there are a considerable range of substantial Hot-beds for many frames, the placing the frames thereon before they are to be fixed for good, may not be convenient; in which case it is proper, in default of the frames, to have mats, or dry long litter ready to cover the top, in case of excessive rains, or snow falling, which might chill and retard the bed greatly from becoming of a due temperature for the reception of the earth, &c. and sometimes occasions a bed to become of a burning quality, which otherwise would be of a regular temperature.

In strong Hot-beds designed for strength and duration of heat, it will, as soon as they are made, be proper to provide some sharp-pointed sticks, two feet long, to thrust down into the middle of the bed in different parts, that

that by pulling out the sticks daily, and feeling their lower parts, will enable you to judge of the working and temperature of the bed, to know more readily when of a proper state for the reception of the mould and plants, which in strong beds must not be trusted therein till the burning heat is past.

If the Hot-bed is, therefore, of good substance, and for the large frames, it is proper to let it remain some days to settle, before it is framed for good, because, notwithstanding all the care in making, it will often settle unequally, and should be levelled before it is earthed; in from about three to five, six, or eight days, according to the nature of the dung, or substance of the bed, it will have so far settled as to discover the inequalities, if any; when, if the frames and glasses were placed thereon, for the purposes above mentioned, they must be taken off, and all the inequalities made even by levelling the top as you shall see necessary, making the surface firm, and smooth it off neatly with the back of the spade, and directly put on the frame, &c. for good; then, as a preservative against burning the earth by the violent heat of the bed, some fresh neat's dung, if it can be conveniently procured, may be spread upon the top of the bed, particularly along the middle part, an inch thick or more, especially in strong Hot-beds, under frames for ridging-out cucumbers and melons, plastering it under the middle of each light, where each hill of plants is to stand, in circular patches, about eighteen inches or two feet diameter, as directed in the article CUCUMIS, for cucumber and melon Hot-beds: this done, put on the lights, tilting them at top to give vent to the steam, as before observed; and as soon as the bed is become of a moderate temperature, and there is no danger from too violent a heat, put on the earth, to receive the seed or plants.

With respect to earthing the bed; observe that substantial dung Hot-beds for frames, after being covered with the frames, &c. they sometimes heat violently the first week or fortnight; and that if the earth was put in during the fierce heat, it, by confining the heat and steam still more closely, will be in danger of being burnt to a whitish mouldy colour; and burn also the roots of the plants, if any were sown or planted; and when the earth is thus burnt by the heat of the dung, no seeds nor plants can vegetate or thrive in it; so that when this happens to be the case, all the earth must be taken out, and replaced

with the like quantity of fresh compost. Therefore, in Hot-beds of any considerable substance, either for one or more frames, examine, previous to moulding it, its state of heat daily with good attention, both by the sticks, and by thrusting your hand down into the dung: thus you will judge regularly of the working of the bed from its first formation, to its greatest heat; and thence till the vehemence of it begins to abate, and become proper for vegetation; then prepare to put in the mould. It is an observation worth notice, that when a sort of *fungi*, or spawn of the mushroom tribe, which often rise in dung Hot-beds, begins first to appear, is a certain sign that the Hot-bed, if ever so strong, is in a proper temperature both for the reception of earth, and plants.

But, as we formerly noticed, slender Hot-beds, made but about eighteen or twenty inches depth in dung, seldom require so much precaution as above, which is directed chiefly for strong beds, made from about two to three or four feet high, for large frames, to shew what is often absolutely necessary to be done, for the benefit of the plants to be cultivated in them: therefore as to slender Hot-beds, as their heat is never so violent nor durable, may, according to their substance, either be earthed as soon as made, or in two, three, or four days after, as you shall judge proper by the above rules, which is most commonly mentioned in the different articles.

Observe, however, even in the strongest Hot-beds, to watch the opportunity of its proper temperature; not to lose any time, for it to waste its heat ineffectually, without being earthed, sowed, or planted.

The earth for all sorts of Hot-beds, should be rich and light, and of a dry temperament; but more particularly for early work in winter and spring, especially for tender plants, such as cucumbers, melons, tender annuals, &c. for very moist earth rots such tender plants while young, binds too close, and by its compactness confines the heat and steam, so as to burn at bottom, and scorch the roots of the plants; let, therefore, some mould be always ready, drying in some airy shed, two or three weeks before-hand, for early work. See COMPOSTS.

The depth of earth necessary to be laid on these Hot-beds, is according to the purposes for which the Hot-bed is designed, whether principally for sowing seed, or for the reception of plants, and according to the nature of the

plants, or whether designed chiefly for plunging pots; but generally from about five or six, to ten or twelve inches, is the common depth; observing if for sowing seeds to raise plants for transplantation, the depth of mould to be from about four to six inches, and if the plants are to remain where raised, to acquire their full growth, not less than from about six or eight to ten or twelve inches depth of earth, will be requisite; and if for the immediate reception of plants, to remain, or for striking cuttings of any sort, &c. from about six to eight, ten, or twelve inches of mould will also be necessary, according to the size or growth of the plants; for those which naturally have large tops, either spreading like cucumbers, &c. or upright growers, must have depth enough of mould for their fibres to draw proper nourishment to support their stalks and branches; as for example, cucumbers and melons being very branchy spreading plants, producing large fruit, consequently require more substance of earth than small salad herbs, and so in proportion to other plants that are to grow to perfection in the Hot-bed: and if for plunging pots, containing either seed or plants, several inches of earth is necessary, according to the size of the pots, in which to plunge them, without going into the dung of the bed; therefore, according to these hints, you will readily judge of the proper depth of the earth generally necessary upon dung Hot-beds; other particulars are exhibited under the respective articles.

In earthing the beds, be careful to cover every part of the dung within the frame therewith, especially after the plants are come up, or any planted, that no steam may rise immediately from the dung upon them, for the steam of horse-dung being of a very rank cutting nature, as is evident by its effect upon one's eyes, that if it attacked the plants, without first passing through a body of earth, would destroy most sorts it encounters in its passage from the dung; which is called steaming the plants.

With regard to sowing or planting seeds or plants in the above Hot-beds, observe as directed for moulding the bed, that if the bed is of strong substance, and under frames, be careful neither to sow nor plant till the danger of burning is over, especially not unless the sowing or planting is performed in pots, that may be moved up as occasion requires; but at any rate it is always better to wait a day or two, than to endanger burning good

plants: do not, however, lose time when the bed is ready, for it is necessary always to have a lively heat at first to promote a quick germination in the seeds, or to strike and set the plants a-going, so as to assume a free growth at first setting off; so that in slender or very moderate Hot-beds, the seeds and plants may be committed to the earth as soon almost as it has acquired a little heat.

And as to the method of sowing the various seeds and plants commonly raised in these Hot-beds, it being different according to the sorts, so is generally exhibited under each respective article.

In respect to the management of the Hot-beds after being sowed or planted with seeds or plants, it is often different, according as the different plants may require, but take the following general hints: the seed or plants being put in, the glasses are to be continued constantly on until June or July, when the weather is become settled and warm, particularly to all the tender kinds of plants; fresh air, however, must be admitted daily, at all opportunities in mild weather, by tilting the upper ends of the lights, or, if hand glasses, by propping up one side, from about half an inch to three or four high, according to the heat and steam in the bed, and temperature of the outward air; shutting all close in due time towards evening, and must be kept close every night during the cold weather; cover also the glasses every night with mats until June, especially for the more tender sorts of plants; one or two mats thick may be sufficient covering while the bed is in full heat; but when it decreases, you may augment the covering by the addition of another mat; never suffering the mats to hang down low over the sides of the frame and bed as is often practised intentionally to keep out the cold more effectually; but this not only excludes the free air too much, to the great detriment of the plants, by drawing them up weak, and of a sickly yellow colour; it also promotes a rank steam, pernicious also to the health of all vegetables, and often proves the death of many of the more tender herbaceous tribe.

When the first great heat of the bed is abated, which may be in a week or fortnight after it is made, if in winter or early in spring, when cutting winds, or driving cold rains and snow may be expected, it is good culture to lay a quantity of dry long litter, either straw, waste hay, or fern, round the sides of the bed, quite from
the

the bottom, half a foot or more thick, and as high up the frame as the earth within side reaches: it will greatly preserve the heat in a proper temperature, and the bed will not require to be lined so soon as it otherwise would do.

But when the heat of the bed naturally declines, or becomes of a weakly temperature, it must be renewed by adding fresh hot dung around the sides, which is called lining the bed, and is particularly necessary for all dung Hot-beds, made any time in winter or spring, until the beginning or middle of May, that are designed to continue plants any considerable time; but those Hot-beds made in May generally support a due degree of heat without lining, until the arrival of warm settled weather, as before observed. With respect, however, to linings to early beds, they may sometimes require a repetition of new linings three or four times, especially those made in winter, to continue them in a uniform heat; these linings should be of the hottest dung, and applied quite from the bottom to the top of the bed, and about eighteen inches wide at bottom, drawing it in to about a foot wide at top, raising it four or five inches up the frame, to allow for settling, but not more, for the top of the linings, when settled, should be but very little above the bottom of the frame, lest its heat burn the earth adjoining to the frame within side: and to prevent steam from rising too copiously from the linings, lay a stratum of earth on the top, two inches thick, continuing it close up to the bottom of the frame, that no steam may arise that way, for the rank steam immediately from dung, without first passing through a body of earth, is destructive to most plants; according as the lining settles down lower than the top of the bed, add more fresh dung, observing the precautions as above; and when the heat of the lining is exhausted, it must be renewed with a fresh quantity of dung, or some of the best of the former lining may be shaken up and mixed with a good quantity of new, and worked up in a lining, as before directed; in this manner we must continue to support the heat of dung Hot-beds as long as the aid of artificial heat is requisite for the growth of plants contained therein. See LINING.

For Tanner's-bark Hot-bed, see BARK-BED, where it is fully explained.

HURA, Sand-box tree.

It is an exotic tree of South-America, kept here in our hot-houses for variety, and for

the beauty of its ample cordated foliage; producing monoecious flowers, succeeded by large swollen capsules in America, where the natives use them for sand-boxes, for writing desks: whence it derived the appellation Sand-box tree.

Class and order, *Monoecia Monadelphia*.

Characters.] CALIX, male and female flowers apart on the same plant, the males in an oval amentum, each floret having a small two-leaved cup, which in the female is monophyllous and swelling. COROLLA, none. STAMINA, one filament, and a double series of antheræ. PISTILLUM, a roundish germen in the bottom of the calix, a very long cylindrical style, and large funnel-shaped stigma, divided into ten equal segments. PERICARPIUM, a globular, ligneous, twelve-furrowed fruit, of twelve cells, and so many seeds, bursting open at top with an elastic force and great noise.

The species is;

HURA *Crepitans*.

Explosion-tree, or American Hura, commonly called Sand box-tree.] Hath an upright, soft, ligneous stem, dividing into a branchy head, rising twenty feet high, adorned with large heart-shaped leaves, eight or ten inches long, and near as broad, on long foot-stalks; and monoecious, apetalous flowers, the males in oval amentums, the females separate, having each a very long style, and large funnel-shaped stigma, divided at the brim into ten segments, appearing like petals, succeeded by a large round, compressed, woody capsule, with twelve deep furrows, and so many internal cells, and the like number of seeds, which when ripe, the capsules burst with an elastic force and explosion, sometimes equal to that of a pistol, discharging the seeds to a considerable distance.

The whole plant abounds with a milky juice, and the stalk and branches are somewhat succulent.

This beautiful and curious exotic being a native of the hottest regions, in this country must always be kept in the hot-house; potting it, therefore, in pots of rich light earth, and plunge them into the bark-bed, where the plants will attain twelve or fifteen feet stature, and frequently produce flowers; watering it sparingly in winter.

Its propagation is by seed; these are procured from abroad by the importers of seeds, generally arriving in the spring, which should be sowed as soon as possible in pots of rich earth, and plunged in a bark hot-bed; when

H O T

plants, or whether designed chiefly for plunging pots; but generally from about five or six, to ten or twelve inches, is the common depth; observing if for sowing seeds to raise plants for transplantation, the depth of mould to be from about four to six inches, and if the plants are to remain where raised, to acquire their full growth, not less than from about six or eight to ten or twelve inches depth of earth, will be requisite; and if for the immediate reception of plants, to remain, or for striking cuttings of any sort, &c. from about six to eight, ten, or twelve inches of mould will also be necessary, according to the size or growth of the plants; for those which naturally have large tops, either spreading like cucumbers, &c. or upright growers, must have depth enough of mould for their fibres to draw proper nourishment to support their stalks and branches; as for example, cucumbers and melons being very branchy spreading plants, producing large fruit, consequently require more substance of earth than small salad herbs, and so in proportion to other plants that are to grow to perfection in the Hot-bed: and if for plunging pots, containing either seed or plants, several inches of earth is necessary, according to the size of the pots, in which to plunge them, without going into the dung of the bed; therefore, according to these hints, you will readily judge of the proper depth of the earth generally necessary upon dung Hot-beds; other particulars are exhibited under the respective articles.

PERICARPIUM, a globular, ligneous, twelve-furrowed fruit, of twelve cells, and so many seeds, bursting open at top with an elastic force and great noise.

The species is;

HURA *Crepitans*.

Explosion-tree, or American Hura, commonly called Sand box-tree.] Hath an upright, soft, ligneous stem, dividing into a branchy head, rising twenty feet high, adorned with large heart-shaped leaves, eight or ten inches long, and near as broad, on long foot-stalks; and monoecious, apetalous flowers, the males in oval amentums, the females separate, having each a very long style, and large funnel-shaped stigma, divided at the brim into ten segments, appearing like petals, succeeded by a large round, compressed, woody capsule, with twelve deep furrows, and so many internal cells, and the like number of seeds, which when ripe, the capsules burst with an elastic force and explosion, sometimes equal to that of a pistol, discharging the seeds to a considerable distance.

The whole plant abounds with a milky juice, and the stalk and branches are somewhat succulent.

This beautiful and curious exotic being a native of the hottest regions, in this country must always be kept in the hot-house; potting it, therefore, in pots of rich light earth, and plunge them into the bark-bed, where the plants will attain twelve or fifteen feet stature, and frequently produce flowers; watering it sparingly in winter.

Its propagation is by seed; these are procured from abroad by the importers of seeds, generally arriving in the spring, which should be sowed as soon as possible in pots of rich earth, and plunged in a bark hot-bed; when

the plants are come up about three or four inches high, plant them out into separate small pots, giving water, and plunge them also into the tan-bed, or into that in the stove, retaining them always there, shifting them into larger pots occasionally. See STOVE PLANTS.

HUMULUS, the Hop-plant.

One species only constitute this genus; a hardy climbing perennial, producing annual stalks, twining round any support to a great height, terminated by scaly clusters of flowers and fruit, of admirable value to the brewers, in procuring an agreeable bitter to beer, rendering it more wholesome, and keeping it from souring.

Class and order, *Diœcia Pentandria*.

Characters.] **CALIX**, male and female flowers on different plants; the males having a five leaved cup, and the females a quadrid, acute, general involucre, and the partial one four-leaved, and contains eight florets, each furnished with a monophyllous perianthium. **COROLLA**, no petals. **STAMINA**, five capillary filaments in the males, and oblong antheræ. **PISTILLUM**, a small germen, two awl-shaped, reflexed, spreading styles, and acute stigmas. **PERICARPIUM**, none. **SE-MEN**, a roundish seed succeeds each female floret, lodged in the base of the calix.

There is but one species, which admits of two varieties; the male hop—and female hop.

The species is;

HUMULUS *Lupulus*.

Humulus, or Hop-plant, formerly, *Lupulus*.]

Hath a long, slender, fibrey, perennial root, sending up annually several climbing, long, slender, rough, tough, purplish stalks, twining round any support fifteen or twenty feet high; adorned with large palmated rough leaves, on long foot-stalks, and whitish-yellow, apetalous, scaly flowers, in pendulous clusters from the sides and ends of the stalks; appearing in July, and the seed, and scaly covers, which are the Hops, ripen in August and September.

Varieties.] Male Hop-plant, bearing male flowers only, growing in long clusters—female Hop-plant, bearing female flowers only, produced in roundish, scaly, leafy clusters.

The male Hop grows wild in hedges and bank sides, and is never cultivated: its young shoots, however, in spring, prepared like asparagus, affords a palatable food.

The female Hop is the only sort that is

cultivated, and admits of some varieties, by the Hop-planters termed: early white Hop—long white Hop—oval Hop—square garlick Hop, &c. and these varieties of female Hop-plants are the sorts cultivated, to produce that valuable commodity called Hop, well known to all for its excellent properties in improving all sorts of beer and ale.

These plants are rarely cultivated in gardens, except a few, by way of climbers, for variety; for they will twist round poles, or any similar support, twenty feet high or more.

They are very hardy, and will grow any where; observing, however, those intended for use, should have an open sunny exposure, and as good ground as possible; in any open field that produces good grass or corn, prepared for their reception by digging or ploughing; though when large quantities are cultivated for sale, ploughing is the most expeditious and cheapest tillage; and the sets, i. e. cuttings of suckers from the root are planted in rows, six or eight feet asunder in spring, which shoot up the same year into stalk, and produce ripe Hops in autumn; and the roots abiding for years, send up a fresh crop annually.

Propagation and Culture.

Their propagation is by cuttings of the suckers arising immediately from the roots within the ground, every part of which will grow, cutting them six or seven inches long, each having three or four buds, or eyes, for emitting shoots, and are taken from the roots of the plants, of any old plantation in full perfection of bearing; being particular to chuse good sorts, and such that are good bearers, trimming each set from all old vine, and any hollow, or bad part: the spring of the year, at Hop-dressing time, is the proper season for procuring the sets; that is February, March, and beginning of April; they may also be propagated by layers of the young shoots in summer; cutting off their tops at the time of laying, they will root and form sets for next spring.

It is of consequence to be choice in the sort of Hop to plant; they should be all of a sort, not early, middle, and late kinds planted together, which by ripening at different times, would occasion great trouble in gathering.

The early white Hop comes first, is a fine Hop, but an indifferent bearer. The long white Hop is next, is a good bearer, and valuable

H U M

luable sort. The square garlick-hop is latest, is a plentiful bearer, but a coarser Hop than the former.

March and April is the proper time for planting them.

The ground should be well digged, or else deeply ploughed, and well rough-harrowed, to break all clods, and render the surface fine and smooth; and if the ground is rather poor, some well-rotted dung, or a compost of dung and earth together, may be laid in heaps to mix in each hole.

Then having the sets ready, proceed to plant them by line, in straight rows, six or eight feet distance, and the same distance in each row, in the quincunx order. Be provided with a long line, to reach quite across the ground, and in which, at every six or eight feet, tie a knot, or small bit of rag; then stretching the line, and having a quantity of small sharp-pointed sticks, place one down at each of the marks, and in each place a hole is to be digged, a foot and a half wide, and filled up again with the earth and rotten dung, for the reception of the plants, four or five in each, as directed below; having thus marked out one line, remove it six or eight feet farther, placing it so as the marks thereon may be opposite the middle of the spaces or intervals of the first row, that the plants may stand in the quincunx form, and place the sticks as before; so on to a third, and every row to the end. But the way to have them in an exact quincunx order, is to have a triangular gage, made with three pieces of pan tile lath, &c. eight feet long, joined together in form of a triangle, making the ends cross each other, about an inch or two in a forked manner; then having placed one row of sticks by line, as above, apply two ends of the triangle to two of the sticks, one stick between each fork, and then plant a stick in the fork of the other end of the gage, to form the next row; thus moving the triangle along, place it to two more sticks in the first row, as before, plant another stick in the fork of the other end, and so proceed to the end of the row, and in the same manner set out every row till the whole is completed; thus you form an exact quincunx, and the plants will also range exactly every way, and appear very beautiful when they are poled.

Then, where each stick stands, dig a round hole about eighteen inches wide, and a moderate spade deep, breaking the earth well, casting some out, and add to the rest some of

H U M

the rotten dung or compost from the heaps laid for that purpose, mixing it well with the earth of the holes, forming it in a sort of hillock in each hole; tho' where the soil is fresh and naturally good, there will be no absolute necessity for dung; so may only dig the holes to loosen the earth well, at the same time drawing some of the top mould on each side round the hole in a small hillock, the width of the hole, and two or three inches high, levelling the top, and hollow it a little; the places thus prepared in either of the above methods, are ready for the plants.

The plants, or sets, are then to be planted four or five in each hill, with a dibble, one in the middle, and the rest round it, at four inches distance, and all nearly even with the general surface, pressing the earth close about them, and cover them over with finely-broken mould as you go on, and this finishes the work.

The plantation being thus formed, the next care is to keep it clean from weeds by hoeing: the first hoeing will be requisite in May, chusing dry weather, and, as you proceed, draw a little mould round about each hill to form a greater body of earth immediately about the plants, continuing the hoeing during the summer as there shall be occasion.

The plants will shoot forth into vine tolerably strong, early the same year; so that in May small poles may be placed to each hill, for them to run upon, as hereafter directed, and they will produce a few hops the same year, though some do not pole them at all the first season, only twist the vine into a bunch in June, at the top of each hill, regardless of any crop, as it is apt to weaken the young plants.

The next necessary work is in spring following to dress or prune the Hops, and February and March is the proper season, when the ground is to be dug or ploughed, and the earth about the hills of plants, be removed away near to the stocks or roots, clearing it quite away from the tops of the principal roots with an iron picker, for the convenience of pruning close to the head of the stock; then with a sharp knife trim off all shoots of last year, or the remaining part of them, close to the head of the stocks or sets; clearing away also all young suckers, and directly trim in the earth around each hill, and cover the top of the stocks with mould two or three inches thick; and this is to be every year repeated.

After

After this the plants will soon shoot forth into vine, or bind, when long poles about fifteen or twenty feet in length, must be placed for them to run upon: April or the beginning of May, when the shoots are a foot long, is the season for this work, three poles must be set to each hill, around the outside, let deep into the ground, by making holes for them with an iron crow, so as to place them with their top inclining a little outward from each other, to keep the plants from entangling, and a space between two of them be left open toward the south, to admit the sun more freely.

The Hops being thus poled, they will for the general part naturally twine themselves about the poles, observing to direct such with the hand as do not readily catch hold of themselves, turning them the way of the sun's motion, and tie them loosely with dried rushes or other soft bandage, training two or three vines to each pole, and all above that should be plucked up, if the plantation be old; but if young, wrap them up together in the middle of the hills.

The next work is summer-digging, in the beginning of June, which is digging about the hills, and casting up some fine earth around, and upon each, which is sometimes repeated again the beginning of July, to make all the hills of a proper substance, for the better nourishing of the plants.

After the plants are grown up, if you find any of them under-poled, taller poles must be placed near those that are too short, to receive the vines from them; for unless they have due length of pole, they will not yield a full crop; and if the vines are very strong, and over-top the poles, it is common to strike off the heads of the shoots with a switch, whereby they throw out many lateral branches, well charged with clusters of fruit.

In July the Hops will blow, and towards the end of August will begin to ripen; the tokens of which are the bunches of fruit imparting a strong Hop-like scent, dry and hard to the touch, and brownish colour of the seed.

At these tokens of maturity the Hops are fit for gathering, when they should be picked with all possible expedition, for a sudden storm of wind, or great rains would do considerable damage, by breaking down the vine and discolouring the Hop.

This work of picking Hops must be performed in dry weather if possible.

A certain number of hills in a square space is to be cleared at a time, generally about eleven, and a large square bin, or wooden frame eight feet long, by three broad, having a cloth within hanging on tenter-hooks, is to be placed in the centre to receive the Hops; then proceeding to the work of picking, cut up the vine of the above number of hills, and pull up the poles, using a wooden instrument like a lever, having at one end a forked piece of iron with teeth on the inside, which will readily raise them out of the ground; then laying two poles at a time across the bin, and two or three persons may stand on each side to pick the Hops therein, picking them very clean without leaves and stalks; and as the bin is filled, it must be emptied two or three times a day, as there may be occasion, into a hop-bag, and carried to the kiln to dry.

The kiln for drying Hops is the same as a malt-kiln, covered with a hair cloth, on which they spread the hops, which should be spread ten or twelve inches thick; and a charcoal fire is commonly used, continuing an even steady fire, not fierce, but rather increase it by degrees, and in about nine hours let the Hops be turned, and in two or three hours more, they may be taken off, by that time the brittleness of their stalks, and easy falling of the leaves determine them to be sufficiently dried.

They are then to be carried into dry upper rooms, to lie three or four weeks to toughen, otherwise they would become powder in bagging.

The bagging is performed in large bags made of about four ells and a half of ell-wide coarse cloth; about a handful of hops is first tied into each corner at bottom, to serve as handles; the bag is then fastened to a hole of due width in the floor, made for that purpose, having a hoop fastened to the mouth of the bag, on which it rests on the edges of the hole; then a person puts the hops into the bag, while another is continually treading them down, till the bag is full; the bag is then unfastened from the hoop, and let down, and close up the mouth, tying a handful of Hops also in each corner, as in the bottom part, they are then ready for market.

The most considerable plantations of Hops in England, are in Kent and Surry, and some parts of Suffex and Hampshire, but more particularly Kent, where the Hop gardens exhibit a delightful appearance in summer, and
from

from which county it is amazing to see the numbers of great waggon loads daily brought to London in September and October, principally to the Borough of Southwark, where are the great magazines of them for the supply of the brewery; great quantities are also brought by water, and deposited in warehouses in Thames-street, belonging to the hop factors.

A plantation of Hops will continue in good bearing several years, provided the ground is properly manured.

The proper manure is well-rotted dung, or a compost of dung and earth together, prepared some time for that purpose; and of either from about twenty to forty cart load, is the common allowance for an acre; the former quantity is generally allowed when dung is scarce, laying it only along the hills of plants to be dug in, in winter or spring, but the best way is to allow about forty load, and dig or plough it in any time from October till March; and such a dressing need not be repeated but once in two or three years.

Every year after the ground is cleared from the Hops, care should be taken of the poles, which if they could be laid under any covered place, would greatly preserve them; but for want of such convenience, they are placed in parcels upright in the open air, first fixing three or six poles firmly in the ground, in a triangle manner, wide at bottom, and tied together at top; then set as many of the rest of the poles about them as shall seem convenient in each parcel.

As the poles decay, they must be recruited with new ones.

The poles may be of any wood, but the sorts commonly used are ash, birch, maple, sycamore, willow, poplar, and chestnut, the latter of which is the most durable of all.

It requires about three thousand poles to an acre, allowing three to each hill.

HYACINTHUS, Hyacinth, and the *Muscari*, or Musk Hyacinth.

The plants are low, herbaceous, bulbous-rooted, flowery perennials, for the flower-garden and open borders; sending up annually from the root, long narrow leaves, and upright flower-stalks, from about half a foot to twelve or fifteen inches high, terminated by many bell-shaped six-parted flowers, in a large erect spike; some of which are of admirable beauty and elegance, and the florists pride, particularly that celebrated species the

Hyacinthus Orientalis, which comprehends some hundreds of delightful varieties, all beautiful ornaments of the spring.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, none. COROLLA, is monopetalous, bell-shaped, six-parted, and reflexed at top, and three small nectariums like pores, placed on the point of the germen. STAMINA, six short subulate filaments and connivent antheræ. PISTILLUM, a roundish, trigonous, three-furrowed germen, short style, and obtuse stigma. PERICARPIUM, a roundish, trigonous, trilocular capsule, and roundish seeds.

To this genus the botanists have joined the *Muscari*, or Musk and Grape Hyacinth, which before was always considered as a distinct genera. There are in the whole about thirteen species of *Hyacinthus*, and of which the following are those principally retained in the English gardens.

HYACINTHUS Orientalis.

Oriental, or Eastern Hyacinth.] Hyacinthus, with a large, purplish, bulbous root, sending up several narrow erect leaves, eight or ten inches long, amidst them; an upright, robust, succulent flower-stalk, from about ten to fifteen inches high, adorned upward with many large funnel or bell-shaped flowers, swelling at the base, and cut half way into six parts; collected into a large pyramidal spike, of different colours in the varieties; flowering in April and May.

Varieties are.] Oriental Hyacinth, with single white flowers—double white flowers—red single and double flowers—flesh-coloured single and double flowers—blue single and double flowers—purple-blue single and double flowers.

Of each of the above sorts, there are many intermediate varieties, amounting in the whole to some hundreds, differing from one another in some respect or other, as in the shades or tints of each respective colour; the size and position of the pips or florets, their number and mode of arrangement in each spike, the form and size of the spikes, and some other variations; all of which varieties have been obtained from seed, and by which many new ones of the above principal sorts are annually gained; each variety is, by the florists, distinguished either by the name of the place where first raised, or person who raised them, or that of illustrious personages, as the greatest kings, the bravest generals, famous poets, and celebrated

brated ancient historians, the gods, goddesses, and the like; often bestowing such names on them as denote their value: so that in this prodigious multitude now of many hundreds, and new ones annually acquired, to which names are given, according to the fancy of the different propagators, it would be impossible to exhibit any accurate list here of any thing so variable, but the names of the capital varieties most in vogue, are always to be found in most of the eminent seedsmen's catalogues; who alter or make additions according as new sorts occur.

This species of *Hyacinthus* and its varieties possessing a degree of pre-eminence above all the other species of this genus, are the sorts commonly esteemed and cultivated by the florists, and the sorts generally meant and understood, when we speak simply of the *Hyacinth*.

²*HYACINTHUS Non-scriptus.*

Wood Hyacinth, or Hare-bells.] Hath a small bulbous root; narrow leaves, five or six inches long; upright flower-stalks, six or seven inches high; and bell-shaped, six parted blue flowers, revolute at top, ranged all on one side of the stalk, appearing in March and April.

Variety.] With white flowers.

Both the varieties grow wild in our woods and hedges; and are cultivated in many gardens as furniture for wood-walks, wildernesses, &c.

³*HYACINTHUS Cernuus.*

Nodding-flowered Spanish Hyacinth.] Hath a small bulbous root; narrow erect leaves, five or six inches long; an upright flower-stalk, six or seven inches high; bell-shaped red flowers, ranged on one side of the stalk, and the top of the spike nodding or bowing downward; flowering in April.

⁴*HYACINTHUS Amethystinum.*

Amethystine-coloured Hyacinth.] Hath a smallish bulbous root; upright robust flower-stalk, a foot high, terminated by many small bell-shaped flowers, cylindric at the base, and cut at top half into six parts, of a deep amethystine-blue colour; flowering in February and March.

The following are the *Muscari Hyacinths*, distinguished by their corolla being more globular and swollen than the former sorts.

⁵*HYACINTHUS Muscari.*

Muscari, or Musk Hyacinth.] Hath a large oval bulbous root, sending up several narrow, furrowed, thickish leaves, eight or nine inches long, ending in obtuse points; an upright

flower-stalk, half a foot high, adorned with oval, reflexed, faded purple flowers, imparting a strong musky odour.

Varieties.] With purplish flowers below, and yellow at top—and with large yellow flowers.

⁶*HYACINTHUS Comosus.*

Tufted Hyacinthus, commonly called Fair-haired Hyacinth.] Hath a large bulbous root; narrow, sword-shaped leaves, a foot long, diminishing to a sharp point; an upright flower-stalk, about a foot high, adorned with angular cylindric flowers, terminated by a tufted cluster of oval florets, destitute of the generative organs; of different colours in the varieties; flowering in April and May.

Varieties.] Tufted Hyacinth, with purple flowers—with blue flowers—and with white flowers.

⁷*HYACINTHUS Monstrosus.*

Feathered Hyacinth.] *Hyacinthus*, with a large bulbous root, sending up several narrow, plane, smooth leaves, a foot long, ending in obtuse points; upright flower-stalks, a foot and a half high, the upper half garnished with many oval blue flowers, in tufted panicles, having finely cut feathered-like petals, mostly destitute of the parts of fructification, so never produce seeds; appearing in April and May.

⁸*HYACINTHUS Botryoides.*

Grape Hyacinth.] Hath a smallish bulbous root; many narrow, cylindric, canaliculated, erect leaves, half a foot long; an upright stalk, six or eight inches high, adorned with many small globular, closely-placed flowers, in a clustered spike in the manner of a bunch of grapes; of different colours in the varieties; appearing in April.

Varieties.] Grape Hyacinth, with blue flowers—white flowers—and with ash-coloured flowers.

⁹*HYACINTHUS Racemosus.*

Racemous Grape Hyacinth.] Hath a middle-sized bulbous root; sword-shaped loose leaves, six or eight inches long; a flower-stalk six inches high, terminated by many small oval blue-flowers, in a racemose-cluster, closely placed at top; flowering in April.

The flowers of all the sorts, in their characteristic, or single state, consist of one hollow, somewhat bell-shaped petal, cut more or less into six parts at top; but in the double flowers, the petals are multiplied in several series, one within another, as in the double Oriental

Oriental Hyacinth, the flowers of which are considerably the largest and most beautiful of all the species.

All these species of *Hyacinthus*, and their respective varieties, are hardy bulbous rooted perennials, of great duration in root, but annual in leaf and stalk; the leaves arising from the root in spring, and amidst them the flower-stalk; but one generally from each bulb, is naked, or without leaves, and the upper part is terminated by the flowers, commonly in a sort of spike; in some extended wide at bottom, upon their pedicles, diminishing gradually to the top, in a pyramidal form, as obtains in most of the varieties of the Oriental Hyacinth; flowering principally in April and May, succeeded by plenty of ripe seed in June and July; then the leaves and stalks decay, and the roots lose their fibres, and become inactive for a month or six weeks; during which period is the time to lift the roots, as may be necessary in some sorts annually, especially the Oriental kinds, and in others every two or three years, to separate the increased off-sets from the main bulbs, and to transplant them into fresh prepared beds, &c. and being taken up at the above period of rest, may be kept out of ground till autumn, or even until spring on particular occasions; though they flower strongest when planted again the October or November following.

All the nine species and respective varieties are so hardy, as to grow freely in any of the open beds or borders in the full ground; flower and produce seed annually, and most of them increase exceedingly by off-sets of the root.

With respect to their use in gardens, all the species and varieties are proper to be employed as furniture to adorn the open borders and flower-beds; the fine varieties of the Oriental Hyacinth is commonly cultivated in beds by themselves: the common kinds of them, however, along with the other species, may also be planted in assemblage with other hardy bulbous spring flowers, in the common borders; disposing all of them towards the front in patches, three or four roots together in each patch, placing them three or four inches deep; in which mode of disposition they will effect a conspicuous variety in April and May.

Of the Oriental Kinds.

But the Oriental Hyacinth, the chief of the Hyacinth tribe for beauty, elegance, and va-

riety, is by florists commonly deposited in beds by themselves, both for the convenience of viewing them more commodiously, and to have occasional shelter from the rigours of winter, and during the time of their bloom; for although they are hardy enough to succeed without any protection, yet they being rather of a delicate temperature, by allowing them shelter on particular occasions, they are made to blow much larger and fairer, and the bloom continued longer in beauty; and as the fine varieties possess a degree of pre-eminence, and often purchased at a great price, it is certainly most necessary to allow them all possible assistance to blow them in perfection.

They are sold in great variety by all the seed dealers. The prices are from three pence per root, up to five or ten pounds, or more; and some varieties are in such high esteem among florists, that twenty or thirty pounds is sometimes given for a single bulb.

The Dutch sorts are in most esteem; that is, those that are imported annually from Holland, for those people excel all Europe in raising the greatest variety from seed, and also in blowing them in the greatest perfection; owing either to some secret in their mode of culture, or that the nature of their soil is peculiarly adapted to the growth of the bulbs; but let that be as it may, great quantities are annually imported from that country by the dealers, and sold by most of the eminent seedsmen, who have catalogues of the names of the varieties, and their prices annexed, which are various according to their sorts.

As many persons may not have inclination for cultivating the high-rated varieties, there are many of the inferior sorts that produce very pretty flowers, which may be had at moderate prices, and may be cultivated either in beds, or in the open borders, in common with other hardy bulbous-rooted flowers without any protection, and will blow freely, tho' probably not so large and elegant as those fine varieties indulged with the nice management of a professed florist, as hereafter mentioned; yet will exhibit a very beautiful bloom, and make some of the prettiest ornaments of the flower-borders.

Having once obtained some roots of any of the varieties, you may increase your stock annually by off-sets, which they, however, do not yield so freely as some other bulbs, so must make the most of every one that offers; and they all furnish plenty of seed.

every year, by which new varieties may be raised, for all the new sorts are always first obtained by that mode of propagation; and each respective variety so obtained, is afterwards increased by off-sets of the root. The raising them, however, from seed, is tedious in practice, for the seedling bulbs are hardly brought to flower in less than four or five years; but as by this means the stock may be greatly increased, and many new good flowers acquired, it rewards for the toil, in enjoying the pleasure of seeing flowers of one's own raising, and the stock greatly multiplied either for pleasure or profit.

The principal properties that constitute a good Hyacinth of the Oriental kind, is, the stem perfectly upright, of moderate length, and so strong and well proportioned, as to sustain the weight of the florets without bending. The florets should be large, swelling below, expanded above, and numerous, ten or fifteen at least, but are often twenty or thirty in number, and should be placed equally round the stem, the pedicles on which they grow, longer below than above, diminishing gradually in length upward, so as to represent a pyramid, each pedicle so robust as to support the florets without drooping.

Propagation and Culture.

The propagation of all the varieties is by off-sets from the root, like other bulbous-rooted perennials; see BULBUS; and by seed, to obtain new varieties, both of which methods of propagation as hereafter directed. We will first exhibit their general culture.

With respect to the culture of this celebrated species of Hyacinth and varieties; let it be remarked, that they succeed best in a light soil, and will prosper in any common earth of a garden of that temperature, but delight more particularly in sandy ground; allow them, however, as light a soil as your garden possibly affords, in a dry, open, sunny situation, distant from the drip of trees, for these bulbs, if planted in strong, or very moist land are apt to rot in winter, or become diseased; if, therefore, the soil of your flower-borders or beds are of a strong heavy quality, that part designed principally for Hyacinths, may be meliorated by adding light materials, such as any light sandy earth, from the surface of some field, common, or other place, (not out of deep pits) or drift or sea-sand, or any upper sandy soil, or light earthy compost;

and should the soil of the borders, &c. be of a very light, sharp, sandy nature, a portion of light, pliable, loamy earth, and neats dung, or well-rotted dung of old hot-beds, will make a fine compost for the Hyacinth, being previously added long enough for the dung to be converted into mould. After all, if the common earth of the borders is of a moderately light pliable nature, as above observed, and has been occasionally manured with rotten dung, it will suit the common sorts very well without any other preparation than good digging, &c. observing, in either case, to work the ground well one spade deep at least, if the depth of soil admits, raising the bed or border a little above the general level to avoid copious moisture, and rake the surface smooth.

But the florists generally prepare a favourite compost for their rare kinds of Hyacinths, which is principally this: light sandy loam, or any sandy earth from a pastured field or common, the top spit not more than ten or twelve inches deep, of which about one third to one of drift or sea-sand, from the surface, and the same quantity of rotten neats dung; mixing and casting the whole in a heap ridge-ways, in some dry sunny exposure, to lie a year at least, or if two the better. See COMPOSTS. But to the above materials, some add also a quantity of rotten leaves of trees, thoroughly rotten, tanner's bark, or any perfectly rotten earthy wood, or rotten saw-dust; all of which together greatly improves the composition: though as these are not always readily obtained, the other compost is frequently used with great success. With either of these composts a bed is prepared in September, or early in October, four feet wide, and two deep, so that a cavity must be dug that width and depth, and filled up entirely with the composition, six inches above the common level to allow for settling, leaving it a fortnight or a month to settle, and is then ready for the reception of the Hyacinths.

The virtuosi in these plants are careful never to plant the fine sorts two years together in the same bed or earth, for by planting them every year in a fresh bed, or fresh-prepared compost, it greatly improves the size and beauty of the flowers.

The proper season for planting them, is either in October, or first fortnight in November, and those then planted, shoot early in spring, and flower strong at their usual season, April and

and May ; but those planted later in autumn, or are continued out of ground till January and February, for a late bloom, will flower weaker and with inferior beauty ; so that the principal part should always be planted at the time first mentioned.

If it is designed to plant any of the common, or more ordinary kinds, to adorn the open borders contiguous to principal walks, or lawns near the habitation, to increase the variety in assemblage with other bulbous-rooted spring-flowers, as early tulips, narcissuses, anemones, ranunculus, &c. they should be disposed towards the front, at about fifteen inches from the edge, in patches of three roots in each, placed four inches deep ; and the patches may be from about one yard to three or four distance : here let them stand to take their chance, without any further care, and they will flower in their usual season ; and in this mode of disposition will strike the eye most agreeably among the other flowers then in bloom.

But the fine doubles and other valuable varieties are commonly deposited in beds by themselves, as we before observed, for the convenience of affording them occasional protection from inclement weather, these beds should be four feet wide, and well wrought to the depth before mentioned ; and if there is any danger of water standing, or much moisture in winter, raise them five or six inches above the general level ; but if dry ground two or three inches is sufficient, finishing them gradually rounding in the middle, allowing two-feet-wide alleys between bed and bed. In each bed you may plant four or five rows, lengthways, about nine inches distant in each row, and four or five inches deep : as to the mode of planting, it may either be in drills drawn the above depth, see DRILL-SOWING, &c. or by dibble, or by bedding them in, i. e. with the spade or rake, trimming the earth evenly from off the top of the bed, five inches deep, into the alleys ; then draw lines along the surface the above distance, place the roots upon the lines, bottom downwards, nine inches asunder ; which being done, cover the roots over with the earth, which was drawn off the bed for that purpose, as evenly as possible, to the proper depth ; and as soon as they are planted, in either method, let the surface of the bed be raked smooth, and the work is done.

The bulbs being planted, the next care is to protect the choicest sorts in the beds occa-

sionally, during winter, from severe frost, to ensure the greater success ; for although the bulb itself is hardy enough, yet very intense frost is sometimes apt to affect the young new-shot fibres of the root, also the summit of the young advancing flower-bud, and occasion it to blow weaker than it otherwise would ; therefore when severe frost sets in, it is easy to guard those in beds ; but those disposed about the borders in patches, is not so readily sheltered : but, indeed, they will all blow tolerably well without that precaution. Those in beds, however, may be readily protected by a covering of straw, or any kind of dry strawey litter, three or four inches thick, or may previously arch the beds with hoops or rods, or with moveable arched frames of open-work, and covered with mats ; observing in either mode of covering, to practise it only in severe frosts, for there will be but little danger of moderate frosts penetrating deep enough to do any hurt ; nor ever permit the covering to remain a day longer than the severity of the frost continues, the free air being an important article for the welfare of the plants.

Towards spring, when the flower-buds are beginning to appear above ground, the beds of the fine sorts, if intended to allow them all possible protection from inclement weather, should, if not done in winter, be arched over, to be covered every night with mats, particularly at the appearance of sharp frosts, or when there is cold cutting winds, being careful to take them off every morning in mild weather.

In March the flower-stems will advance fast in stature : according as those of the best sorts arrive nearly at their full height, it is proper to support them, by placing a small stick, fifteen or eighteen inches long, down to each plant, being careful not to thrust it into the bulb, and so tie the stems neatly to each stick, whereby the spikes of flowers, which being heavy, would otherwise be borne down by wind or wet, will be preserved in an upright position.

When they arrive to bloom, the curious sorts that are in beds, may be preserved much longer in beauty, by being screened occasionally from the sun and rain, by a sort of awning or umbrella of mats or canvass ; observing they should be shaded only from the mid-day sun from about ten to three or four o'clock, and only from excessive rains and boisterous winds, for they should enjoy the morning

and evening sun, and the benefit of moderate showers; these covers are sometimes contrived like a tent, of width and height enough for company to walk under them to view the flowers, and that the plants may enjoy the benefit of free air; having the sides to let down and up at pleasure, like curtains; as also the top to draw off occasionally to admit moderate warm showers; thus may these flowers be continued in their fullest beauty three or four weeks, and exhibit a fairer bloom than those that are fully exposed.

After the flowers, however, begin naturally to fade, remove all covering entirely away, that the bulbs and increasing off-sets may receive all possible benefit from the free air.

After the season of flowering is over, the next care is to take up the bulbs, in the florists language called, lifting the roots; for the fine sorts should be taken up at this period, both to separate any off-sets for encrease, and for the benefit of the main bulbs, which will always flower stronger than such that are suffered to remain two or more years unremoved; so always take up the large blowing-roots annually after flowering.

The proper time for this work of lifting the bulbs, is in summer, soon after they have done flowering, when their leaves begin to turn yellow, as then the bulbs have had nearly their full growth for that season; and should by no means remain longer in the ground, as they would be apt to imbibe moisture, and become spongy, and have tendency to rot after removal. Dry weather must be chosen, and a trowel, or small spade is proper for lifting them, taking them up one and one; and break off the stem within an inch or two of its origin, which being thick and very succulent, the moisture thereof might return again into the bulb, to its detriment; then lay them in an airy room, out of the mid-day sun, to dry off the gross moisture gradually, and to ripen the bulbs to a due hardness, appearing of a purplish tinge, otherwise they are apt to rot, being more impatient of humidity than almost any other kind of hardy bulbs: but the florists generally ripen the choicer kinds of these bulbs, after lifting, in a ridge of dry earth in the full air, to promote a more perfect ripeness in the whole bulb, as the gross humidity will be more effectually drawn off by the heat of the sun, without being exposed immediately thereto; to do this, part of the earth of the

bed where they grew, is directly formed into a low ridge lengthways, roundish at top, and both sides sloping to cast off the water; in this ridge place the bulbs, as soon as possible, bottom downward beside each other, and cover them with earth an inch or two deep; being thus placed, let them remain about three weeks, during which time, if heavy rains fall, cover the ridge with mats, to keep the earth and roots as dry as possible; and thus the sun's heat through the earth, will evaporate the watery parts of the bulb, and harden it so effectually, that no danger of rotting is much to be feared, neither before nor after they are planted again; observing, that when the bulbs, by either of the above modes of ripening them, assume a bright purple colour, it is notice of matureness, this colour being peculiar to these bulbs, but the more strong and lively the purple tinge appears, denotes the greater perfection.

When the bulbs are, however, properly ripened in either of the above methods, let them be taken up and separated from any off-sets, well cleared from earth, loose skins, and fibres at bottom; then, after exposing them an hour or two in the sun, put them up in boxes singly, or upon dry shelves out of the sun, to remain till the season for planting them again, observing the same method as before directed.

Propagation by Off-sets.—All off-sets appearing about the main bulbs at the lifting season, are to be carefully separated from them, either as soon as they are taken up, or after the bulbs have lain to ripen, kept separate, and planted in September or October, in beds by themselves, in rows six inches asunder, and two or three deep, where let them remain a year or two; then take them up at the proper lifting-season in summer, and manage as directed for the large blowing roots.

Raising them from Seed—The raising these bulbs from seed, is practised by the curious to obtain new varieties, as well as increase their stock; observing, that from the time of sowing, it will be four or five years before the bulbs will produce flowers; the seed ripens in June or July, which may easily be saved from your own plants, suffering some of the finest singles, and half doubles to stand to ripen it in perfection.

The proper season for sowing it is September and October; and will come up in spring following.

It grows freely in the open ground, in a bed or border of light earth, or if no great quantity is to be sown, it may be sowed in pots or boxes, which will be convenient to move occasionally to different situations at different seasons. In either method chuse light rich earth, make the surface smooth, sow the seeds evenly, and cover them an inch or an inch and a half deep; if they are sowed in pots or boxes, let those be plunged to their rims in a dry place, and in November remove them either under a hot-bed frame to have occasional shelter in winter, or cover them at the approach of hard frost with some light dry litter, using the same precaution also to those sowed in beds, but let them be fully exposed in all mild weather.

The plants will come up in the spring, appearing first with very small leaves; keep them very clean from weeds all summer, sift a little earth over the bed in autumn, and in winter use the same precaution as before; and in the second summer, in June, when their leaves begin to decay, take up the young bulbs, to be planted out in nursery beds, which may be done in August or September, planting them in small drills two inches deep, having the drills three or four inches asunder: here let them stand two years, sifting half an inch of earth over the surface in autumn, and give occasional covering in winter: after this they are to be taken up at the usual lifting-season, managed as the other bulbs, and planted in autumn where you design they shall flower.

Of the other eight Species:

The other eight species and varieties of this genus, Hyacinthus, tho' inferior to the oriental kind, yet considered as flowery perennials for embellishing the common borders, &c. they effect an agreeable variety, when disposed in little clusters, in assemblage with other low spring-flowers: planting them in autumn, any time before Christmas, towards the front, three, four, or five roots in a patch, about three inches deep, and they will all flower in spring following. They may be suffered to remain unremoved two or three years, when they will be increased by off-sets into large bunches, and should then be taken up at the decay of the flowers and leaves in summer, to separate the off-sets, planting the large roots again in the borders, as before, in autumn; and the very best of

the off-sets that you may have occasion for, may be planted in nursery-beds for a year or two.

Their propagation is effected plentifully by the off-sets, as above-mentioned, which all the sorts produce in great plenty, and which may be taken up every second or third year, when the leaves decay, and the off-sets separated and managed as above directed.

HYDRANGEA, *Hydrangea*.

There is but one species, a shrubby deciduous plant, three or four feet high, for the shrubbery, having merit for the variety of its large simple foliage, and bunches of quinquepetalous flowers.

Class and order, *Decandria Digynia*.

Characters.] CALIX, is monophyllous, and five-parted at top. COROLLA, five roundish petals. STAMINA, ten filaments, alternately longer than each other, and roundish didymous antheræ. PISTILLUM, a roundish germen under the corolla, two short styles, and obtuse stigmas. PERICARPIUM, a roundish didymous bilocular capsule, crowned by the permanent styles, like two horns, and contains numerous small angular seeds.

The species is;

Hydrangea Arborescens.] Hath a fibrous very spreading root; sending up several shrubby, thick, pithy, perennial stalks, three or four feet high; garnished at each joint with largish, heart-shaped, serrated, opposite leaves, on long foot-stalks; and large cymose bunches of white flowers at the top of the stalks.

It is a native of North America, is very hardy, and flowers here in July and August, but rarely produces good seeds in England.

The propagation of this species is very easy, for its spreading roots sending up many stalks, they may be slipped off with great facility in autumn or spring, with roots to each, and may be planted in the shrubbery to remain, or in nursery rows as may be convenient.

HYPERICUM, St. John's-Wort.

This genera furnishes several hardy deciduous shrubs and undershrubby plants for the shrubbery; and some tender shrubby exotics for the green house; all of them adorned with oblong and oval simple foliage, and pentapetalous yellow flowers in clusters.

Class and order, *Polyadelphia Polyandria*.

Characters.] CALIX, is divided into five oval, permanent segments. COROLLA, five oblong oval spreading petals. STAMINA, numerous

H Y P

numerous filaments, joined in several bodies and small antheræ. *PISTILLUM*, a roundish germen, from one to three or five styles, but most commonly three, and simple stigmas. *PERICARPIUM*, a roundish capsule, of as many cells as there are styles, and numerous oblong seeds.

There are about six or seven species commonly retained in the English gardens as plants of ornament, four of them hardy, and three tender.

Hardy Kinds.

¹*HYPERICUM Hircinum.*

Stinking St. John's-Wort.] *Hypericum* with several shrubby, two-edged stalks from the root, three or four feet high, branching by pairs opposite at every joint; oblong-oval, close-fitting, opposite leaves; and at the ends of all the young shoots, clusters of yellow flowers, having the stamina longer than the petals, and three styles.

The whole plant has a strong disagreeable odour.

Varieties.] *Stinking St. John's wort*, with strong stalks, six or eight feet high, broad leaves, and large flowers—inodorous *St. John's-wort*, with strong stalks, broad leaves, and without any disagreeable odour—with variegated leaves.

All these varieties are shrubby, flower in June and July, in such numerous clusters, that the shrubs appear covered with them, and produce abundance of seed in autumn.

²*HYPERICUM Canariensis.*

Canary St. John's-Wort.] Hath shrubby stalks, dividing and branching six or seven feet high, oblong, close-fitting leaves, by pairs; and at the ends of the branches, clusters of yellow flowers, having the stamina longer than the corolla, and three styles; flowering in June and July.

³*HYPERICUM Ascyron.*

Ascyron, or Dwarf American St. John's-Wort.] Hath very spreading roots, sending up numerous, slender, four-square stalks, a foot long; oval, spear-shaped, close-fitting, smooth leaves, by pairs opposite; and at the ends of the stalks, large yellow flowers, having five styles.

⁴*HYPERICUM Androsæmum.*

Androsæmum, commonly called Tutsan, or Park-leaves.] Hath an upright under-shrubby stalk, two feet high, branching by pairs opposite; oval, heart-shaped, close-fitting leaves, by pairs; and from the tops of the

H Y P

stalks, clusters of small yellow flowers, having three styles; and roundish berry-like black capsules; flowers in the end of July and August.

It grows naturally in woods in many parts of England, &c.

Tender Green-house Kinds.

⁵*HYPERICUM Balearicum.*

Balearic warted-leaved Hypericum.] Hath a shrubby stalk, branching two feet high, with reddish scarrified branches; small, oval, waved, close-fitting, semi-amplexicaule leaves, warted underneath, and large yellow flowers, having five styles; flowering great part of the year. Is a native of Majorca.

⁶*HYPERICUM Monogynum.*

Monogynous, or One-styled China Hypericum.] Hath shrubby purplish stalks, about two feet high; oblong, stiff, smooth, close-fitting leaves, of a shining green above, and white underneath, and clusters of small yellow flowers, with coloured cups, and only one style; flowering most part of the year.

⁷*HYPERICUM Lasianthus.*

Lasianthus, or Surinam Hypericum.] Hath shrubby stalks, branching a yard high; spear-shaped serrated leaves, hoary underneath; and from the axillas of the stalks, yellow flowers, having five styles. Is a native of Surinam and Carolina.

The flowers of all these species of *Hypericum* consist each of five oblong oval petals, numerous stamina, and from one to five styles (see the *Characters*); appearing principally in June, July, and August, and some most part of the year, in numerous clusters, mostly from the ends of the branches and young shoots, succeeded by oval capsules, containing plenty of seeds in autumn, especially in the hardy kinds.

All the species demand attention as plants of ornament, having great merit in their flowers, appearing very conspicuous in long succession.

The hardy kinds are good furniture for all the shrubbery compartments, and will grow in any situation and exposure, and in any common soil of a garden, will endure the severest cold, and greatly ornament the shrubbery in summer; more particularly the first and second sorts and varieties, which are more of a shrubby durable growth, than the other two hardy kinds; but all the sorts merit culture to increase the variety. All of which are sold cheap enough at the nurseries, and may

may be easily increased by suckers, by slips of the root, and by seed. See their *Propagation*.

The three tender species being natives of warm countries, must be potted to have shelter in winter in the green-house, and will effect a pretty variety among the other tender exotics.

Propagation, &c. of all the Sorts.

The first two hardy sorts propagate very fast by suckers, from the root, which are sent up plentifully every year; and in autumn or spring may be readily slipped off from the old plants, with roots to each, or the whole plant may be taken up and divided into as many parts as there are suckers and slips with roots, planting the strongest where they are to remain, and the weakest in nursery rows for a year to acquire strength.

They may also be propagated by seeds, sowed in autumn in a bed of common earth, in drills an inch deep; the plants will rise plentifully in spring, and be fit to transplant the spring following.

The other hardy sorts are also easily propagated by slipping the roots in autumn, or early in spring; and may likewise be raised in great plenty by seeds as directed for the two former.

The three tender species are propagated by layers, and by cuttings. The laying is performed in spring on the young shoots, which will be well rooted by the end of summer; then plant each in separate pots. And cuttings of the young shoots may be planted any time from March till June, in pots, and plunged in a hot bed; they will readily emit roots and form plants.

The Monogynous Hypericum may likewise be propagated by slipping the roots in spring.

These sorts may also be raised from seed sowed in spring, in pots, and plunged in a hot-bed, just to bring up the plants.

HYPERICUM Frutex. See *SPIRÆA*, it being a species of that genus.

HYSSOPUS, Hyssop.

The Hyssop of our gardens is a low undershrubby perennial, a fine aromatic, and medicinal plant.

Class and order, *Didynamia Gymnospermia*.

Characters.] *CALIX*, is monophyllous, oblong, five-parted, and permanent. *COLLA*, is monopetalous and ringent, hav-

ing the upper lip plane, roundish, emarginated and erect; the under one trifid, with the middle segment long and acute, and the side ones short and obtuse. *STAMINA*, two long and two short filaments, and simple antheræ. *PISTILLUM*, a four-parted germen, slender style, and bifid stigma. *PERICARPIMUM*, none, four oval seeds lodged in the calix.

There are three distinct species, but not more than one commonly cultivated, viz.

HYSSOPUS Officinalis.

Officinal, or Common Hyssop.] Hath undershrubby, low, bushy stalks, growing a foot and a half high; small spear-shaped, close-fitting, opposite leaves, having several smaller rising from the same joint; and all the stalks and branches terminated by erect, whorled spikes of flowers, of different colours in the varieties.

Varieties.] Common blue-flowered—white-flowered—red-flowered—long spiked with deep blue flowers—curled-leaved—striped-leaved.

All these varieties are undershrubby, having ligneous durable stalks and branches, and all produce numerous small flowers in whorls round the upper part of the stalks for a great length: each flower is of one petal, of the ringent or grinning kind.

They are very hardy plants, of great estimation as aromatics for medical purposes, and the common blue-flowered kind is the sort chiefly used; and which is generally cultivated in the kitchen garden, sometimes in close rows, by way of edgings to beds or borders, clipping them annually to keep them regular and within due compass; see *EDGINGS*: and sometimes are disposed in beds, &c. in rows fifteen or eighteen inches asunder, and the same distance between the plants in each row. The young shoots are the parts proper for use, and may be cut any time when wanted: observing, however, their season of perfection for any general use, is in summer, when they are in flower; at which time the flower-stalks should be cut down for use, and tied in bunches.

But all the varieties may also be employed to adorn the borders, and other parts of the pleasure-garden, disposing them here and there singly to form bushy plants.

Their propagation is by seed, by slips, and by cuttings.

By Seed.—In March or April sow the seed in a bed or border of light earth, and rake it

it in ; and when the plants are come up, thin them, if too close, and when about three or four inches high, plant them out where they are to remain ; or when it is designed to form an edging of them, the seed may be sown at once where the plants are to remain, in small drills, and covered half an inch deep.

By Slips and Cuttings.—In March, April, or May, slip or cut off a quantity of the robust side-shoots, plant them in a shady border, five or six inches apart ; give water as soon as planted, repeat it occasionally, and they will soon strike root, and in autumn may be planted out where they are always to stand.

J.

JASMINUM, Jasmine, or Jessamine-tree.

The plants are of the shrub kind, mostly of somewhat trailing growth, consisting of three hardy deciduous flowering-shrubs for the open ground, and three tender ever-green flowering-shrubs for the green-house, adorned with pinnated and trifoliate leaves, and numerous monopetalous, tubular, five-parted flowers, which, in most of the species, are of admirable fragrance.

Class and order, *Diandria Monogynia*.

Characters.] *CALIX*, is monophyllous, tubulous, five-parted at the brim, and permanent. *COROLLA*, is monopetalous, with a long cylindric tube, and with the limb or upper part divided into five segments. *STAMINA*, two short filaments, and small antheræ. *PISTILLUM*, a roundish germen, slender style, and bifid stigma. *PERICARPIUM*, an oval bilocular berry, and two large oval seeds.

Hardy Deciduous Kinds.

¹JASMINUM Officinale.

Common White Jasmine.] Jasminum, with shrubby, long, slender stalks and branches, rising upon support fifteen or twenty feet high ; pinnated opposite leaves, of about three pair of sharp pointed folioles, terminated by an odd one, running out to a long point, and numerous white flowers from the joints and ends of the branches ; of a very fragrant odour.

Varieties.] With white striped leaves—yellow striped leaves.

All three varieties flower in great profusion most part of the summer ; the flowers are universally white, and remarkable for their great fragrance ; but are never succeeded by fruit in England.

²JASMINUM Fruticans.

Shrubby Yellow Jasmine.] Hath shrubby, angular, trailing stalks and branches, rising upon support eight or ten feet high ; trifoliate and simple alternate leaves ; and yellow flowers from the sides and ends of the young branches, appearing in June ; frequently producing berries of a black colour.

This species is remarkable for sending up many suckers from its roots, often so plentifully as to over-spread the ground, if not taken up annually.

³JASMINUM Humile.

Dwarf Yellow Jasmine.] Hath shrubby firm stalks, and angular branches, of low, somewhat robust, bushy growth ; broad trifoliate and pinnated leaves ; and large yellow flowers in July, sometimes succeeded by berries.

The above three species are natives originally of distant countries ; the first of India, the others of the southern parts of Europe, but are all hardy enough to grow here in the open ground, and have been many years inhabitants of our gardens.

Tender Green-house Kinds.

The following three species are natives of different parts of India, but succeed here with only protection from frost, and will sometimes live in the open air all the year, against

against a warm wall; it is, however, proper always to keep the principal part in pots to move to a green-house in winter.

⁴*JASMINUM Grandiflorum*

Great-flowered Catalonian Jasmine.] Hath a shrubby, firm, upright stem, branching out into a spreading head, from about three to six or eight feet high; pinnated ever-green leaves, of three pair of pointed lobes, terminated by an odd one; and large flowers, of a bluish red without, and white within; flowering from July till November.

Variety.] With semi-double flowers, having two series of petals.

⁵*JASMINUM Azoricum.*

Azorian White Jasmine.] Hath shrubby, long, slender stalks and branches, rising upon support fifteen or twenty feet high; trifoliate, opposite, ever-green leaves; and largish pure white flowers, in loose bunches from the ends of the branches, appearing most part of summer and autumn.

⁶*JASMINUM Odoratissimum.*

Odoriferous, or most Sweet-scented Yellow Indian Jasmine.] Hath a shrubby upright stalk, branching erectly without support six or eight feet high, large trifoliate, shining, alternate, ever-green leaves, having oval lobes, and the middle lobe the largest; and bright yellow flowers in bunches from the ends of the branches; flowering from July till October, and emits a most fragrant odour.

Most of the above species of *Jasminum* have long, slender, declinated branches, producing many very long, weak, green, pithy shoots annually, and from which the flowers are commonly produced.

The flowers of all the sorts consists of one petal, long and tubular below, and divided at top into five spreading segments. See the *Characters*.

Culture of the Hardy Kinds.

The three hardy kinds are proper furniture to adorn the pleasure-garden; but their branches being mostly long, slender, and of declinated growth, require support, especially the *Jasminum Officinalis*, which is most commonly planted against walls and other fences, both for the convenience of training them, and to ornament the places, with their profusion of flowers in summer. But this and the other two hardy kinds, may also be stationed in shrubberies, training them with upright single stems, half a yard or a yard high, to stakes; and as they will branch out each way, by trimming the long strag-

gling shoots occasionally every spring and summer, they may be made to form bushy heads: those planted against fences, should be pruned down low at first, to force out lower lateral shoots, so as to furnish every part from the bottom upward, and every year a due quantity of the strongest shoots in every part are to be trained in, close to the wall, &c. previously shortening them, more or less according to their strength; but always cut low enough to take off the weak straggling soft parts, and nail them in straight, about four inches apart; and as, in summer, numerous shoots are sent forth from all the branches, and that from the upper parts of the smaller shoots, the flowers generally arise; so that at this season the rudest growing shoots may be reduced to a regularity, either by knife or garden-shears; observing, however, not to clip too close, to cut off the parts that produce the flowers; but knife pruning is most eligible, by which you may train the whole always regular at the above distance, like a wall-tree; in summer, cutting out all the most irregular rambling shoots, and train a due quantity of the principal ones close to the wall, to remain till winter or spring pruning; then selecting some of the strongest in different parts to be trained as above hinted; at the same time cutting out all the superabundant and weak shoots, close to the old wood, so as to preserve all the branches distinct at regular distances, in the manner of a wall-tree; being careful always to leave every year some of the strongest young shoots at proper intervals, quite from the bottom to the top, to furnish flowers in every part, and to supply the place of any decayed, or old naked wood, which should be cut away occasionally in the winter or spring pruning, and its place supplied with young shoots.

Culture of the Tender Kinds.

The three tender species requiring shelter of a green-house in winter, must always be kept in pots, to move them in and out occasionally; let them be potted in rich light earth, frequently watered in summer, and about once a week in winter, but always moderately during that season; prune off all decayed wood, at any time when it appears; and shorten, or retrench the rambling shoots as you shall see occasion, to preserve the heads somewhat regular, managing them in other respects as directed for other green-house shrubs. See GREEN-HOUSE PLANTS.

A plant or two of each of these tender species may also be planted against a warm wall, trained thereto, and left to take their chance, with only occasional shelter of mats in frosty weather.

Propagation of all the Sorts.

The three hardy sorts are easily propagated in great plenty by layers and cuttings. Lay a quantity of the strong young shoots in autumn, winter, or spring, trimming their tops, and they will be well rooted by autumn following: at the same seasons cuttings of the strong shoots, in lengths of ten or twelve inches, planted in a shady border, will be rooted and fit to transplant by next autumn. The *Jasminum Fruticum* may also be propagated by suckers, which it sends up in great plenty, and these being taken off will make good plants.

The striped varieties of the first species are also propagated by grafting or budding in stocks of the common kind.

The three tender species may also be increased by layers in March: chusing the young wood, make a slit at a joint in each layer, where they are to be layed, and lay them in the usual way; give plenty of water all summer: they will be properly rooted by autumn, when each layer is to be separated from the parent, and planted singly in pots, and placed among the other green-house exotics.

These three kinds are also very commonly propagated by grafting, and budding them upon the common white, and shrubby yellow Jasmine.

They are also raised from seeds, more particularly the Azorian Jasmine, and *Jasminum Odoratissimum*. Sow the seed in March or April, in pots of light rich earth, an inch deep, and plunge the pots in the earth of a moderate hot-bed under frame and glasses; refresh them with frequent sprinklings of water, and the plants will rise in five or six weeks, or in a little more or less time, when fresh air must be admitted daily, by tilting the lights, giving also frequent waterings; and towards the middle or latter end of May, begin to inure them to the full air, and remove them into it fully in June, to remain till October, then moved into the green-house for the winter; and in March or April following, transplant them into separate small pots, and managed as other green-house shrubs.

JATROPHA, Cassada, or Cassava-plant, &c.

This genus furnishes shrubby, elegant, flowery perennials, natives of the warm parts of America, and retained here in hot-houses for variety; growing with durable stems and branches, erect, from about a yard to eight or ten feet high; adorned with divided palmated leaves; and monoecious, monopetalous hypocrateriforme males, and quinquepetalous female flowers.

Class and order, *Monoecia Monadelphia*.

Characters.] CALIX, monoecious flowers, having a very small cup to the males, and none to the females. COROLLA, is, in the males, monopetalous, hypocrateriforme, five-parted and spreading; and, in the females, consists of five rose like petals. STAMINA, in the males, ten erect united filaments, five of them alternately shorter, and roundish versatile antheræ. PISTILLUM, a roundish trifurcated germen, three forked styles, and simple stigmas. PERICARPIUM, a roundish, trilocular, tricoecous capsule, and three roundish seeds.

There are several species, of which the following are those generally retained here in our hot-houses.

JATROPHA Manihot.

Manihot, or esculent Jatropha, commonly called Cassada, or Cassava.] Jatropha, with a thick fleshy root; an upright, thick, woody, pithy stalk, rising six or seven feet high; palmated leaves, of seven spear-shaped, smooth, entire lobes, five or six inches long, all uniting at their base, and spread out like an expanded hand; and male and female yellow flowers in umbels at the top of the stalk and branches, succeeded by three-furrowed capsules containing the seeds.

The root of this shrub, though of a poisonous quality, serves for bread to most of the inhabitants of the West-Indies, being first divested of its poisonous juice by expression; it is prepared by rubbing the root forcibly upon a strong copper grater, till reduced to a rough saw-dust-like powder, or meal, is then put into a press, to squeeze out the poisonous juice; and being sufficiently pressed and sifted, is made into bread, by spreading it two or three inches thick, upon an iron plate heated over a fire, and thus the parts join, incorporate, and become cake bread, which is accounted very nourishing; and if the meal is put into soup, it swells up considerably,

ably, which seems to prove its great abundance in substance.

Great quantities of this sort are cultivated in all the West-India islands for the above purposes.

¹*JATROPHA Urens.*

Stinging Jatropha] *Jatropha* with a thick fleshy root; an upright, ligneous, prickly, pithy stalk and branches, rising five or six feet high; palmated leaves, of five sinuated lobes, armed with stinging spines; and white flowers in umbels from the ends of branches.

²*JATROPHA Gossypifolia.*

Gossypium-leaved Jatropha] Hath a woody, branchy stalk, rising four or five feet high, set with clusters of bristly hairs; leaves divided into oval, entire lobes; and dark purple flowers growing in umbels at the ends of the branches.

JATROPHA Multifida.

Multifid Jatropha] Hath a thick, woody, pithy stalk, branching eight or ten feet high; large many-lobed leaves, having the lobes multifid or jagged into many points; and bright scarlet flowers, growing in umbels at the ends of the branches.

All these species of *Jatropha* are durable in root, stalk, and branches; the stalks are woody, generally very thick, somewhat succulent, and full of a white pith and milky juice; the leaves very large and elegant; and the flowers produced in large umbels, having male and female in the same umbel; the males are of one salver-shaped petal, and the females are of five petals, expanding in form of a single rose; they flower here annually in summer, and are frequently succeeded by ripe seeds, which are contained in roundish three-lobed capsules of three cells, having one seed in each cell.

As all the sorts are natives of the warmest parts of the world, they require a hot-house to preserve them in this country; so must be potted in pots of good light earth, and always continued in the stove, where they will exhibit a fine variety with their large elegant foliage, and umbellate flowers.

They should be always but moderately watered, especially in winter, for being mostly replete with a milky juice, much moisture might rot them.

Their propagation may be performed by seed, and cuttings.

By Seed.—The seed frequently ripens here, and is also imported annually from America,

which should be sowed in spring, in pots of rich light earth, and plunged in the bark-bed, where the plants will soon come up; and when a few inches high, prick them in separate small pots, give a little water, and plunge them also in the bark-bed.

By Cuttings.—In spring or summer, cuttings of the stalks and branches, six or eight inches long, planted in pots, and plunged in the bark-bed, will put out roots, and become proper plants. This is the common method of propagating the first sort in America for food.

IBERIS, Candy-tuft, or Sciatica Cress.

This genus comprehends hardy, herbaceous, low, flowery annuals for the borders, and under-shrubby perennials for the green-house; all of them of branchy bushy growth, from about six or eight inches to a foot and a half high; garnished with narrow entire leaves, and terminated by umbels of tetrapetalous flowers.

Class and order, *Tetradynamia Siliculosa.*

Characters.] *CALIX*, four small oval deciduous leaves. *COROLLA*, four oval, spreading, unequal petals, the two outer ones longest. *STAMINA*, four long and two short filaments, and roundish antheræ. *PISTILLUM*, a roundish compressed germen, short style, and obtuse stigma. *PERICARPIUM*, a roundish compressed bilocular capsule, and two oval seeds.

The species cultivated in our gardens are, two hardy herbaceous annuals, and two or three tender shrubby perennials.

Hardy Herbaceous Annual Kinds.

¹*IBERIS Umbellata.*

Umbellated Iberis, or Common Candy-Tuft.] *Iberis*, with herbaceous, short, round, very branchy stalks, of tufty growth, from about six to eight or ten inches high; small spear-shaped leaves, the lower ones serrated, the upper entire; and all the stalks and branches terminated by umbellate clusters of flowers of different colours in the varieties.

Varieties.] With white flowers—with red flowers—and with purple flowers.

All the varieties flower in June, and by different sowings may be made to flower to the end of summer; they were introduced to our gardens from Candia.

²*IBERIS amara.*

Bitter Candy Tuft.] Hath herbaceous, short, round, very branchy stalks, of bushy growth, from about eight to ten or

twelve inches high; small, spear-shaped, slightly-indented leaves; and all the branches terminated by racemose bunches of white flowers in June and July, &c.

Both these species and varieties are very hardy annual flowers, rise freely in the open ground, should generally be sowed in patches, and by different sowings from March till Midsummer, they will afford a succession of bloom from June till September, and produce great plenty of seeds.

Shrubby Perennial Kinds for the Green-house.

The two following low under-shrubby species being natives of Candia, and other warm parts, require shelter of a green-house here in winter.

³*IBERIS Sempervirens.*

Ever-green Shrubby Iberis, commonly called Tree Candy-Tuft.] Hath low under-shrubby stalks, very branchy and bushy, growing but ten or twelve inches high; very narrow acute entire leaves, remaining all the year; and white flowers in umbels at the ends of the branches, appearing great part of the summer.

⁴*IBERIS Semperflorens.*

Ever-flowering Shrubby Iberis.] Hath low under shrubby stalks, very branchy, spreading and bushy, growing a foot and a half high; wedge-shaped, obtuse, entire, ever-green leaves; and white flowers in umbels, at the ends of the branches, appearing at all times of the year.

Variety.] With white striped leaves.

The flowers of all these plants consist each of four small petals, are very numerous, terminating all the branches in umbellate clusters, so conspicuously, that the plants appear covered therewith; succeeded by abundance of seed in the annual sorts; but the shrubby kinds rarely produce any here.

The two annual species make a pretty appearance when disposed in patches in the flower-borders, sowed in spring where they are finally to remain; but as they continue only two or three weeks in beauty, it is proper to perform three or four different sowings from Feb. or March until June, to have a succession of bloom to the end of summer. Sow about half a thimbleful of seed in each patch of about five or six inches diameter, covering them with fine earth, near half an inch deep; and when the plants are an inch high, thin them to about six in each patch, that they

may have room to branch and spread, where by they will flower stronger, and continue longer in bloom, than if left thick.

The two shrubby perennial kinds, are naturally of low bushy growth, durable in root, stem, and branches, ever-green, and very floriferous, and merit admittance in every green-house collection, both as ever-greens, and for the beauty of their flowers almost throughout the year. They being impatient of frost, must be potted to move to shelter in winter; potting them in any good light earth, and place them in a green-house or garden-frame in winter. A few plants of each may also be planted in the full ground, in a dry sheltered sunny situation to take their chance, and will frequently stand tolerably well the year round, with only a light covering of long strawey litter in hard frosts.

The propagation of these two shrubby kinds and variety, is easily effected by slips and cuttings, from three to five or six inches long, planted any time from March till July, either in a hot bed or natural earth, affording them shade and water, and they will readily put out roots, and be fit for potting towards the end of summer.

ICE-HOUSE, a building sunk in the ground, serving as a repository to preserve Ice till summer, for various family-uses; the management of which generally belongs to the gardener.

This building is constructed like a well, mostly sunk in the ground as above observed, eight, ten, or twelve feet deep, walled with brick or stone, arched over at top, having a small door on the north-side, and over all a slated or thatched roof. The place for this building should be generally in some bye part of the garden, or some convenient place contiguous thereto: chusing a dry elevated situation, both that the Ice may not be liable to be melted by copious moisture, and that all moisture running from the Ice may readily drain off. It would be of much advantage if it could be contrived on or near the side of some hill, or sloping ground, where the base of the slope is lower than the bottom of the well of the building, for the more effectually draining off the moisture; let it, however, be contrived in as dry a place as possible, and so much elevated as the water may be easily carried off by drains to some lower ground; and should be in a part either within, or contiguous to the garden, where carts can readily bring in the Ice in winter.

The

I C E

The place being fixed on, a well must be digged, eight or ten feet diameter, and as much in depth, or more; observing, if the situation fixed on is somewhat elevated, and the ground of a dry gravelly, or sandy nature, not retentive of moisture, the pit or well may be wholly sunk below the general surface; but if rather low, or moist ground, it is advisable to have the well raised as much above the surface as the moisture may easily drain away. Having formed the cavity or pit of the well, then at bottom should be formed a hollow space for a drain, two feet deep, the sides walled with brick or stone, having at top a grate framed with strong wooden bars; from the bottom of this drain must be a small under-ground drain, to conduct the moisture quite away from the building. The sides of the main well must be walled round with brick or stone, two feet thick at least, and carried up to a proper height, leaving, near the top, on the north side, a space two feet and a half diameter, for the admission of the Ice, &c. and terminate the wall all round with a strong thick arch of the same materials carried over the top; and there should be another wall proceeding from within three feet below the top of the other, raising it also with an arch over the top of the first, leaving likewise a place for entrance; or, if this outer wall is not arched, raise upon it a wooden roof slated, tiled, or thickly thatched; observing if slated or tiled, a foot thickness of reeds or straw under it is proper, the better to exclude all air and heat of the sun; and from the door or mouth of the well, should be a porch continued a yard and a half outward, and one or two wide, walled on the sides, and arched at top, and a door at the outer end; and both the inner and outer doors made to shut perfectly close. The building thus far advanced, may then bank up earth around the out-side wall, the better to defend the Ice from all external causes, and finish with a coat of turf laid neatly all over the banking.

If the building is finished betimes in the summer, it will be dried enough for the reception of the Ice the following winter.

Therefore in winter take the opportunity of the first Ice, when about an inch or two thick; load it in carts, and bring it to the Ice house, shooting it down at the outer door; then, after having laid some clean straw, reeds or faggots of brush wood at the bottom of the well upon the wooden grate, cast in

I L E

the Ice, breaking it small, and ramming it close from time to time, that it may cement into one solid mass; observing, as you proceed, to lay some clean straw all round next the wall if possible, to preserve a vacancy to give passage to any moisture that may proceed from the top of the Ice.

As soon as the well is thus filled with Ice, shut the inner door, which should be thick, close, and made to fit exactly; then let all the vacant space between that and the outer door be closely filled with straw, and then shut the outer door as close as possible.

Thus the Ice will be preserved till summer; and if the house is perfectly air and moisture tight, will keep two or three years.

When the ice is to be taken out for use, be careful, in going in, always to shut the outer door before the inner one is opened; and as the ice will be all incorporated to a solid lump, you must have an iron instrument always in readiness to break it up, taking out no more at a time than is wanted.

I L E X, (formerly *Aquifolium*) the Holly-tree.

This genus furnishes hardy ever-green trees of great beauty and value, being proper both for useful and ornamental plantations; obtain twenty or thirty feet stature, adorned with long spinous, and serrated ever-green leaves, and short clusters of monopetalous four-parted flowers, succeeded by bunches of beautiful red berries in autumn and winter.

Class and order, *Tetrandia Tetragynia*.

Characters.] **CALIX**, is small, indented in four parts, and permanent. **COROLLA**, is monopetalous, and deeply divided into four roundish segments. **STAMINA**, four short filaments, and small antheræ. **PISTILLUM**, a roundish germen, no style, but four obtuse stigmas. **PERICARPIUM**, a roundish quadrilocular berry, and four oblong hard seeds.

There are but two species of *Ilex* common to the English gardens:—the common Holly—and Dahoon Holly; but of the former are many fine varieties.

The species are;

¹**I L E X** *Aquifolium*.

Aquifolium, or *Common Holly-tree*.] Hath an upright trunk, branching all around, twenty or thirty feet high, in a conic form; oval, waved, stiff, alternate leaves, having the edges and extremity terminated by sharp spines, pointing some upward, and some downward; and from the sides of the branches.

branches, small whitish flowers in short clusters, appearing in May; succeeded by bunches of roundish berries, ripening to a beautiful red colour in autumn and winter. Is a native of woods and forests in England.

Of this species are many curious varieties, both with entire green leaves, and with variegated, but the variegated kinds are the most extensive.

Green-leaved Varieties.] Common green-leaved, prickly Holly—smooth green Holly, the leaves being destitute of spines—narrow, serrated-leaved green Holly—green-leaved, yellow-berried Holly—box-leaved green Holly—hedge-hog green Holly, having the surface of the leaves closely set with small prickles, resembling those of a hedge-hog; hence it derived the name, (*Ilex Echinata*.)

Variegated sorts.] Common prickly Holly, with silver-striped leaves—with gold-striped leaves—with blotched leaves—smooth Holly with white-striped leaves—yellow-striped leaves—with blotched leaves—narrow striped-leaved Holly—blotched-leaved, yellow-berried Holly—cream-coloured Holly—copper-coloured Holly—white-leaved Holly—mottled Holly—hedge-hog silver-edged Holly—gold-edged hedge-hog Holly—white blotched hedge-hog Holly—yellow blotched hedge-hog Holly—painted lady variegated Holly.

There are many other varieties of the variegated Holly, differing a little in the size, form, and variegation of the leaves, and are retained in most of the nurseries, and named in their catalogues, often by that of the persons who raised them, or any name according to their fancy; but the sorts above mentioned being the principal varieties, most of the others belong to one or other of them.

All the varieties, both green and variegated kinds, are hardy ever-greens, of the tree and shrub kind, branching out every way from the bottom upward, and are finely adapted for all ornamental plantations; the common green sort also as a forest tree.

²*Ilex Cassine.*

Cassinoide Ilex, commonly called *Dahoon Holly*, supposed allied to the *Cassine*.] Hath an upright branching stem, rising fifteen or twenty feet high; oval lanceolate, serrated leaves, placed alternate; and small white flowers, in short thick clusters from the sides of the branches; succeeded by red berries, but rarely any in England. Is a native of Carolina.

Both these species of *Ilex*, together with all the varieties, are of the tree and shrub kind, and ever-green, being closely garnished with leaves all the year; and all the varieties of the *Ilex Aquifolium*, or common Holly, are extremely hardy, as well as very beautiful ever-greens, will prosper in any common soil and exposure; but the Dahoon Holly is rather tender, being subject to injury from severe frost, especially when young; after, however, having occasional shelter two or three years, of a frame, &c. in winter from hard frost, and being gradually hardened, it will bear our ordinary winter very well, in a dry soil and sheltered situation.

All the sorts are fine furniture for every ornamental plantation: nothing can make a finer appearance than a collection of the several varieties of the first species, suffered to take their own natural growth; they being beautiful all the year, but appear rather with greater elegance in winter than summer; and the variegated kinds being interspersed in the shrubbery, clumps, and other ornamental plantations, in assemblage with other hardy ever-greens, their beautiful variegations, with others of different hues, will greatly heighten the contrast; and their numerous clusters of red berries will add considerably to their lustre in the autumn and winter seasons. The Dahoon Holly is also a very fine plant, and worthy of admittance in every collection of ever-greens.

The first species was also in universal estimation for forming garden-hedges, both for ornament, and as fences, and makes the most beautiful hedge in the world. See HEDGES.

It was likewise greatly used to plant as detached or single objects to train into regular figures, as globes, hemispheres, pyramids, &c.

And is likewise considered as a forest-tree, as its trunk will acquire a considerable bulk, where the trees are suffered to grow up, as in the places of their natural growth, in many of our forests and woods. The wood of it being very white and hard, is valuable for many purposes in the turnery and cabinet work; for as it takes a fine polish, is very proper for several kinds of household furniture, inlayings, &c. hones for razors are made of this wood, and is fit for many other small hard uses.

Of the bark of this tree is made the composition called bird-lime. The bark being peeled

peeled about Midsummer, and put into a vessel of spring-water, and boiled about twelve hours, when the white bark will separate from the green; then lay the green bark on the floor of some cool cellar, covering it with any fresh rank weeds, and when lain a fortnight, pound it in a mortar till it becomes a tough paste; this done, wash it well in several waters till quite clean; put it then into an earthen vessel, to ferment and purge four or five days, scumming off all filth that arises; then change it into a fresh vessel for use; taking any quantity required, adding thereto a third part of well clarified goose or capon grease, mixing them well over a moderate fire, by constant stirring till cold, and the composition is prepared.

Propagation, &c.

The propagation of these trees is by seed, and by grafting and budding.

The common green Holly is raised plentifully from seed in the open ground; and all its varieties by grafting and budding upon stocks of that sort, raised as above from the berries: for sow the berries of any of the varieties, and they rarely produce any but plants of the common green kinds; so that there is no other certain method of continuing the variegated sorts, in particular, than grafting or inoculating shoots, or buds of them into common Holly stocks. The hedge-hog-Holly berries, however, very commonly produce plants of the same sort, with green leaves; but the variegated kinds thereof are continued by grafting or budding, &c. as observed for the other variegated kinds, &c.

By Seed.—The berries ripen in October and November, when a due quantity is to be gathered from any of the varieties; then observing, that as those seeds generally lie two years before they germinate, they may either be buried in a heap in a hole or pit for a year, to be preparing for vegetation, then taken up and sowed; or may be sowed at once as soon as gathered, as hereafter directed, and they will come up the spring-twelvemonth following. But as these seeds, like the haws of the hawthorn, &c. never grow till the second second spring, as just observed, it is common to bury them a year; that is, in some dry part of the garden, dig a hole or trench a spade deep, or a little more, and one or two wide, or in proportion to the quantity of berries; which directly put into the hole or

trench, and cover them over with some of the earth, five or six inches deep; or they may be buried in a large pot or tub, plunged over the top in the ground: in either method let them remain till next October; then having ground dug, and divided into four-foot-wide beds, with alleys between, trim with the rake or spade, an inch depth of earth evenly off the top of the bed; this done, take up the berries, and sow them evenly on the bed, beat them down gently with the back of the spade, and cover them with the earth an inch deep, and lightly smooth the surface: or the berries may be sowed in drills the above depth, making the drills six inches asunder: the berries thus sowed after being buried in the ground one year, will mostly come up the spring following.

I, however, have observed, that the berries sowed at once in the beds, as above, an inch deep, keeping the beds well weeded the following summer, that the berries all lying near the surface an equal depth, will all along enjoy an equal benefit of the air, sun, and showers, so as in the second spring they generally rise rather more regular and strong than those that were buried.

When the plants come up, keep them well hand-weeded, and if very dry weather, some water once a week will be of much service.

Two years let them remain in the seed-bed, then in spring plant them out in nursery-rows, two feet asunder, and a foot distance in each row, there to remain until they are of proper size to be finally transplanted; and the proper season for this is any time from the middle of September till that of March.

By Grafting and Budding.—All the varieties are, as above mentioned, continued by grafting or budding; and by either of which modes of propagation they may be multiplied at pleasure, upon stocks of the common Holly, raised from seed, as above directed, which after being planted out in nursery-rows, one or two years, they will be of proper size to graft or bud upon. The grafting is performed in March, by whip-grafting in the usual way; and the budding to be performed in July or August, according also to the usual method. See GRAFTING and INOCULATION.

The Dahoon Holly is also raised from seeds like the common kinds. The seeds are brought

brought annually from America, which, as soon as they arrive, should be either buried in the ground like the common Holly for a year, or may be sowed at once in pots of light sandy earth, and plunged to their rims in dry earth about a twelvemonth: then, in spring following, if plunged in a hot-bed will greatly facilitate their growth, being careful to inure the plants to the full air; afterwards plunge the pots in a shady border till October, then remove them under a hot-bed frame for the winter; in spring thin them out, and plant them in separate pots, to have occasional shelter of a frame for two or three winters, then transplanted in spring into the full ground.

IMPATIENS, Touch-me-not, and Balsamine, or Balsam.

This genus furnishes beautiful flowery annuals, of upright growth, branching a foot and a half, or two feet high; adorned with oval and spear-shaped leaves; and quinquepetalous irregular flowers.

Class and order, *Syngenesia Monogamia*.

Characters.] CALIX, is two-leaved, coloured, and placed on the side of the corolla. COROLLA, is ringent, of five roundish unequal petals, and a one-leaved, hood-shaped nectarium at bottom, terminating at the base in a spur or tail. STAMINA, five short incurved filaments, having the tops of the antheræ joined. PISTILLUM, an oval germen, no style, but a short simple stigma. PERICARPium, an unilocular capsule, opening with elasticity in five twisted, spiral valves, and roundish seeds, fixed to the columnar receptacle.

This genus derives the name *Impatiens* from the elastic property of its seed-vessel, which, when ripe, is so impatient of the touch, as to burst open with elasticity, and dart its seeds from their department with great velocity, especially the first species. There are only two species of this genera usually cultivated in the English gardens, both annuals; one is the *Noli me tangere*, or Touch-me-not, esteemed more for the singularity of its elastic capsules than beauty of its flowers: the other is that noted annual, Balsamine, or Balsam, comprehending, on several elegant varieties, producing numerous fine large flowers of singular beauty.

The species are;

¹IMPATIENS, *Noli me tangere*.

Noli me tangere, Touch-me-not, or Common Yellow Balsamine.] Hath fibrey roots; an up-

right, jointed, succulent stalk, a foot and a half high; oval alternate leaves; and from the axillas of the stalks, long, slender, branching foot-stalks, each sustaining many yellow flowers; succeeded by taper capsules, that burst open, and dart out their seeds with elastic force.

It grows wild in England, but is cultivated in many gardens for curiosity.

²IMPATIENS *Balsamina*.

Balsamina, or *Balsamine*, commonly called *Balsam*.] Hath a fibrey root; an upright, thick, succulent stalk, branching all around, a foot and a half or two feet high; long, spear-shaped sawed leaves, the upper ones alternate; and from the joints of the stalk and branches clusters of short foot-stalks, each sustaining one large irregular flower, of different colours in the varieties; flowering from June or July till September.

Varieties of this are.] Balsamine with single and double red flowers—single and double white flowers—single and double purple flowers—variegated single and double flowers—large, double, variegated, scarlet and white flowers—large, double, variegated, purple and white flowers, &c. all of which are most beautiful annuals, but being originally of Indian growth, are somewhat tender, requiring mostly to be raised and forwarded in hot-beds, &c.

Both the species and respective varieties are proper to be employed as plants of ornament to adorn the pleasure-garden; but the second sort, *Balsamina*, and varieties, are considerably the most beautiful, excelling also most others of the annual tribe. The flowers of both the species are moderately large, and consist each of five roundish unequal petals, and a monopetalous, hood-shaped nectarium, ending in a tail; the whole corolla is irregular, and somewhat resembling the ringent, or grinning flowers (see COROLLA *Ringens*); and are succeeded by plenty of seed in autumn, by which all the sorts are raised annually; the first sort in the common ground in autumn or spring; and the second chiefly in hot-beds in March and April. See their *Propagation*, &c.

The first species, *Impatiens noli me tangere*, being an indigenous plant of England, is very hardy; and is worth cultivation in gardens, both for the variety of its flowers, and the curiosity of its elastic seed-vessels, &c. will grow freely in the open borders, by seed in autumn or spring, sowed either where the plants are to remain, or for transplantation.

The

The *Impatiens Balsamina*, or Balsamine, is one of the finest annual flowers of our gardens; but being a native of India, is tender, not able to bear the open air here before May or June, and requires to be raised principally in a hot-bed in spring, under frames, &c. until June, as aforesaid; remarking, however, that the seeds will also grow in the natural ground in May, rarely before, and more freely then, if covered with a hand-glass, &c. but the plants so raised will not begin to flower so soon by five or six weeks, as those forwarded by artificial heat, under frames and glasses. All the varieties are of somewhat luxuriant growth, they frequently having stems thicker than good walking-canes, branching out into large heads, and every branch productive of abundance of flowers; and as the branches advance in length, furnish a succession of bloom for two or three months; observing that the variegated doubles have the greatest merit, which are sometimes as large as middling roses, and the petals multiplied in many series; and all the varieties produce seed plentifully in autumn.

The fine varieties of this elegant species, are commonly planted in pots to decorate fore-courts, and other conspicuous departments; and the more inferior varieties are generally disposed in the common borders, as all the varieties, after being raised as above hinted, until June, will grow freely in the open ground, the remainder of the summer.

Propagation and Culture, &c.

The propagation of both the species, and varieties in general, is by seed; remarking, that the plants being but of one summer's duration, the sowings must be performed annually.

The *Noli me tangere* may be sowed in autumn, i. e. September, October, or November, or early in spring, February or March, in any bed or border, either in patches where the plants are to remain, or for transplantation, half an inch deep; and when the plants are come up an inch or two high, thin them to three in each patch; observing the same if they are to be transplanted. From the scattered or self-sown seeds of this species in autumn, many young plants will rise naturally the following spring.

The *Balsamine* is always sowed in the spring, in March or April, and should be performed principally in a hot-bed, as before observed; and the plants continued therein till June,

and if under deep frames may be drawn up two or three feet high by the latter end of that month.

Particular attention is requisite to procure seeds of the fine variegated doubles, especially if intended to exhibit a grand shew of them in pots, or principal borders and flower-beds. Sow the seed either in pots of light rich earth, half an inch deep, plunging the pots in a hot-bed; or it may be sowed immediately in the earth of the bed in small drills the above depth: the plants will soon appear, which are to be managed as other annuals of similar temperature, with respect to giving air daily, and frequent moderate waterings. When they are two or three inches high, it is proper to prick them out, either in the same, or in a fresh hot-bed, under a proper frame; raising them up with the roots entire, and either plant some of the best in pots (thirty-twos), one plant in each, up to their seed leaves, and plunge the pots in the hot-bed, as observed for the seed, or plant them into the earth of the bed, four or five inches asunder: in either method give a moderate watering directly, and occasional shade from the mid-day sun till they are fresh rooted; repeating the watering frequently. After having grown here about a month, they will be so much advanced in growth as to interfere with each other, when those in pots may be turned out with the earth about their roots into larger pots (twenty-fours), to remain; which if plunged also in the hot-bed will greatly forward the plants. Those planted in the earth of the hot-bed, if any of them are designed for pots, should also be then taken up with balls and potted, and treated as above, giving water and occasional shade as before. As they all advance in growth, raise the frame, if necessary, that they may grow to their full height; for it is a principal property to have these plants of some considerable stature. See ANNUAL PLANTS.

They must remain constantly in the frame till June, then harden them gradually to the full air, so as they may be removed into it fully towards the middle or latter end of that month, according to their size, and temperature of the season; at which time also those designed for the borders should be transplanted therein with balls of earth about their roots, giving water at planting, repeating it daily, or as there shall seem occasion, till they have taken good root.

As soon as they are removed into the open air, both those in pots and in the full ground should have a tall stick placed to each for support, to which tie their stems neatly.

Let those in pots be often watered in dry weather; once or twice a day in very hot weather will be necessary.

All the varieties of Balsamine may be raised to a great perfection in a stove, with little trouble, at almost any time of the year; sowing the seeds in pots, and plunge them in the bark-bed, and when the plants are two inches high, plant them in separate pots, which plunge also into the bark-bed, to remain until the plants are grown up.

But in default of hot-beds, &c. these plants may also be raised in the common ground for an autumnal bloom: the seeds will not, however, succeed in the natural earth before May, and even then must be sowed in a warm dry border, or in pots placed in a warm situation, and if covered with hand glasses occasionally will be an advantage, though they will often come up without any shelter at all, and flower abundantly in August and September; sometimes too, seeds having scattered or sowed themselves the year before in the borders, will remain sound, and come up the following year in May or June without art, and flower all autumn, until killed by the cold.

I would, however, observe, that plants raised and forwarded in a hot-bed, arrive not only much sooner to perfection, so as to have the pleasure of their bloom six weeks sooner; but by being thus forwarded into bloom betimes in summer, they always produce the best seeds.

To save seeds of the fine variegated doubles, some pots of them should be placed when in full bloom, either in an airy glass-case, having the windows in front to open, or in some deep frame to be sheltered with the glasses occasionally from great autumnal rains, and cold nights; you will thereby have a much greater chance of having plenty of seed perfectly ripened.

INARCHING. See **GRAFTING**.

INFLORESCENTIA, *Inflorescence*, or manner of flowering of all kinds of plants.

The term *Inflorescence*, signifies the mode or manner in which flowers are produced upon the plants, which is various, though in all the known plants and trees in the world, there is but seven or eight different modes of flowering, which are expressed by the following terms.

Capitulum, Corymbus, Panicle, Racemus, Spica, Thyrsus, Verticillus, and Umbella; for an explanation of each of which, see each under its proper head.

INOCULATION, or budding, a method of propagation, practised occasionally for various trees, but more particularly the fruit-tree kind.

The work of Inoculation, or budding, is the inserting an eye or bud of one tree into the side of another, and the bud uniting therewith, shoots out into branches, becomes a tree, producing flowers and fruit the same in all respects as those of the tree from whence it was taken; thus any sort of tree may be multiplied at pleasure, since every bud will form a tree exactly of the same sort, though upon a different stock and root; as for example, insert buds of peach, nectarine, and apricot trees into plum-stocks, which being headed the spring after, the bud shoots and becomes the tree; which, though the root, and the bottom of the stem is a plum-tree, the upper branchy part being produced from the inserted bud, is a peach or nectarine, &c. and produces fruit exactly the same as that from which you took the buds. It is, therefore, as observed of grafting, &c. the only method by which we can with certainty continue and multiply the different approved varieties of many kinds of fruit and other trees; for although their seeds will readily grow and become trees, yet, as we formerly observed, sow the seed, or kernels of the finest varieties of fruit, not one tree out of a hundred, so raised, will produce any like the original, and but very few that are good, so variable are seedling fruit-trees, and many others; but the trees or stocks, so raised, being budded with the proper approved sorts, the buds produce invariably the same kind of tree, fruit, flowers, &c. continuing unalterably the same.

The work of budding is performed in summer, principally in July and August; by inserting buds into the sides of the stocks, leaving their heads entire, and the buds remaining dormant till next spring, when the stock being headed, they shoot forth with vigour.

This mode of propagation is particularly used for peaches, nectarines, and apricots, which succeed better by budding than grafting, and are usually worked upon plum-stocks raised from seed, and sometimes by suckers, layers, and cuttings, upon particular occasions,

sions, as noticed in their respective articles. Peach, nectarines, and apricots are also often budded upon their own stocks, i. e. stocks raised from the kernels of these kinds of fruit; they, however, are commonly more strong and durable upon plum stocks.

Plums and cherries are also very often propagated by Inoculation as well as by grafting; the cherry, however, is generally the most prosperous by the latter method, as being more apt to gum and go off by budding. Both these sorts being of the same genus, will grow upon stocks of each other, but much the best upon their own stocks, that is, plum upon plum, and cherry upon cherry stocks.

Apples and pears may likewise be propagated by Inoculation as well as by grafting, though as they grow freely by grafting, which being the most easy and expeditious, they are commonly propagated by that method.

In short most kinds of fruit-trees, and others that are propagated by grafting, will also succeed by Inoculation; grafting, however, is more particularly adopted for some sorts, and budding for others, as is always explained under their respective articles.

Many sorts of forest-trees, and flowering-trees, &c. both deciduous and ever-greens, may also be propagated by Inoculation, and is a certain method of propagation, to continue particular varieties, such as many of the variegated-leaved kinds, as the variegated hollies, &c. and many other sorts, which is always mentioned in their propagation and culture, under the proper genera.

The Inoculation for all sorts is commonly performed upon young trees, raised from seed, suckers, layers, &c. which, when raised purposely for budding and grafting upon, are called stocks, and which, when about half an inch thick in the bottom of the stem, or a little more or less, are of proper size for budding; though it may be performed upon stocks from the size of a goose-quill, to an inch or more big: remarking that all Inoculation must be performed principally upon stocks or trees of the same genus, for it is but few trees that will succeed upon stocks of a different genera. Peaches, however, and nectarines, being of the genus *Amygdalus*, grow freely upon the *prunus*, or plum-tree, as being very near related, and is the most common stock on which these sorts are usually budded. But in most other kinds of fruit-trees, and others, the stocks of the same genus or fraternity, must be strictly adhered to,

both for budding and grafting. See GENUS.

For instance, peaches, nectarines, and almonds, may be inoculated either upon their own, or plum-stocks, but principally upon the latter to have durable trees. Apricots being of the genus *Prunus*, must be budded chiefly on plum-stocks, or else upon their own. Cherries upon cherry-stocks; apples upon apples; pears upon pears, or upon quince-stocks, to have dwarfs. Observing also the same of all other kinds of trees and shrubs, that are propagated by Inoculating and grafting.

The stocks are very commonly raised from seed, i. e. the kernels or stones of the above sorts of fruit, &c. sowed in autumn or spring, in beds in the nursery, an inch or two deep; they will come up in April or May following, which when a year or two old, transplant them in nursery-rows, two feet asunder, and fifteen or eighteen inches distant in the rows; here to stand for budding, keeping them to one stem, and suffer their top to run up entire; and having two or three years growth, when about the size of your little finger at bottom, or a little more or less, they are of due size for budding; stocks are also often raised from suckers arising from the roots of the trees of the respective sorts; likewise by layers and cuttings. See STOCKS.

Note, Budding may also be performed occasionally upon trees that already bear fruit, when intended to change the sorts, or have different sorts on the same tree, or to renew any particular branches of a tree, performing the operation in the young shoots of the year, or of one or two years growth.

Of performing the Operation.

The Inoculation is always performed in summer, when the rind of the stock, and that of the cuttings for the buds, will readily separate from the wood; for the buds being cut off from the shoots an inch or more long, the woody part adhering thereto is stripped off, are then inserted into the side of the stock, between the rind and wood thereof, the head remaining entire at present; and is done by slitting the bark of the stock cross ways, and perpendicularly, as directed below; and the rind and wood being then divided, the bud is inserted between them; which remaining dormant till spring following, when the stocks are headed down to the place of insertion, the bud shoots forth, and forms the

new tree, which in some sorts will bear fruit in two or three years.

The proper season for performing the operation of budding is from about the middle of July until the middle or latter end of August: some however begin to bud in June, but the buds inserted so early, are apt many of them to shoot the same year, and the shoots not having time to harden, are very liable to be killed in winter; determine therefore upon the end of July, or first fortnight in August to perform the operation, and your buds will all remain dormant till spring when they will shoot with vigour.

The buds are to be taken only from the young shoots of the year, i. e. shoots of the same summer's growth, which must be cut from the trees of the sorts you intend to propagate. Chuse them from healthful thriving trees; and if fruit-trees, from such that bear the finest fruit of their respective kinds and varieties: from which cut a quantity of the best moderately strong young shoots, each day as they are wanted, and as they are gathered cut off all the leaves, not quite close, reserving about a quarter of an inch of their foot-stalks, trimming off also the soft unripened top-end of each cutting, then cover them from the sun and air, and take them out as you want them; observing as each cutting furnish many buds, they are to be cut off about an inch and a half long, one at a time, as they are inserted in the stock; remarking that those in the middle-part of the cutting are preferable to those towards each end, though in cases of scarcity of cuttings, every one of them may be used; one bud only is commonly inserted in each stock; some, however, place two, one on each side opposite.

The proper height to bud the stocks is various, and may be within from about three or four inches of the ground, to six feet or more; that is, to have dwarf-trees, they must be budded from within about three to six inches of the bottom, that they may first furnish branches near the ground. If for half-standards, bud at the height of three or four feet; and if for full standards, at from about five to six or seven feet height; so that you must train your stocks accordingly, some for dwarfs, some for half standards, and others for full standards, as is more fully particularized under the several articles. I would remark, however, that for half and full standards, the budding may, if you please, be performed as low in the stock as for dwarfs,

and the first shoot from the bud trained up to a proper height for a stem.

The proper implements and materials for budding, is a small budding-knife, having a flat thin haft, to open the bark of the stock, to admit the buds, and a quantity of new bass strings to tie them.

To proceed to the operation.—Observe in the operation of budding, the head of the stock is not to be cut off, as in grafting, but the bud is inserted into the side, and the head to remain entire till spring after, and then cut down; therefore fix on a smooth part on the side of the stock, at the proper height, rather on the northward side, away from the sun, and with your budding-knife make a horizontal cut across the rind of the stock, quite through to the firm wood, then, from the middle of this transverse cut, make a slit downward perpendicularly an inch or more long, going also quite through to the wood. This done, proceed with all expedition to take off the bud, holding the cutting in one hand with the thickest end outward, and with the knife in the other hand, enter it about half an inch, or more, below a bud, cutting near half way into the wood of the shoot, continuing it with one clean slanting cut, about half an inch or more above the bud, so deep as to take off part of the wood along with it, the whole about an inch and a half long; then directly with the thumb and finger, or point of the knife, slip off the woody part remaining to the bud; which done, observe whether the eye or gem of the bud remains perfect; if not, and a little hole appears in that part, it is improper, and another must be prepared; this done, placing the back part of the bud between your lips, expeditiously with the back of the knife, or rather the flat haft thereof, separate the bark of the stock on each side of the perpendicular cut, clear to the wood for the admission of the bud, which directly slip down close between the wood and bark to the bottom of the slit, and then cutting off, if necessary, the top-part of the bud even with the horizontal cut, to let it completely into its proper socket; let the parts then be immediately bound round with a ligature of fresh bass, previously soaked in water to render it pliable and tough, beginning a little below the bottom of the perpendicular slit, proceeding upward closely round every part, except just over the eye of the bud, and continue it a little above the horizontal cut, not too strait, but just sufficient

cient to keep the whole close, exclude the air, sun, and wet, and promote the junction of the stock and bud. In this manner proceed with the Inoculation of every stock till the whole is finished. The junction of the stocks and buds will be effected in three weeks; and next spring, the head of the stock being cut off, the buds will push out, each producing one shoot, sometimes a yard or more long by the end of summer.

This operation of budding may to those unacquainted, appear a tedious work; but an expert hand will bud several hundred in a day.

In a fortnight at farthest after budding, you will be able to judge which buds have taken, by their fresh appearance.

Three weeks, or thereabouts, after the operation, all those buds that have succeeded, will be firmly united with the stock, and the parts be swelled, and require the bandage to be loosened: let, therefore, the tyings be then taken wholly away, that the buds may have full liberty of growth, in common with the other parts of the stock; which is all that is necessary to be further done until spring, when the stocks must be headed down to the bud.

In spring, about February or March, just before the trees begin to shoot, cut off the head of the stock sloping, exactly above the bud, not three or four inches higher as is commonly done; after this, the whole effort of the stocks being directed to the buds, they will soon push forth strong, one shoot from each bud; many shoots will also arise from the stock, but these must be constantly rubbed off as often as they appear, that all the powers of the stock be collected for the vigour of the bud-shoot, which now commences the tree, and by the end of summer will, in some sorts, be advanced three or four feet high; and in the autumn or spring following, the young trees may be transplanted into the places where they are to remain, or may remain longer in the nursery as shall be convenient, according to the purposes for which they are designed.

Observe, however, that wheresoever the trees are, if designed to be dwarfs, the first shoot from the bud, should in the spring after it is produced, be shortened or headed down to four or five eyes, to force out first some lower shoots near the bottom, as directed for dwarf-trees, espaliers, &c. but if designed for half or full standards, and if they were budded

at proper height at first in tall stocks, and designed for detached standards in the open ground, the first shoot of the bud may either be shortened as above, to four or five eyes, to provide lateral branches near the top of the stem, to form a spreading head; or may be suffered to grow up in height, and branch out in its natural way, whereby it will form a more erect head of loftier growth; remarking, however, that such full or half standards as are designed for walls, and were budded high on the stocks, must necessarily have the first shoots headed down in the spring following, to force out lateral shoots to furnish the allotted space of walling; observing again on the other hand, that trees designed for any sort of standards, and are budded low in the stock, the first shoot of the bud must be trained up for a stem to a proper height before it is stopped; and when arrived to its proper stature, should be topped to throw out shoots to form a head at the desired height, either for walls or open-ground standards. See DWARF-TREES, ESPALIERS, WALL-TREES, and STANDARD-TREES, &c.

For the further management of budded trees, see the different articles under their proper genera, where the general culture of each sort, both dwarfs and standards, is fully exhibited.

IPOMOEA, *Quamoclit*, or *Scarlet Convolvulus*.

The plants are herbaceous, twining climbers, natives of the Indies, consisting of tender annuals and perennials of the flowery kind, rising with twining stalks upon support six or eight feet high, adorned with simple, cordated leaves, and monopetalous flowers.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, is small, five-parted, and permanent. COROLLA, is monopetalous and funnel-shaped, the tube very long and nearly cylindric, and the limb five-parted and spreading at top. STAMINA, five long filaments, and roundish antheræ. PISTILLUM, a roundish long style, and headed stigma. PERICARPIUM, a roundish trilocular capsule and three seeds.

There are several species, but not more than one common to the English gardens, which is a climbing flowery annual, very nearly allied to the *Convolvulus*.

IPOMOEA *Coccinea*.

Scarlet Ipomoea, commonly called *Scarlet Convolvulus*.] Ipomoea, with long, slender, twining stalks, rising upon support six or seven

ven feet high; heart-formed, pointed leaves, angulated at the base; and from the sides of the stalks and branches, many slender foot-stalks, each supporting several large funnel-shaped, beautiful scarlet flowers.

Variety] With orange-coloured flowers.

Both the varieties are annual, rise from seed in spring, flower in July and August, &c. ripen seeds in September and October, and wholly perish soon after.

They are tender, require to be raised and forwarded in a hot-bed until the middle or latter end of May, or beginning of June, according to the temperature of the season; and then may be planted out to adorn the borders, and some may be planted in pots to move occasionally to ornament any particular place; in either method, you must have sticks placed for them to twine upon.

The propagation is by seed annually, in March or April, in a hot-bed, along with other annuals of similar quality; may be sowed in small drills, half an inch deep; and in May or June, as aforesaid, plant them out into the open ground; or, if when the plants are come up an inch or two high, they are taken up and pricked down upon the same, or rather in a new hot-bed, it will forward and prepare them better for final transplantation: or the seed may be sowed in small pots, three or four seeds in each, and the plants may be turned out with the earth about their roots, where they are designed to flower: observing during their residence in the hot-bed, to admit air, and give refreshment of water, as directed for annuals of the same temperature. See ANNUAL PLANTS.

IRIS, *Flower-de-luce*, or Flag-flower, &c.

This genus is very comprehensive in a numerous family of herbaceous, flowering perennials, both of the fibrous, tuberous, and bulbous-rooted kind, producing thick annual stalks, from three or four inches to a yard high, terminated by large hexapetalous flowers, having three of the petals reflexed quite back, and three erect, most of which are very ornamental garden flowers.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, a permanent spatha. COROLLA, six oblong obtuse petals, the three outer are reflexed back, the interior ones erect, and all of them united at the base. STAMINA, three subulate filaments lying on the reflexed petals, and oblong depressed antheræ. PISTILLUM, an oblong germen under the corolla, short style, and large stigma divided into three broad segments. PERICARPIUM,

an oblong, angular, trilocular capsule, and many large seeds.

To this genus is now added, the *Hermodystylus*, or Snake's head Iris—*Xiphium*, or Bulbous Iris—and a species of *Sisyrinchium*; their generic characters determining them to be all species of this genus. Each of these, however, is exhibited under a separate head.

The flowers of all the species of this genus have great singularity in their structure; they are large, consisting each of six petals, the three interior ones standing erect, called standards, and the outer ones reflexed backward, called sails, which in some species are bearded, having a downy matter running along the middle; other species are unbearded, having the bent petals smooth, and in the centre a sort of three-lobed nectarium, like three smaller petals, one generally inclining towards each fall.

So that they may be divided into two classes, the bearded, and unbearded kinds.

Bearded Kinds.

These are mostly of the sword leaved kind; have thick, knotty, fleshy, perennial roots; sending up annually clusters of long, flat, ensiforme, erect leaves, from three inches to two feet in length; and amidst them upright thick flower-stalks, of various statures in different sorts; ornamented in most species with leaves the same as the radical ones; and terminated by the flowers, in some but one, others two, three, or more, one above another, appearing mostly in May, June, and July; succeeded in several of them by plenty of seed.

¹IRIS *Pumila*.

Dwarf Austrian Iris.] Hath a large, fleshy, knotty root, rising above-ground; crowned with many broadish erect leaves, three or four inches long; and short erect flower-stalks, three inches high; each terminated by one large bearded flower, of different colours in the varieties; flowering in May.

Varieties are.] Dwarf Iris, with pale-purple flowers—deep-purple flowers—blueish flowers—with red flowers—blush-coloured sweet-scented flowers—white flowers—and with variegated flowers.

All these varieties are very pretty garden flowers, for the fronts of borders, &c.

²IRIS *Susana*.

Chalcedonian Black and White Iris.] Hath a thick, fleshy, spreading root; crowned by several long, narrow, sharp edged, erect leaves,

leaves, embracing one another at the base; and upright, jointed, firm stalks, two feet high; each terminated by one very large bearded flower, having the three up-right petals, or standards, very broad, and variegated with black and white stripes and dusky spots, and the three falls or bending petals almost black, and constructed like an open mouth, the stamina representing the tongues; so that the whole flower exhibits a strange and formidable appearance.

²*IRIS Germanica.*

German Violet-coloured Iris.] Hath a thick, jointed, fleshy, spreading root; clusters of sharp-edged, pointed leaves, a foot and a half long, embracing each other below, but spread out fan-fashion above; and upright, branchy flower-stalks, two feet high; sustaining many bearded violet-coloured flowers, one above another, the lower ones having foot-stalks; flowering in the end of June and July, succeeded by plenty of seeds.

⁴*IRIS Florentina.*

Florentine White Iris.] Hath a thick, fleshy, spreading root; cluster of broadish sharp-edged leaves, a foot and a half long; and upright flower-stalks, taller than the leaves; terminated by two or three close-fitting white flowers; appearing in June and July.

⁵*IRIS Squalens.*

Squalid Purple and Yellow Iris.] Hath thick fleshy roots; broad, rough, sharp-edged leaves, a foot and a half long; and upright flower-stalks, near two feet high; sustaining several bearded, ill-coloured, purple and yellow flowers; appearing in June and July.

⁶*IRIS Sambucina.*

Sambuca-scented Violet and Blue Iris.] Hath thick roots; broad, sharp-edged, pointed leaves, a foot and a half long; and upright flower-stalks, about two feet high; terminated by several bearded, violet and blue flowers, having the falling petals plane, and the erect ones emarginated; and smell strongly like elder; appearing in June or July.

⁷*IRIS Variegata.*

Variegated Hungarian Iris.] Hath thick knotty roots; crowned by many broad, sharp-edged, pointed leaves, near two feet long; and upright stalks, two feet high, branching near the top; each division supporting two or three large bearded flowers, having the erect petals yellow, the falls white, striped with purple, and variegated stigmas; flowering in June.

⁸*IRIS Aphyllis.*

Leafless, or Naked-stalked, purple and White Iris.] Hath thick roots; very broad leaves, a foot or two long; and upright leafless stalks, the length of the leaves; terminated by three or four large, bearded, bright purple flowers, having the falls striped with white; appearing in May.

⁹*IRIS Biflora.*

Twice-flowering Portugal purple Iris.] Hath a thick, knotty root; broad short leaves, eight or ten inches long; and upright stalks, six or eight inches high, branching at top into foot-stalks; each supporting two or three bearded, deep-purple flowers; appearing in May, and sometimes again in autumn.

With Unbearded Flowers.

Most of these are also of the sword-leaved kind, and mostly with thick fleshy roots, all perennial, with the leaves rising in clusters from the root annually, and amidst them the flower-stalks, supporting the flower at top.

¹⁰*IRIS Verna.*

Spring flowering Dwarf Virginia Iris.] Hath a fibrous root; crowned by a cluster of very narrow grass-like leaves, eight or nine inches long; and upright flower-stalks, shorter than the leaves; terminated by one unbearded, sweet-scented flower, having blue standards, and purple falls; flowering early in May.

¹¹*IRIS Versicolor.*

Variable-coloured American Iris.] Hath a thick fibry root; sword-shaped leaves, a foot long; upright taper stalks, a little taller than the leaves; terminated by two or three unbearded flowers above one another, having light-blue standards, and deep purple falls, variegated with a broad white line through the middle; flowering in June.

¹²*IRIS Graminea.*

Grass-leaved Austrian Iris.] Hath fibrey roots, narrow, flat, grassy leaves, about a foot long; upright, two-edged stalks, shorter than the leaves; terminated by two or three smallish unbearded flowers above each other, having reddish purple standards variegated with violet, and light purple falls, with a broad yellow stripe along the middle, adorned with purplish streaks; and a sexangular germen; in July.

¹³*IRIS Spuria.*

Stinking narrow-leaved Meadow Iris.] Hath a thick fibrey root; crowned with many very narrow leaves, near a foot long; and upright taper

taper stalks, a little taller than the leaves; adorned with three or four unbearded flowers, having pale blue standards, and purple variegated falls, with a white line down the middle; and a sexangular germen; flowering in July. Is a native of Germany.

¹⁴IRIS *Martinicensis*.

Martinican Blackish yellow Iris.] Hath long narrow leaves, upright stalks, supporting two or three unbearded blackish-yellow flowers, glandulous near the base, and a trigonous germen; flowering in June or July.

¹⁵IRIS *Sibirica*.

Siberian Narrow-leaved blue Iris.] Hath thick fibrey roots; crowned with narrow sword-shaped leaves, a foot and a half long; upright foot-stalks taller than the leaves; terminated by two or three unbearded flowers above each other, having light blue standards, and deep blue falls striped with white; flowering in July, and ripen plenty of seeds.

¹⁶IRIS *Fætidissima*.

Most Stinking Iris, commonly called Stinking Gladwin.] Hath thick fibrous roots; sword-shaped grass-green leaves, fifteen or eighteen inches high; and upright one-angled flower-stalks, about the height of the leaves; sustaining two smallish unbearded purple flowers, having the interior petals spreading; flowering in July.

Variety.] With striped leaves.

Both the varieties retain their leaves all the year, and the striped-leaved sort forms a pretty variety at all seasons; they grow wild in marshy places in England, but are admitted into gardens for variety.

¹⁷IRIS *Pseudacorus*.

Bastard-acorus, or common yellow Flag-flower of our marshes.] Hath a thick, fleshy, spreading root; crowned with many long, sword-shaped, erect leaves, two or three feet in length; and upright firm flower-stalks, a yard high, terminated by a few yellow flowers, having the interior petals less than the stigma; flowers in June. It grows wild in marshy places, and standing waters all over the kingdom, and is only cultivated sometimes for variety.

All the above seventeen species are very hardy perennials, of great duration in root, but in most are annual in leaf, and all of them renew their flower-stalks annually in spring, and decays in autumn soon after they have flowered and produced seeds. They are all proper ornamental furniture for the compartments of the pleasure-gardens, either in bor-

ders or to intermix in the shrubbery-clumps, between the shrubs and trees, for they will prosper in any common soil and situation, and effect a very agreeable variety during their bloom; which in the different sorts is continued two or three months, i. e. May, June, and July.

They may be planted at almost any time from September till March, though September, October, and November is the most eligible season, as they will be more firmly rooted, so as to flower strong the following summer; observing, that as most of the sorts are apt to spread greatly at root, they should be reduced occasionally, either by slipping them, or transplanting every two or three years, or as you shall see necessary to preserve them within due compass.

The propagation of all the sorts is effected abundantly by dividing their roots, as they multiply exceedingly by off-sets, which may be parted any time from September until March. I would, however, advise it to be done principally in autumn, in September, October, or November, whereby they will be more firmly rooted, and flower in good perfection the following summer.

They are also easily raised from seed, which is the method to obtain new varieties: sow the seed in autumn, soon after it is ripe, any time in September, in a bed or border of common earth, and rake it in, and the plants will rise in spring following: which in autumn should be transplanted, and they will flower a year or two after.

Hermodactyle Iris.

This was formerly a distinct genus, but its generic *Characters* prove it only a species of *Iris*.

¹⁸IRIS *Tuberosa* (*Hermodactylus*).

Tuberous-rooted Iris, or the Hermodactyle, or Snake's-head Iris.] Hath a large tuberous root, consisting of large tubers; sending up several long tetragonous, or four-cornered leaves; and amidst them an upright stalk, a foot or more high, terminated by one large purple unbearded flower, in April or May; but rarely produce seed in England.

It is a native of Arabia, but is very hardy, and long an inhabitant of our gardens; is easily propagated by its tubers, which the main roots furnish by off-sets annually, and should be taken off at the decay of the leaves in summer.

This

This species is remarkable for striking its roots deep into the ground, often so low as to lose themselves, especially in very light soils, in which case they should be annually transplanted, when their leaves decay.

Xiphium, or Bulbous Iris.

The *Xiphium*, including the bulbous and Persian Irises, was formerly considered as a distinct genera; but, according to the Linnæan system, all the sorts are now retained as species and varieties of this genus, their characters agreeing exactly with the common *Iris*; the flowers consisting of six petals, three of them standing erect, and three reflexed backward, &c.

There are but two species, the common Bulbous Iris, and Persian Bulbous Iris; both very hardy, and the former of which is prolific in many fine varieties; the latter is also a beautiful spring flower.

¹*IRIS Xiphium.*

Xiphium, or Bulbous Iris.] Hath a large roundish, fleshy, bulbous root; sending up several awl-shaped, channelled, sharp-pointed leaves; amid them an upright shorter flower-stalk, from half a foot to a foot or more high; terminated by two or three large beautiful flowers of different colours in the varieties.

Varieties of this are.] Common blue flowered bulbous Iris—with violet-coloured flowers—white flowers—purple-flowered—yellow flowering—with blue standard petals and white falls—with blue standards and yellow falls—with striped flowers—broad-leaved with blue flowers—broad-leaved purple-flowered—sweet-scented blue-flowered—sweet-scented purple flowers—and with variegated sweet-scented flowers: with many other intermediate varieties.

All these sorts flower beautifully in May and June, in the open borders, &c. though some a month or six weeks earlier than others, and are succeeded by plenty of seeds in autumn; and may be propagated plentifully by off-sets of the root, like other bulbs.

²*IRIS Persica.*

Persian Bulbous Iris.] Hath a large oval bulbous root; sending up several awl-shaped channelled leaves, six inches long; and amid them an upright short stalk, three inches high, crowned by one or two large elegant flowers, with the interior petals spreading and serrated, having whitish-blue standards, and pearly white falls, variegated with yellow and purple, and of a fragrant scent; appearing in

February and March. It is valuable both for its early bloom and the great beauty of its flowers.

Both the above species and respective varieties of bulbous Iris, have great merit as flowery plants; will grow freely in any of the common borders, and are pretty ornaments for the pleasure-garden; planting them in autumn, to adorn the principal borders, in small patches towards the front, setting them about three inches deep; they will all flower the following year at their proper season; and the bulbs will abide for years, and flower annually; it is, however, proper to take them up every second or third year at least, at the decay of the leaves, to separate the off-sets, &c.

The propagation of both these species of bulbous Iris, and varieties, is principally by the off-sets of the roots, like other bulbs, which they afford in tolerable plenty, especially if suffered to remain undisturbed two or three years, when they will be greatly increased; the proper time for lifting the roots and separating the off-sets, is in summer, when the leaves decay, managing them as other bulbs. See *BULBUS*.

They are also propagated by seed to gain new varieties. Sow it in September, in a bed of light sandy earth, that has only the morning sun, covering it with fine earth half an inch deep; or it may be sowed in pots, boxes, or tubs of the like light soil, which may be moved at pleasure to a warm, or shady situation at different seasons: the plants will rise in spring following, which in the summer twelvemonth after, at the decay of the leaves, remove from the seed-bed, and plant them into another, three inches apart, and two deep, to remain two or three years, when they will flower sufficiently strong to discover their properties; then are to be managed as the other large bulbs.

Sisyrinchium Iris.

²¹*IRIS Sisyrinchium (Bulbosa).*

Bulbous Sisyrinchium.] Hath a double bulbous root, growing one upon another; crowned with long, narrow, channelled, sharp-pointed leaves; and an upright firm flower-stalk, half a foot high, terminated by two or three smallish blue flowers; appearing in summer.

Variety] With yellow spotted flowers.

This species is also proper furniture to increase the variety of bulbous-rooted flowers; and

I T E

and its culture and propagation is the same as the two former species of bulbous Iris.

ITEA, Itea.

One species only, a hardy deciduous flowering shrub, constitutes this genus, and is proper for the shrubbery.

Class and order, *Pentandria Monogynia.*

Characters.] *CALIX*, is monophyllous, acutely five-parted at top, and permanent. *COROLLA*, five long spear-shaped petals. *STAMINA*, five awl-shaped filaments, and roundish antheræ. *PISTILLUM*, an oval germen, cylindric permanent style, and obtuse stigma. *PERICARPIUM*, an oval, long, unilocular capsule, terminated by the style, and contains many small seeds.

The species is;

ITEA Virginica.

Virginian Itea.] Hath a shrubby stem, branching out irregularly all around from the bottom upward, six or seven feet high; spear-shaped, slightly-sawed, alternate leaves; and all the branches and shoots terminated by long erect spikes of white flowers, making a fine appearance in July.

This beautiful shrub should have a place in the most conspicuous shrubbery compartments, for being so very floriferous as to appear covered with its bloom, continuing in great beauty a fortnight or three weeks.

It is propagated by seed and by layers.

The seeds arrive from America in spring, when they should be sowed in pots or boxes of light sandy earth, and plunge them in the ground till next year in March; then, if the plants are not come up, plunge them in a hot-bed, which will greatly promote their growth, giving frequent waterings all the summer, and allow them the shelter of a frame or green-house the two first winters; then in spring after plant them out in nursery rows a foot asunder, and in two or three years, they will be ready for the shrubbery.

Layers of the young shoots made in autumn or spring, making a slit in the part to be layed, will be rooted by autumn following.

IVA, Jesuit's-Bark Tree.

There are two species, one a hardy deciduous shrub for the shrubbery, and the other an herbaceous annual, but the former is the sort principally cultivated.

Class and order, *Monoecia Pentandria.*

Characters.] *CALIX*, male and female flowers apart on the same plant, having a roundish permanent cup, containing many

J U G

florets. *COROLLA*, a compound convex flower, having many funnel-shaped male florets in the disc, and the females are apetalous. *STAMINA*, five bristly filaments, and erect antheræ. *PISTILLUM*, an oblong germen, two hair-like styles, and acute stigmas. *PERICARPIUM*, none, solitary seeds lodged naked on the proper receptacle.

The species is;

IVA Frutescens.

Shrubby Iva, commonly called Jesuit's-Bark Tree.] Hath a shrubby stalk and branches of slender growth, rising eight or ten feet high; spear-shaped sawed leaves; and monoecious pale purple flowers, in clusters from the ends of the branches, in August or September, but no seeds in England.

It is an American shrub, but hardy enough to grow here in the open ground, and is proper for the shrubbery plantations, allowing it a dry soil, and sheltered situation.

Its propagation is by layers and cuttings; lay the young branches in spring, and they will be rooted and fit to transplant in autumn; and plant cuttings of the young shoots in April or May, in a shady border, they will readily emit roots.

JUGLANS, Walnut-Tree.

This genus consists of large, hardy, deciduous trees, eminent as fruit-trees, forest-trees, and for ornament, attaining from thirty to forty or fifty feet stature, branching into large very spreading heads, adorned with elegant pinnated leaves, and monoecious flowers in amentums and clusters.

Class and order, *Monoecia Polyandria.*

Characters.] *CALIX*, male and female flowers apart on the same tree; the males in oblong, cylindric, scaly amentums, each floret having a scale for its cup; and female flowers in close-fitting clusters, with a four-pointed cup to each floret. *COROLLA*, in the males, is a six-parted plane floret, and in the females, is acute, four-parted, and erect. *STAMINA*, in the males many short filaments, and acute erect antheræ. *PISTILLUM*, in the females, a large oval germen under the calix, two short styles, and large reflexed stigmas. *PERICARPIUM*, a large, oval, drupaceous, unilocular fruit, inclosing a large oval or roundish knotted, furrowed nut, nearly quadrilocular, having a four-lobed, furrowed kernel.

There are three species common to our English plantations, each comprehending some varieties, though the common walnut

is

is that which is most generally cultivated, both as a fruit and timber-tree; all the others, however, are equally hardy, produce eatable fruit, though with much smaller kernels than the common sort; therefore the common walnut is the most eligible for general culture for the fruit; but considered as ornamental and forest trees, all the sorts are proper.

The species are;

¹*JUGLANS Regia.*

Common Walnut-tree.] Grows fifty feet high, or more, with a large upright trunk, branching into a very large spreading head; large pinnated leaves, of two or three pair of oval, smooth, somewhat serrated lobes, terminated by an odd one; and monoecious flowers; succeeded by clusters of large green fruit, enclosing furrowed nuts of different shapes and sizes in the varieties; ripen in September and October.

Varieties are.] Common oval Walnut—round Walnut—large Walnut—small-fruited Walnut—double Walnut—early Walnut—late Walnut—tender thin-shelled Walnut—hard thick-shelled Walnut.

There are some other seminal variations, for plants raised from the nuts of the same tree, will often produce different varieties of fruit, as is common with most other fruit-trees. The wood, leaves, and outer covers of the fruit of all the varieties of this species is extraordinary bitter, and the skin of the kernel is a strong bitter astringent, which should be peeled off, the kernel then eats very palatable with an agreeable flavour.

²*JUGLANS Nigra.*

Black Virginian Walnut.] Grows forty or fifty feet high, with a large trunk, and very branchy spreading head; large pinnated leaves, consisting in different varieties, of from five or six to ten or twelve spear-shaped, sawed lobes, terminated by an odd one, the lower lobes the least; and monoecious flowers, succeeded by rough hard-shelled nuts, differing in shapes and size in the varieties.

Varieties are.] With round fruit—with oblong deeply-furrowed fruit—with aromatic-scented leaves.

³*JUGLANS Alba.*

White Virginia Walnut, commonly called Hickory Nut.] Grows thirty feet high, having pinnated leaves, which, in different varieties, consist of from two or three to six or seven pair of spear-shaped sawed lobes, terminated by an odd one; and monoecious flowers;

succeeded by oval smooth nuts, having a whitish shell.

Varieties of this are.] Smooth-barked white Virginia Walnut—shag-bark white Virginia Walnut, having the stem and older branches covered with a rough scaly bark—with large fruit—with small fruit.

The flowers of all these trees are male and female apart on the same plant; the males commonly in oblong cylindric catkins, and the females in close clusters, appearing generally in April and May; succeeded in the females, by large roundish green fruit, each including one nut, having a hard shell filled with an eatable kernel; but those of the common Walnut are the largest and finest flavoured; all of them ripening in September and October.

All the three species and respective varieties are very hardy, and prosper in any common soil; they are all deciduous; their leaves come out in May, and fall off in October and November.

They are all employed occasionally in plantations, both as forest-trees for timber, and to intermix in plantations for ornament, and the *Juglans Regia* also as a fruit-tree; all the sorts are also peculiarly adapted to plant as detached single objects in parks and paddocks, as having very large, regular spreading heads; they have likewise a fine effect disposed in groups of three or more trees together at sufficient distances from one another for their heads to spread; and are also proper to use in assemblage to form avenues, and to plant in hedge rows, in the boundaries of fields and other open places, for they will thrive either on plains, the sides of hills, or in vales, in almost any ground, but delight most in a loamy soil.

They are all of large spreading growth; but the first and second species are the largest growers; their trunks acquire a considerable stature and substance, and divide into very large arms, forming monstrous spreading heads, particularly the common Walnut; the black Virginia Walnut, however, grows rather the most upright.

Considered as forest or timber-trees, they are also all very proper to be admitted of that tribe, and placed among the hardy deciduous kinds, for their timber is valuable for many purposes; not, however, where strength is necessary, it being of a very brittle nature, but the cabinet-makers and joiners esteem it

greatly for several sorts of household furniture, and other light works, for the wood being beautifully veined, takes a fine polish, and the more knotty it is, the more it is valued for particular purposes.

With respect to their merit as fruit-trees, all the sorts produce fruit here, but the common Walnut the largest, most plentiful, and finest eating; the others having very small kernels. The common Walnut-tree, therefore, is the only proper species of *Juglans* to cultivate as a fruit-tree for the sake of the Walnuts; and it may be planted as standards in orchards, like other fruit-trees, but at a greater distance, as having large spreading heads; or, are well adapted for planting round the boundaries of orchards, where they will also guard the other lesser fruit-trees from boisterous winds; and may be planted as fruit-trees in parks or paddocks, and in rows round fields, or in any open place where thought convenient; they are raised plentifully from the nuts, and planted out in nursery rows, as directed below; and in five or six years the plants will be six or eight feet high, with firm stems and handsome heads, when they may be planted out where they are to remain; though the younger these trees are planted out, the better they will succeed; or if the nuts were planted at once where the plants are always to stand, the trees would still be of more quick and larger growth; observing in either mode of planting, that as the trees branch out into very spreading heads, they should stand thirty or forty feet each way asunder; planting them with their heads entire, and suffer their branches and shoots always to advance according to their own natural growth, without shortening; for the trees produce their fruit on the young shoots arising towards the extremity of the branches, so should never be shortened except in cases of very irregular growth, or great ramblers. See STANDARD FRUIT-TREES.

It is, however, a common opinion, that beating these trees with large poles to get down the fruit, (which consequently breaks many of the shoots) promotes their bearing; the only reason that can be assigned for this opinion is, that the trees producing their fruit upon the young shoots of the last and same year, as aforesaid; and that by beating the branches with long poles, as the most expeditious way of gathering the fruit from large trees, it breaks off many older shoots, also the ends of many of the young ones, which

probably, like shortening with a knife, forces out a greater supply of young shoots the following year for bearing. I should, however, in the operation of beating down the fruit, be for saving the branches as much as possible.

These trees seldom begin to bear fruit till they are seven or eight years old, but never any considerable quantity till they are treble that age, when they have formed large heads.

The fruit is used at two different stages of growth; when green, to pickle; and when ripe, to eat raw.

As a pickle, the young green walnut, when about half or near three-parts grown, before the outer coat and shell becomes hard, is a most excellent vegetable pickle; and for which purpose they are generally ready in July and August, observing that for this use they must be gathered by hand, chusing such as are as free from specks as possible.

The ripe fruit will be fit in the latter end of September and October, which, as before noticed, is commonly beat down with long poles, especially on large trees, for as the Walnuts grow mostly at the extremity of the branches, it would, in large trees, be troublesome and tedious work to gather them by hand. As soon as gathered, lay them in heaps a few days to heat and sweat, to cause their outer husks, which closely adhere, to separate from the shell of the nuts; then clean them from the rubbish, and deposit them in some dry room for use, covering them over close with dry straw, half a foot thick, and they will keep three or four months.

Walnuts are always ready sale at market, especially those of London, where at their first coming in, they are brought with their husks on, and sold by the sack, or bushel, but afterwards are brought clean, and sold both by measure and by the thousand.

Thus plantations of Walnut-trees are profitable in their annual crops of fruit while growing, and in their timber when felled.

Propagation of all the Sorts.

The propagation of all the sorts of these trees, is most commonly by planting the nuts, which grow freely in beds of common earth.

For those of the common Walnut intended for fruit-trees, the best varieties of nuts should be procured, such that are large, thin-shelled, and with the finest flavoured kernels; for although the finest sorts will vary or degenerate

nerate, yet by planting only the very best, there will be the greater chance of having a succession continued without much degeneracy.

Having procured the nuts at the proper season, when perfectly ripe, in their outer cover or husks, if possible; they should be preserved in dry sand until February, and then planted: at which time having the ground dug, draw drills two inches and a half deep, and a foot asunder, in which plant the nuts four or five inches apart, and cover them over with the earth; they will come up the same spring, and by the end of summer the young plants will be half a foot or more high, which, after having two years growth in the seed-bed, plant them out in the nursery; previously, when taken up, shorten their tap-roots, but preserve their tops entire, and plant them in rows two feet and a half asunder, and about eighteen inches distant in each row: here they are to remain a few years, training them with single stems, till five or six feet high, or a little more or less, then transplant them where they are finally to remain.

Those intended principally as timber-trees as well as to bear fruit, should be always planted out for good when from three to four or five feet high, or if the nuts were planted at once where the trees are designed to remain, without transplanting, they would assume a quicker and stronger growth.

The nuts of the second and third species, are annually sent hither from America, and may be had of most of the nursery-men and seed dealers; they commonly arrive in spring, and should be sowed as soon as possible after their arrival, in the same manner as directed for the common Walnut.

JUNIPERUS, Juniper, and the *Cedrus* and *Sabina*.

This genus furnishes beautiful ever-greens of the shrub and tree kind, for ornamental plantations, growing from three or four to thirty or forty feet high in different sorts, often branchy to the very bottom, and of pyramidal growth; closely garnished with very small narrow leaves, placed mostly imbricatum, remaining all the year; and dioecious flowers, of no beauty, succeeded by small berries.

Class and order, *Dioecia Monadelphia*.

Characters.] **CALIX**, male and female flowers on different plants; the males in a conical amentum, by threes, having broad scaly imbricated calices; and the females a

small three-parted cup placed on the germen. **COROLLA**, none in the males, and in the females three stiff permanent petals. **STAMINA**, three filaments, and three distinct antheræ. **PISTILLUM**, a germen under the calix of the females, three styles and simple stigmas. **PERICARPIUM**, a roundish fleshy berry, having three seeds.

In this genus is retained also several of the *Cedrus*, or Cedars; and the *Sabina*, or Savin, of former botanists, which they ranged as distinct genera, but are found to be only species of the *Juniperus*. There are several species, all of them, except the common Juniper, are foreigners, but all tolerably hardy, succeed in the open ground, and are great ornaments to our ever-green plantations.

The species are;

¹**JUNIPERUS Communis.**

Common Juniper. Of which there are the two following

Varieties.

Common Shrubby English Juniper.—Grows five or six feet high, branching closely from bottom to top; forming a very close bushy plant, thickly garnished with narrow, awl-shaped, acute-pointed, spreading leaves by threes; and small yellowish flowers in spring; succeeded, in the female plants, by purplish berries, ripening the following year in autumn.

This variety grows wild in England upon barren heaths and commons, where it produces abundance of berries; but is cultivated in gardens, and trained for an ornamental shrub, to encrease the variety in shrubbery plantations.

Swedish Juniper.—Grows ten or twelve feet high, very branchy the whole length, with the branches growing more erect, and leaves, flowers, and fruit like the former variety. Is a native of Sweden and Denmark.

²**JUNIPERUS Oxycedrus.**

Oxycedrus, or Spanish Juniper.] Grows ten or fifteen feet high, closely branched from bottom to top; short, awl-shaped, spreading leaves by threes, and small dioecious flowers, succeeded by large reddish-brown berries.

³**JUNIPERUS Thurifera.**

Greater Blue-berried Spanish Juniper.] Grows twenty feet high, or more, branching in a conic form, acute imbricated leaves by fours, and small dioecious flowers, succeeded by large blue berries.

⁴**JUNL.**

*JUNIPERUS *Virginiana*.

Virginia Cedar.] Grows thirty or forty feet high, branching from bottom to top, in a conic manner; small leaves by threes adhering at their base, the younger ones imbricated, and the old ones spreading; and dioecious flowers, succeeded by small blue berries.

*JUNIPERUS *Lycia*.

Lycian Cedar.] Grows twenty feet high, branching erectly, garnished with small oval, obtuse leaves, every where imbricated; and dioecious flowers, succeeded by large oval brown berries. Is a native of Spain and Italy.

*JUNIPERUS *Phœnicea*.

Phœnician Cedar.] Grows about twenty feet high, branching pyramidically; adorned with ternate and imbricated obtuse leaves; and dioecious flowers; succeeded by small yellowish berries. Is a native of Portugal.

*JUNIPERUS *Bermudiana*.

Bermudian Cedar.] Grows twenty or thirty feet high; has small acute leaves, by threes below, the upper ones awl-shaped, acute, and decurrent, by pairs or fours, spreading outward; and dioecious flowers, succeeded by purplish berries. Is a native of Bermudas.

*JUNIPERUS *Sabina*.

Sabina, or Savin-tree; Of which there are the following

Varieties.

Spreading Savin.—Grows but three or four feet high, with horizontal very spreading branches; short, acute-pointed, decurrent, erect, opposite leaves; and dioecious flowers, succeeded by blueish berries; but very rarely produces either flowers or fruit.

This variety is used in medicine; and it is said the juice of the leaves mixed with milk and honey is excellent for expelling worms in children; and a poultice thereof cures scald heads; the juice of it is also said to clear the face from freckles; and the farriers esteem it greatly for destroying worms in horses, it being a powerful operator that way; and its virtues are accounted excellent for many other disorders.

Upright Savin.—Grows eight or ten feet high, with upright branches, dark-green leaves, nearly like the former sort, and dioecious flowers, succeeded by plenty of berries.

Variegated Savin.—Having the ends of many of the the shoots and young branches

variegated with white, and the leaves finely striped, the whole appearing very beautiful.

All these species of *Juniperus* are very pretty ever-greens, of the tree and shrub kind, mostly of picturesque growth, branching out all around closely from bottom to top; all of them very closely garnished with leaves, which although in general very short and small, yet are so numerous and thickly set, that the plants appear every way very close and beautiful; and all the sorts are excellent furniture for all ornamental plantations, where they will have a fine appearance at all seasons of the year, as being always clothed with leaves; but as to their flowers, they have no beauty, except to the botanists for observation; and as to fruit, the common Junipers produce plenty, also some of the others; but the Cedars rarely furnish many berries in England; nor do the spreading Savin, though the upright kind often produce such plenty as to have a very agreeable effect on the plants.

They all succeed in the open ground, and will grow in any common soil and situation, in common with other hardy trees, though they are rather the most prosperous in a light sandy soil.

In disposing all these kinds of plants in the shrubbery plantations, good attention should be had to arrange them according to their degrees of growth, so as to exhibit a regular gradation of height, placing the low-growing sorts, such as the *Juniperus Communis*, and the Savin kinds, towards the front; and the other larger growers more backward in proportion to their several statures, placing all of them in assemblage with other ornamental shrubs and trees, principally of the ever-green tribe.

Some of the large-growing sorts may also be introduced into the forest-tree plantations; as in their native countries they afford excellent timber for many uses, more particularly the Virginia cedar, which also arrives to a considerable stature here, especially if the under branches are trimmed off occasionally while young, to promote their aspiring in height; they will grow very straight, with fine regular heads.

Most of these species of *Juniperus*, emit a strong aromatic balsamic odour, and abound more or less with a resinous juice of so exceedingly bitter quality, as to prevent the timber, when converted to economical uses, from being eaten and destroyed by vermin.

J U N

Propagation of all the Sorts.

The propagation of all the Juniper and Cedar kinds, is by seed; and the Savins principally by layers and cuttings; but may likewise be raised from the berries, if they can be procured; and the seeds of all the sorts are to be sowed in beds of common light earth, except the Cedar of Bermudas, which must be sowed in pots, to have shelter in winter.

The seeds of all the sorts may be had at most of the nurseries and seedsmen; observing that those of all such sorts which can be procured in autumn, should be sowed at that season, whereby they will more certainly come up the spring following; but those that are not sowed till spring, generally remain in the ground till that time twelvemonth, before they germinate or sprout, unless aided by a hot-bed. Some of the sorts, however, rarely produce much seed here: it is procured annually from the countries where the trees naturally grow, by the seedsmen, commonly arrives early in spring, and should be sowed as soon after their arrival as possible.

All the sorts, except the Bermudas Cedar, as before observed, are to be sowed in beds of light earth, in the full ground. Having dug the ground, and raked it fine, sow the seeds evenly on the surface, and cover them with fine earth half an inch deep. Those sowed in autumn, will many of them come up in April or May following; but the spring sowings will rarely appear till the following Spring. In either case, however, keep the beds clean weeded all summer; and those plants that are up, now and then watered. When they have had two years growth in the seed-bed, plant them out, in autumn or spring, in nursery rows, two feet asunder, there to remain till of due size for final transplantation into the shrubbery, &c.

The Bermudas Cedar, as above noticed, being tender, it should be sowed in pots or tubs of light earth, to be moved under a frame in winter to be sheltered from frost; and when the plants are a year or two old, plant them in separate small pots, to be sheltered also in winter three or four years, till they have acquired some size and strength, then turned out of the pots into the full ground where they are to remain, in a warm situation, where let them take their chance, though a shelter of mats for the first winter

J U S

or two during hard frosts will be of great service.

The season for transplanting all the sorts is either in autumn, October or November, or in March and early in April.

JUSTICIA, (*Adhatoda*) Malabar nut.

It consists of shrubby and herbaceous plants, of the Indies, for the green-house and stove, adorned some with fine large leaves, others with small narrow foliage, and all of them with monopetalous ringent flowers.

Class and order, *Diandria Monogynia*.

Characters.] CALIX, is small and acutely five-parted at top. COROLLA, is monopetalous and ringent. STAMINA, two awl-shaped filaments, and erect antheræ. PISTILLUM, a turbinate germen, slender style, and simple stigma. PERICARPIUM, an oblong bilocular capsule, opening with elastic force, and dart out their roundish seeds.

There are many species but not more than two common to the English gardens, both of them of the shrub kind for the green-house, viz.

¹JUSTICIA, *Adhatoda*.

Adhatoda, commonly called Malabar-nut.] It grows twelve or fifteen feet high, with a strong woody stem, branching out widely all around; large lanceolate oval leaves, placed opposite; and from the ends of the branches short spikes of white flowers, with dark spots, having the helmet of the corolla concave.

²JUSTICIA *Hyssopifolia*.

Hyssop-leaved Justicia, or Snap-tree.] Hath a shrubby stem, branching from the bottom pyramidally three or four feet high; spear-shaped, narrow, entire leaves, growing opposite; and white flowers, commonly by threes, from the sides of the branches; succeeded by capsules, which bursts open with elastic force, for the discharge of the seeds. Hence the people of India call it Snap-tree.

Both these species flower here in summer, but never produce fruit in these parts.

They are natives of India, so are tender and must be kept in pots of light rich earth, and placed in a good green-house in winter, or may be placed in a hot-house, particularly the second sort; though they will both live in the open air in summer, and in a warm green-house in winter, managing them as other shrubby exotics of that department.

The propagation of both sorts may be effected by layers and cuttings. The laying is per-

K A L

performed in spring, in the pots; and cuttings of the young shoots may be planted any time in spring or summer, in pots, and plunged in a hot-bed, or in the bark-bed in the stove, giving water, and occasional shade from the sun; they will readily take root.

IXIA, *Ixia*.

This genus consists of herbaceous, tuberous and bulbous-rooted flowery perennials for the pleasure-ground and green-house, growing a foot or two high, terminated by hexapetalous flowers.

Class and order, *Triandria Monogynia*.

Characters.] CALIX, oblong permanent spathæ. COROLLA, six oblong, spear-shaped, unequal petals. STAMINA, three short filaments, and simple antheræ. PISTILLUM, an oval triquetrous germen under the receptacle, erect style, and trifid stigma. PERICARPIUM, a roundish, three-cornered, trilocular capsule, having roundish seeds.

There are several species, the most material of which are:

*Hardy Kinds.*¹IXIA *Bulbocodium*.

Bulbous Italian Ixia.] Hath a small bulbous root; crowned by several narrow leaves; and very short flower-stalk, terminated by a large crocus-like flower, of different colours in the varieties.

Varieties.] With white and yellow flowers—with purplish and yellow flowers—blue and white flowers—white flowers—variegated flowers.

²IXIA *Chinensis*.

Chinese Ixia.] Hath a thick, tuberous, knotty root; upright jointed flower-stalk, two feet high; garnished with sword-shaped leaves a foot long; and the stalk dividing upward into forks; sustaining yellow red-spotted flowers, remote, in forked panicles; appearing in July and August.

K A L

*Tender Kinds.*³IXIA *Bulbifera*.

Bulb-bearing Ixia.] Hath a bulbous root; crowned with narrow leaves, six or eight inches long; and upright flower-stalks, a foot and a half high; garnished with leaves, bulbs growing at the joints; and terminated by sulphur-coloured flowers, placed alternate.

⁴IXIA *Crocata*.

Saffron-coloured Ixia.] Hath a bulbous, root; sending up sword-shaped leaves, near a foot long; and upright flower-stalks, a foot or more high; terminated by clusters of deep yellow flowers, arranged alternate, having each a large black spot at the base; flowering in May.

⁵IXIA *Africana*.

African Woolly-headed Ixia.] Hath a small bulbous root; sending up very narrow leaves; a short flower-stalk, three or four inches high; terminated by flowers collected into woolly heads.

The flowers of all these plants are composed each of six oblong petals, appearing in summer, and, in warm seasons, some sorts are succeeded by ripe seeds.

The plants are all permanent in root, but annual in leaves and stalk.

The two first species may be planted in the open borders; the second, however, being rather tender, it should have a warm situation; and some may be planted in pots to remove to shelter of a green-house or garden-frame in winter, in case those in the open ground should be killed by hard frost.

The three other species must be planted in pots of rich light earth, for moving into the green-house or garden-frame all winter.

All the sorts propagate plentifully by offsets of their roots, which should be taken off in summer at the decay of the leaves, &c.

K.

KALMIA, *Kalmia*.

Of this genus are two hardy evergreen shrubs, for the pleasure-ground, growing four or five feet high; adorned with

oval, and spear-shaped entire leaves, and monopetalous, five-parted, in close round bunches.

Class and order, *Decandria Monogynia*.

Characters.]

Characters.] CALIX, is small, five-parted, and permanent. COROLLA, is monopetalous, with a cylindric tube, and the limb divided into five roundish spreading segments. STAMINA, ten filaments, and simple antheræ. PISTILLUM, a roundish germen, slender style, and obtuse stigma. PERICARPIUM, a roundish quinquelocular capsule having numerous small seeds.

The species are ;

¹KALMIA *Latifolia*.

Broad-leaved Kalmia.] Hath a shrubby branching stalk, growing five or six feet high; oval, stiff, shining green leaves, placed irregularly; and corymbus clusters of pale-red flowers terminating the branches.

²KALMIA *Angustifolia*.

Narrow-leaved Kalmia.] Hath a shrubby stalk, dividing into many slender branches, growing four or five feet high; spear-shaped, stiff, shining-green leaves, placed irregularly; and corymbus clusters of bright-red flowers from the sides of the branches.

Both these shrubs are beautiful ever-greens, natives of America, but hardy enough to succeed any where in the open ground in this country.

They flower in June or July, the flowers collected into round, close-fitting, corymbus clusters; each flower is of one petal, tubular below, and five-parted and spreading above; and those of both the species are very ornamental, but they are rarely succeeded by ripe seeds in England.

These shrubs are elegant furniture for ornamental plantations, and should be placed towards the front of the most conspicuous shrubbery compartments.

Their propagation is by seed, suckers, and layers.

By Seed.—This arrives from America in spring: sow it either in beds of light ground, or in pots or boxes of light sandy earth, half an inch deep, and plunge them in an easterly border till spring following; and then, if the plants do not come up before, if the pots are plunged in a hot-bed it will forward them greatly; but innure them betimes to the full air all summer; and in winter give shelter from frost, and when two years old, plant them in separate pots, to move to shelter for two more winters, then let them be planted out in the full ground.

By Suckers.—The plants, after a few years standing, send up suckers in tolerable plenty, which should be taken off in spring, and planted in nursery rows for two, three, or

more years, to acquire strength, then transplanted for good.

By Layers.—In autumn lay some of the young shoots of last summer, and they will be rooted in a year or two.

KÆMPFERIA, *Galangale*.

This genus consists of low, herbaceous, flowery perennials of India, for the stove, adorned with radical, oval, and spear-shaped leaves, and monopetalous, tubular, six-parted flowers.

Class and order, *Monandria Monogynia*.

Characters.] CALIX, is obsolete, and placed above the germen. COROLLA, is monopetalous, with a long slender tube below, and six-parted above; three of the parts are spear-shaped, two are oval, and the lowest is divided into two obcordate segments. STAMINA, one membranaceous suboval filament, and linear anthera, growing along the filament its whole length. PISTILLUM, an oval germen, simple style, and obtuse stigma. PERICARPIUM, a roundish trilocular capsule, having many seeds.

There are but two species, both of low growth, and acaulous, i. e. having no stem; the leaves and flowers rising directly from the root annually.

The species are ;

¹KÆMPFERIA *Galanga*.

Galangale.] Hath tuberous, thick, oblong, fleshy roots; crowned with oval, close-fitting leaves, by pairs, four or five inches long, without foot-stalks, and between them close-fitting white flowers, with purple bottoms, growing singly.

²KÆMPFERIA *Rotunda*.

Round Kæmpferia.] Hath thick, fleshy, swelling, roundish, clustering roots; sending up spear-shaped leaves, six or eight inches long, near half as broad, on upright foot-stalks; and between them, immediately from the root, rise whitish flowers, tinged with green, red, yellow, and purple centres.

Both these are perennial in root, but the leaves rise annually from it in spring, and decay in winter.

They flower in summer; each flower is of one petal, tubulous below, but plain above, and divided into six parts; continue three or four weeks in beauty, but are never succeeded by seeds in England.

Both these plants must be potted in light rich mould, and always kept in the hot-house, giving plenty of water in summer, but more sparingly in winter. They are propagated by

U u u

parting

parting their roots in spring, just before they begin to push forth new leaves.

KIGGELARIA, *Kiggelaria*.

There is but one species, an ever-green shrub of Africa, retained here in green-house collections, for variety; and is a dioecious plant.

Class and order, *Dioecia Decandria*.

Characters.] CALIX, dioecious flowers, having monophyllous, five-parted cups. COROLLA, five spear-shaped, concave petals. STAMINA, ten small filaments, and oblong antheræ. PISTILLUM, a roundish germen, five styles, and obtuse stigmas. PERICARPIUM, a globular, rough, unilocular capsule, having angular seeds.

The species is;

KIGGELARIA *Africana*.

African Kiggelaria.] Hath an upright woody stem, and purplish branches, growing fifteen or eighteen feet high; oblong, sawed, alternate leaves; and dioecious, greenish-white flowers, in clusters from the sides of the branches; succeeded by globular rough fruit, the size of cherries, containing the seeds, which seldom ripen here.

This plant must be potted in rich garden-mould, and placed among the green-house plants, to have shelter in winter, managing it as other woody kinds.

It is propagated by seeds, layers, and cuttings, though both layers and cuttings root sparingly.

Sow the seed in pots, and plunge them in a hot-bed, and when the plants are come up three or four inches high, plant them in separate small pots, plunging them also in the hot-bed till fresh rooted, then harden them to the full air the rest of summer.

Layers should be made in summer of the young shoots of the year.

And cuttings of the young shoots may be planted in spring in pots, and plunged in a bark-bed or other hot bed, and if close covered with a hand-glass, they will more readily succeed.

KITCHEN-GARDEN, a principal district of garden-ground allotted for the culture of all kinds of esculent herbs and roots for culinary purposes, &c.

A Kitchen-garden may be said to be the most useful and consequential part of gardening; since its products plentifully supply our tables, with the necessary support of life, for it is allowed that health depends much on the

use of a proper quantity of wholesome vegetables, so that it is of much importance for every person possessed of a due extent of ground to have a good Kitchen-garden for the supply of his family. This garden is not only useful for raising all sorts of esculent roots and herbs, but also all the choicer sorts of tree and shrub-fruits, &c. both on espaliers, wall-trees, and standards; as the annual cultivation of the ground by manuring, digging, hoeing, &c. necessary in the culture of the esculent herbs, also greatly encourages all sorts of fruit-trees, preserves them in health and vigour, so as always to produce large and fair fruit: for which reason, in the Kitchen-garden should always be planted the choicest sort of fruit-trees, particularly for walls and espaliers; likewise some standards, if set a considerable way asunder, so as not to shade the under-crops too much; and when the trees are judiciously disposed, there will be almost equally the same room for the crops of herbaceous esculents as without trees; so that this garden may be reckoned both as a Kitchen and fruit-garden.

As to the place of disposition of this garden respecting the other districts, if it is designed principally as a Kitchen and fruit-garden, distinct from the other parts, and there is room for choice of situation, it should generally be placed detached entirely from the pleasure-ground; also as much out of view of the habitation as possible, at some reasonable distance, either behind it, or towards either side thereof, so as its walls or other fences may not obstruct any desirable prospect either of the pleasure-garden, park, fields, or the adjacent country; having regard, however, to place it, if possible, where the situation and soil is eligible, as hereafter illustrated; and if its situation is unavoidably such as to interfere with the pleasure gardens, so as its walls may be thought disagreeable to view, they may be shut out from sight by intervening plantations of shrubs and trees.

But as in many places they are limited to a moderate compass of ground, in others have scope enough, and require but a moderate extent of garden; that in either case, have often the Kitchen, fruit, and pleasure-garden all in one; having the principal walks spacious, and the borders next them of considerable breadth; the back part of them planted with a range of espalier fruit-trees, surrounding the quarters; the front

front with flowers and small shrubs; and the inner quarters for the growth of the Kitchen-vegetables, &c.

The proper Situation, Soil, Water, Extent, &c.

As to situation, on this head we can only observe in general, that both high and low situations, if the soil is proper, will produce good crops of esculent herbage and fruits; though a moderately low situation, by being less exposed to the influence of cold and violent winds, may suit winter and early crops, both of herbs and trees, better than high-lying ground, provided, however, it is moderately dry, and not too retentive of moisture in winter. A situation having a moderate slope is very eligible for this purpose, as in such a spot there will not be any danger of water standing, nor of being too wet at any season; and if it slopes toward the South, it is a most desirable situation, as it will not only be better defended from the cold northerly winds, but its exposure or aspect inclining to the sun, we may always expect to have the earliest crops; or if, when the situation allotted for this garden is in some parts high, or a little sloping, and others low and moist, it may be some advantage, as the high or sloping ground will suit for early crops, and for wintering several sorts of plants that are impatient of copious moisture in that season, such as lettuce, &c. and the low ground will be eligible for late summer crops, as peas, beans, cauliflowers, transplanted lettuce, and several others. However, as to choice of situation and soil, this is practicable in large estates; but where persons are limited to a moderate space, they must be content with such as nature affords; observing in this case, that if the natural soil is of a proper temperament and depth, we need not be under any great anxiety about the situation, if it is moderately dry, and not apt to be overflowed in winter; even in that case, it may be remedied, or greatly helped, by digging two or three long narrow canals, and from these some underground hollow drains, the earth from which will help to raise the contiguous ground higher, and the water in the canals will be convenient for watering the plants. Remark that a situation too wet in winter should be guarded against as much as the nature of the place will admit, for in such land

we can never have early crops, nor will the fruit-trees be prosperous.

With respect to soil, (see EARTH); the soil for a Kitchen-garden, of all others, requires to be naturally good, of depth enough for the growth of the large perpendicular esculent roots, as carrots, parsneps, red beet, horseradish, &c. also for the growth of fruit-trees, a very material article; so that the proper soil for these general purposes, should, if possible, be from about a foot and a half to three feet deep or more; but much less than a foot and a half depth will be a great disadvantage; so much depends upon the quality of the soil for a Kitchen and fruit-garden, that where there is scope of ground to chuse from, we cannot be too cautious at first in fixing on a proper spot, where the soil is good, and depth enough, as above, before gravel, clay, chalk or other bad soils are come at, which should always be more particularly attended to when designed to furnish the ground with a choice collection of fruit-trees, either for the walls, espaliers, or standards; for without a due depth of good earth, these will neither bear well, nor be of long duration.

Different sorts of soils are met with in different parts, as loamy, clayey, sandy, &c. A loamy soil either of a brown or black colour, is the best that can be for this purpose, more particularly a light sandy hazel loam, which always works pliable at all seasons, not apt to be too wet and cloggy at every shower of rain, nor bind in dry hot weather; this soil, however, although the most common superficial earth in this country, is not common to all parts. A clayey, strong, stubborn soil is the worst of all earths, and must be mended by sandy materials and coal ashes. A sandy soil is common in many places, which if of a very light sharp nature, it must be fertilized by plenty of rotten dung; and strong earths where they can be easily procured.

It is observable that ground which constantly produces good crops of corn and grass, is also proper for the growth of all esculent herbs and fruit-trees.

Chuse, however, the best soil you can, according to the situation and extent of your ground; and if it happens to prove unfavourable, art must assist; for if it is of a light sandy nature, it may easily be mended, by adding store of any kind of rotten dung; and if of a very light, sharp, hungry temperament,

ment, earths of stronger substance, such as loam, and the like, if it can be easily obtained, must be added occasionally along with plenty of dung, working the whole with the natural soil of the garden; and should your garden be of a clayey, cold, damp nature, add light materials, such as any light sandy soils; nothing is more proper than plenty of coal-ashes, for opening and warming all tough, stubborn, cold soils; and these may be always procured in plenty almost every where, at an easy expence. See COMPOST, EARTH, &c.

Water is a very essential article in a Kitchen-garden in summer, to water all new transplanted plants, and others that cannot subsist without a due supply of moisture during the drought of that season; therefore, where practicable, one or more reservoirs of of water should be contrived in the most convenient part of the ground, either in basons or narrow canals, and supplied with water from some contiguous spring, river, brook, pond, well, &c. See WATER.

The necessary space of ground proper for a family Kitchen-garden, may be from about a quarter of an acre to six or eight, according to the extent and demand of the family, and the expence the proprietor would chuse to bestow on the making and general culture. A Kitchen-garden of an acre will nearly employ one man, especially if it be furnished with wall and espalier trees to manage, and so in proportion to a garden of smaller or larger extent, a garden of the above size will produce a prodigious plenty of esculent herbage and fruit, sufficient at least for a family of ten or fifteen persons; but on large estates, where the family is considerable in proportion, three or four acres of Kitchen-garden may be necessary; and some very large families have them of six or eight acres extent.

Fences for inclosing the Ground.

With respect to fences for inclosing the ground, it is most necessary to have an effectual fence of some sort around the Kitchen-garden, both for security of the produce, and to defend tender and early crops from cutting winds, and if wall-fences are used, they are also of the greatest utility for training wall-trees, for producing the more delicate kinds of fruit, which do not acquire perfection in this country without such aids.

Previous to fencing the ground, the proper shape or form for the garden is to be considered; the most eligible form for a Kitchen-garden, is that either of a square, or oblong square; but the figure may be varied, according as that of the situation admits; keeping, however, as near as possible to the square, or oblong form, especially if the ground is to be fenced with a wall for training fruit-trees; no other shape answers so well for that purpose; for trial having been made of circles, ovals, semi-circles, angles, &c. but none succeeded near so well as the square form, with the walls built entirely straight.

Different sorts of fences are used for inclosing this ground, as walls, paling, and hedges.

But where wall-trees are intended, the best sort of fence is a wall of brick or stone; but brick walls are considerably the best for training trees upon, for the joints of the brick-work being at short regular distances, affords frequent opportunities for nailing the branches; besides, the bricks themselves will also often admit of the nails being driven into them; so that against brick-walls we may readily train trees in the most regular manner; but in default of bricks, and where stone-walls are intended, the stones should be as regular as possible, and not too large, especially in the front of the walls, that the joints may be at small distances for the convenience of nailing, otherwise there will be an absolute necessity of having a treillage of wood-work erected against the walls for nailing the branches to. See TREILLAGE.

Sometimes, to save expences in building brick or stone-walls, boarded fences, or paling is used, both as fences, and for training fruit-trees upon. When such fences are intended for trees, the boarding should be tongued and closely joined, edge to edge, and so as to form a plain or even surface, for the commodious training the branches.

In gardens where no wall-trees are intended, a hedge, or bank and hedge is a very proper fence, which may be so trained as to form both an effectual fence against men and beasts, also to shelter particular parts of the ground for raising early crops; and a hawthorn hedge is the most proper sort, though other sorts may be used. See HEDGES.

No fencing, however, for a Kitchen-garden, where intended to have wall-trees, is equal to brick or stone walls, which is considerably

siderably stronger, warmer, and more durable than paling fences, and their natural warmth, together with their reflection of the sun's heat, is the most effectual for the growth and ripening the more delicate kinds of fruit; but the brick walls are the warmest of all.

Either of these kinds of wall or paling-fences for fruit-trees, should, where there is scope of ground, be so contrived as to have both sides occupied with trees, which is effected by having a slip of ground taken in all round the outside of the wall, or as far as may be convenient, about ten, twenty, or thirty feet wide, or more, inclosed with a bank and hedge (see HEDGES), or with any kind of paling, fencible against men and beasts; which part, besides its utility in affording an opportunity of planting the outside of the wall, it will also be an addition to the Kitchen-ground, as it will serve for raising many sorts of Kitchen-esculents, and is often used as a sort of nursery, both for herbaceous and woody plants.

And in large gardens, where a great supply of wall-fruit is required, some cross-walls may be run along the garden, at an hundred feet or more asunder, but if more the better; both sides of which may also be planted with trees, as observed of the boundary-wall.

The proper height for the walls, is from about eight to ten or twelve feet, but ten feet height will do tolerable well for most sort of trees, provided you plant the trees at distance enough to have room to spread their branches horizontally each way; the walls, however, should never be less than eight feet high. See WALLS.

Hot-walls for forcing by fire-heat, &c. is often erected in large Kitchen-gardens; for an account of which, see FORCING FRAME and WALLS.

Preparing and laying out the Ground.

The whole ground should be regularly trenched two spades deep; observing if the soil is poor, or of bad quality, and wants amendment, either of dung, or any of the materials before mentioned, respecting the soil, it must be previously added, and trenched in betwixt the bottom and top spits, so as next year, when it comes to be digged again, the compost being well-rotted, will be worked up, and mixed with the natural soil. See DIGGING and TRENCHING.

Do not omit enriching and improving the borders for the wall and espalier-trees, by adding a considerable portion of rotten dung; and if the natural soil is not good, add also, if possible, some good loamy earth from the surface of a field or common, either to the whole, or rather than fail, a few barrows-full to each place where the trees are to stand; and improve the rest afterwards by degrees at your convenience.

The ground must be divided into compartments for regularity and convenience. A border must be carried all round the boundary-walls, not less than four, but if six, eight or ten feet wide, the better, for the benefit of the wall-trees, that their roots may have full scope to run in search of nourishment, for they generally run as far under ground as their branches extend in length, and by the annual digging and stirring the ground about them to some considerable breadth, greatly encourages the trees; hence the utility of having a broad border under the walls; next to this border a walk should be continued also all round the garden, of due width, as mentioned below; then proceed to divide the interior parts into two, four, or more principal divisions and walks, if its extent be large; first a straight walk should run directly through the middle of the garden; and another, if thought necessary, may be directed across the ground, intersecting the first; and if the garden is of some considerable length, two, three, or more, such cross walks may be necessary; the width of the walks may be from about five to ten or twelve feet, in proportion to the extent of the garden; and each of the quarters should be surrounded with a five or six feet wide border, and range of espaliers planted along towards the back-part of each border, so that every quarter will be inclosed with an espalier.

I would not, however, by any means advise dividing small or moderate-sized gardens into too many walks and small quarters, especially if they are to be surrounded with espaliers, which would render them too confined for the proper growth of culinary herbage; besides it would be wasting too much of the ground in walks.

In one of the quarters a place should be allotted for the melon-ground; that is, a place for making the hot-beds for raising early cucumbers, melons, and other tender plants, fixing on a spot for this purpose, full to the sun from rising to setting, sheltered as much as possible from

from the northerly winds, and conveniently situated for bringing in the dung for the hot-beds.

This place, if not so situated as to be sheltered by the walls, or other fences of the garden, will be of much advantage to inclose it with a close fence, either a reed-hedge, or paling; serving both to break off the winds, and by having a door to lock, will preserve your crops more secure; these fences may be six or seven feet high in the back or north side, with both the side fences sloping gradually to about five feet height in front; which should always be lowest to admit the sun freely. See MELONARY.

With regard to the borders and walks of of this garden, the outer borders adjoining the walks should be neatly formed, and the edges made firm and straight, and the walks gravelled, or laid with other dry materials.

The edges of the borders are frequently planted with box, &c. especially in gardens where the Kitchen and pleasure-ground are all in one; sometimes part are edged with undershrubby aromatic herbs, as thyme, favory, hyssop, and the like; but unless these are kept low and neat, they appear unsightly; some, however, use no planted edgings at all in proper Kitchen-gardens, only have the edge of the border made up even, treading it firm that it may stand, then cut it straight by line; sometimes along the top of this edging is planted a row of strawberries, a foot or fifteen inches asunder, they will bear plentifully, and have a good effect; observing to string them several times in summer, to preserve them neat and within due compass. See FRAGARIA.

The walks should principally be laid with gravel, or good binding sand, or nothing better than road-stuff, i. e. the wet soil of turnpike-roads, raked and shovelled up by the road-people in moist weather, in heaps; which being the ballast or stones used in repairing the roads, ground to pieces, and after having lain some time to dry, then brought in, it will form exceeding good walks for the Kitchen-garden; or, for want of either of the above materials, may use coal-ashes, which, if the black colour can be dispensed with, will make a tolerably firm dry walk.

Sometimes grass-walks are used, but these are rather improper for general use in Kitchen-gardens, especially in such parts of the garden where wheel-barrows are obliged to come often, which would cut and greatly deface

them; besides, they are apt to be wet and disagreeable in all wet weather, and in winter; but if any are intended for variety and summers walking, they should be only in some high dry part of the garden, and never let them be general, for besides the afore-mentioned inconveniences, they are apt to harbour slugs and other crawling vermin, to the detriment of the adjacent crops.

The wall trees should be planted at from fifteen to twenty feet distance, according to the sorts. For peaches, nectarines, plums, and cherries, fifteen or eighteen feet is the proper distance; but for pears twenty feet is requisite: observing to plant the choicer and more delicate sorts on the best exposures, so as to have the most sun, as is expressed under their proper articles. Where practicable, always plant both sides of the wall; and if you would have the walls covered as soon as possible, if the walls are high, may plant first dwarfs as the principal furniture, then half standards and full standards alternately between the dwarfs; and whilst the dwarfs cover the lower part, the standards furnish the upper: but are to be afterwards taken away by degrees as the dwarfs grow up. See WALL-TREES.

The espaliers should be planted in one range round each quarter, about five or six feet from the outer edge of the border, and from about fifteen to twenty-five feet asunder, according to the sorts of fruit-trees you plant. See ESPALIERS.

Within the espaliers in the quarters, you may plant some standard fruit-trees of the choicer sorts, but at thirty or forty feet each way distant, that they may not shade the ground.

Likewise in the quarters may be planted the small kinds of fruit-shrubs, as gooseberries, currants, and raspberries, in rows so as to divide the quarters into breaks of twenty or thirty feet wide, or more, placing the bushes nine feet asunder in each row, and if they are kept somewhat thin, and spreading the way of the rows, in the manner of an espalier, they will not incumber the ground, and will bear very plentiful crops of large fruit. See their *Culture*.

In many places, however, as we formerly noticed, there is but a small compass of ground, or so limited as to be obliged to have the Kitchen, fruit, and pleasure-ground all in one, or at least often all within the same general inclosure; in which cases, if any part of the ground is required for ornament,

ment, a portion of it next the house, may be laid out in a lawn or grass-plat, bounded with a shrubbery; beyond which have the Kitchen ground, separating it also from the other with shrubbery compartments: the Kitchen-garden may also be laid out with ornamental walks and borders, having a broad border all round next the walls; and next this, a walk from five or six to ten feet wide, carried all round the garden; another directly through the middle; and next the walks have a border of six or eight feet wide, carried round each quarter or principal division; which border, if made sloping from the front to the back-part, will appear better than if quite flat; planting a range of espalier fruit-trees along the back of the border, so as immediately to surround the quarters, allotting the outside of the border for flowers, and small flowering shrubs, having the edge planted with box or thurst; and the walks neatly laid with gravel, or other materials before mentioned; the inside within the espaliers to be the Kitchen-ground, dividing it, if thought necessary, by rows of gooseberry, currant, and raspberry plants.

But when necessary to have the whole space of the Kitchen-garden employed for real use, no ground should be lost in ornamental borders and walks: have a border all round the boundary-fence, four or five feet wide, except the south borders, which should be seven or eight feet broad, because of its great use for raising early crops; and have a walk round the garden, not more than a yard wide; allowing the same width for the middle-walks, or so as to admit of wheel-barrows passing to bring in the manure, &c. and may either have a four feet wide border all round each quarter, next the walks, or not, as you shall think proper; laying the walks neatly with any gravelly materials, or with coal-ashes, so as to have dry walking, and wheeling with a barrow in all weathers.

General Culture of the Ground.

With respect to the general culture of the Kitchen-garden; it consists principally in a general annual digging; proper manuring; sowing and planting the crops properly; keeping the ground clean from weeds; and watering the crops occasionally in summer.

As to digging; a general digging must be performed annually in winter or spring, for the reception of the principal crops: also as

often as any new crops is to be sowed or planted; remarking that the general digging for the reception of the main crops in spring, I should advise to perform it always by trenching either one or two spades deep, besides the paring at top, though, except for some deep-rooting plants, as carrots, parsneps, &c. one spade depth may be sufficient for common trenching, unless on particular occasions, to trench as deep as the good soil admits, to turn the exhausted earth to the bottom, and the fresh to the top to renew the soil. However, the trenching only one spade deep will much more effectually renew the soil than plain digging; and by paring the top of each trench, two or three inches deep into the bottom, all seeds of weeds on the surface, are thereby buried so deep, that they cannot grow; and I should likewise advise that the general digging be performed principally in winter, or early in spring; but would be much the better if some considerable time before the season for putting in the crops, that the ground may have the advantage of fallow, to meliorate and enrich it; and always let the ground be trenched in rough-ridges, that it may receive all possible benefit from the sun, air, rains, frost &c. as it is soon levelled down for the reception of seeds and plants. Plain digging, however, may be sufficient for slight crops, especially in summer or autumn: after the ground has been trench-digged in the general winter or spring digging. See DIGGING and TRENCHING.

As to manure, any kind of dung, or compost of dung and earth is proper; and if this could be suited to the nature of the soil, it might be the greater advantage; that is, for ground of a strong, heavy, cold nature, have for manure, a compost of well-rotted dung, ashes, or any sandy earths, and if light sandy ground, have the moistest sort of dung, and heavy earths; see COMPOST, &c. Though any kind of well-rotted dung will suit as proper manure for almost every soil, but none better than the dung of old hot-beds, which is the most common manure for Kitchen-gardens, it being horse, or stable-dung, first used in hot-beds, where it becomes rotted to a buttery temperament, of an extremely enriching quality, and suits almost all kinds of soil and plants; but well-rotted neats-dung is also very good, particularly for light grounds, or a compost of every kind, as horse-dung, neats-dung, hogs-hung, farm-yard dung, or mulch, ashes, lime-rubbish, saw-

law-duft, rotten tan, having lain together till well rotted, will make excellent manure. See COMPOST, DUNGS, &c.

The manuring, or dunging the ground, may be necessary every year or two, for all crops being of an exhausting nature in every foil, the vegetative vigour of the soils must be supported accordingly by a proper application of manure; but once every other year, however, the ground in general will want amendment; tho' where there is plenty of dung, give it as far as it will go every year, especially for the principal crops, such as onions, cauliflowers, cabbages, &c. for as the different crops exhausts the foil, the addition of dung fertilizes and renews it; which when duly applied in proper quantities, the various crops will not only be much finer, but arrive to earlier perfection than in poor starved ground.

All manuring should generally be performed in winter or spring, to be dug in at the general annual digging; taking opportunity of frosty or very dry weather to wheel in the dung for the principal manuring, as it may then be performed more easy and clean without clogging, or spoiling the walks, or tearing up the ground; laying it in heaps by barrows-full at equal distances; afterwards spread it evenly, and dig it in one spade deep, as directed under the articles DIGGING and DUNGS.

In regard to cropping the ground, the proper situation for, and method of raising the different plants is fully exhibited under their respective articles; we will therefore only hint here, that it is eligible to allot the driest, warmest, and most sunny situation for the early crops, and the other parts for the main crops.

The borders under the south walls are proper for raising the earliest plants, as early peas, beans, radishes, spinach, lettuce, carrots, small sallad-herbs, kidney-beans, &c. The east and west borders for succession of early crops; and the north borders, which being shady and cool, serve for raising, and pricking out many small plants, slips, and cuttings in summer; though all these borders in every exposure may be made useful at all seasons. The borders next the espaliers is proper for crops of small plants at all seasons of the year, as lettuce, endive, spinach, small-sallad herbs, strawberries, and several others, both to stand, and for transplantation; and by keeping all the borders constantly well furnished with various esculents, disposed ac-

ording to their different growths; they, besides their usefulness, effect a delightful variety.

The borders, however, under the walls are by most authors strictly prohibited from the growth of culinary plants, on a supposition of their robbing the trees of nourishment; but as the south borders being so valuable for raising many early crops, such as radishes, lettuces, spinach, small sallad-herbs, carrots, peas, beans, kidney-beans, &c. they should not be lost; in short all the other borders will be extremely useful in their turn; and when the borders are properly manured every year or two, I never found any material inconvenience arise to the trees. Peas and beans are particularly forbid to be growed on these borders, it is probable they might be better without them; but if only the lower growing sorts are cultivated, and these in wide rows, and not too close to the trees, there will be but little danger of their being injured by the crops, especially as above hinted, if care is taken to renew the foil with plenty of rotten dung.

In the internal parts, called the quarters, should always be raised the larger principal crops, such as cabbages, cauliflowers, broccoli, coleworts, peas, beans, kidney-beans, onions, leeks, carrots, parsneps, beet, potatoes, turneps, artichokes, celery, general crops of lettuces, spinach, horse-radish, &c.

As many of the esculent plants succeed best in rows, such as peas, beans, cauliflowers, and all the cabbage kinds; transplanted lettuces, endive, potatoes, artichokes, Jerusalem-artichokes, celery, and some others, particular regard is requisite, that the rows are at a proper distance for the plants to have full scope to grow, as directed for each sort under their proper heads; and would advise that all the tall growing sorts, as peas, beans, kidney-beans, &c. have their rows ranging south and north, if possible, that the sun may shine on each side of the rows in its turn, as well as on the ground between the rows; both of which is of more advantage to the crops than may be generally imagined, for when the rows range east and west, one row shades another, so that when the plants grow up, they cannot all receive an equal benefit of the sun and air.

The great art in cropping a Kitchen-garden, is to make the most of every part of the ground, where necessary, by having every part

part well occupied, and as many crops annually as possible; the Kitchen-gardeners about London are very expert at this; they crop their ground so full, in such regular order, often several crops coming forward at a time in the same ground, so contrived according to the growth of each sort, that as one crop is going off, another is coming on ready to succeed it, and after that another; so that the ground is often in full crop great part of the year; the method of which is generally hinted in the culture of the respective sorts under their proper heads.

With regard to the methods of sowing and planting the different crops, some are sowed in drills, some by broad-cast on the surface, and the seeds either raked in, or the earth spread or sifted over them; and as to planting out the different plants, it is most commonly done by dibble, and some sorts in drills or trenches, as practised for asparagus; see DRILL-SOWING, SOWING-SEED, PLANTING, TRANSPLANTING, DIBBLE, HOE, &c.

Destroying weeds is a most necessary culture in the Kitchen-garden, and which must be very particularly attended to in spring and summer, for the success of the crops greatly depends upon that work; it may be performed both by hand and hoe, occasionally; hand-weeding is proper for all close-growing small plants, that either do not require thinning at all, or are only to be thinned by degrees; but by hoeing, in many cases where the plants stand wide in rows, the broad hoe must be applied, both as the most expeditious method of killing the weeds, and the most effectual for the benefit of the plants, by stirring the earth about them; likewise small hoeing is effectual for many small plants that require thinning, and are designed to be thinned either in part, or hoed out at once to their due distances, such as onions, carrots, parsneps, beet, turneps, &c. see HOEING. Observing in either mode of destroying weeds, always proceed to it time enough before the weeds begin to spread much, or are above an inch high, then the work may be performed with ease and expedition, and to the great benefit of the crops, by having the weeds timely destroyed; always chusing dry weather for destroying weeds by hoe; and in hoeing between plants in rows, such as peas, beans, kidney-beans, cabbages, cauliflowers, &c. always in the first and second hoeing draw a little earth up about their stems or shanks, which

will greatly strengthen the plants, and forward their growth.

The utmost attention is necessary never to suffer weeds to stand to perfect their seeds in any part, whether in crop or vacant, or on dung-hills, or compost heaps, as they would lay the foundation of several years trouble to extirpate them, for as in digging or hoeing the ground, some of the seeds would be buried near the surface, others much deeper, at every time of stirring the earth a fresh crop of weeds would arise from the same seeds, which verifies the saying, "One year's feeding, makes seven years weeding."

When weeds, however, are unavoidably suffered to grow large, or greatly advanced towards seeding, and are pulled up, or hoed down, let them, if possible, be carried off the ground, as many sorts will often flower and perfect their seeds as they lie, particularly the downy-seeded kinds.

And with respect to root-weeds, i. e. those with perennial roots, such as bear-bind, couch-grass, &c. the roots of which, and all others particularly of the like creeping growth, should be carefully picked out, at every time of digging the ground, for the least bit will grow and greatly increase; and in spring or in summer, as often as they shoot above ground, should be pulled up, or where the hoe can come, deeply hoed, which if often repeated in dry weather, will greatly diminish them.

Watering the Kitchen-garden is only necessary in warm dry weather, to particular plants, more especially to all those newly transplanted; this in particular should never be omitted, where practicable, for by giving each new-set plant directly some water, it settles the earth close about their roots, they sooner set to growing freely, and establish themselves firmly; and in hot dry weather, the watering should be repeated every day or two for a week, till the plants have taken new root, and set to growing afresh. Watering is also often requisite in dry weather in the latter part of spring and during the summer season, to beds of new-sowed small seeds; also after they come up, if the dry hot weather continues. Some sorts of plants require continued occasional waterings throughout the spring and summer seasons, such as all plants in hot-beds, as cucumbers, &c. as directed under the respective articles. In performing the watering, that for new transplanted plants

in wide rows, is commonly performed with the rose, or the head of the spout of the pot off, giving it only just about each plant; though if all the ground is occasionally watered, it will be the more beneficial to the plants. However, where the plants stand close, either transplanted, or seedlings in the seed-bed, the watering should be performed with the head of the pot on, giving it all over the plants, ground and all; observing in watering beds of small seeds, or small seedling plants, not to water too heavy or hastily, lest it wash the seeds or plants out of the ground.

All general watering in summer, in hot sunny weather, should be performed principally in a morning or afternoon, that the moisture may have time to soak to the roots of the plants before it is exhaled by the sun's heat.

Neatness should also be observed in the Kitchen-garden as well as in the pleasure-ground, though not with that elegance as necessary in the latter; only a common useful neatness; for a well kept Kitchen-garden is to many as agreeable to walk in as the finest flower-garden; keep, therefore, all the walks particularly, and the principal outward borders clean from weeds, and all manner of rubbish, not suffering the decayed useless stalks and leaves of plants to remain; the same should also be observed of the quarters or internal divisions, clearing off all decayed cabbage-leaves, decayed peas and bean-stalks, artichoke-leaves, and other large rubbishy matter, which, besides their littering appearance, some sorts, such as the decayed leaves of all the cabbage kinds, artichokes, &c. are apt to emit disagreeable smells, and harbour slugs and other crawling vermin; so should always be cleared off, especially in gardens where company often walk.

And as crops are cleared off the ground, always broad-hoe it to cut up all the weeds, and if the weeds are large, it is proper to rake them off, especially if it is like to be wet weather, but if dry and sunny they will soon die.

In autumn and winter as the ground becomes vacant from crops, manure such as require it, and trench the ground up in ridges, previous to spring cropping, for it greatly improves all ground to lie thus exposed to the weather some months before it is sowed or planted.

Kitchen-garden Plants.

KITCHEN-GARDEN PLANTS. Having given directions above for the making and general culture of the Kitchen-garden, a list of the principal plants necessary to furnish such gardens, will, we presume, be proper in this place; which notwithstanding their being all fully treated of under their respective genera, yet by collecting them into one point of view, with short hints of their method of propagation, will greatly assist the memory of every one, in furnishing his garden at the proper season.

We will exhibit each sort under its generic botanic name, viz.

AGARICUS campestris.—Field agaric, or mushroom. Propagation by spawn of the root, running in lumps of earth or dung. Autumn the proper season.

ALLIUM, garlick, onion, leek, &c. The sorts are:

ALLIUM sativum, manured garlick, of which there are—large white garlick—red garlick. Propagation by the cloves of the root.

ALLIUM scorodoprasum, rocambole. Propagation by the root and bulbs from the stalk.

ALLIUM cepa, the onion—common oval Strasburgh onion—great oval Portugal onion—flat white Spanish onion—flat red Spanish onion—silver-skinned onion—bulblefs-rooted Welsh onion. Propagation of all by seed annually.

ALLIUM schoenoprasum, chives, or cives. By dividing the roots.

ALLIUM ascalonicum, escalot, or shallot. By off-sets of the root.

ALLIUM porrum, the leek—broad-leaved London leek—narrow-leaved leek. By seed annually.

ANETHUM, dill, &c. consisting of the following species.

ANETHUM graveolens, common dill. By seed annually.

ANETHUM fœniculum, fennel—light-green-leaved fennel—dark-green fennel—sweet-seeded fennel. By seed, also, by slipping the old roots.

ANETHUM finochia, or Italian fennel. By seed annually.

ANGELICA sativa, or *archangelica*—common angelica. By seed annually.

APIUM, parsley, celery, &c. consisting of the following sorts:

APIUM,

APIUM petroselinum, parsley—common plain-leaved parsley—curled-leaved common parsley—broad-leaved, or large-rooted parsley; the two former for their leaves, and the latter for its root. All raised by seed in spring.

APIUM dulce, celery—common upright celery—upright celery, with solid stalks—turnep-rooted spreading celery—smallage, or wild, rank-tasted celery.

ASPARAGUS officinalis, common asparagus. By seed, and once raised the roots abide for years.

ATRIplex hortensis. Garden orach—white-leaved garden orach—green orach—purple orach. By seed annually.

BETA vulgaris. The beet, of which there are;

BETA cicla, common culinary beet—green-leaved culinary beet—white beet—chard, or great white Swiss beet. By seed annually.

BETA ruba, red beet—large, long, red-rooted beet—turnep-rooted red beet—red-rooted beet, with green leaves—pale-red beet; but those with dark-red leaves and roots are the only sorts for use. By seed annually.

BORAGO, borage. Some varieties. All raised by seed annually in autumn or spring.

BRASSICA, the cabbage, cauliflower, broccole, turnep, &c. The sorts are:

BRASSICA oleracea (Sylvestris) the cabbage, of which there are:—small early summer cabbage—dwarf early sugar-loaf-shaped cabbage—large, hollow, sugar-loaf cabbage—early Russia cabbage—common round white cabbage—long-sided hollow cabbage—oval hollow cabbage—flat-topped cabbage—musk-scented cabbage—giant cabbage—red cabbage. All by seed annually in spring and autumn, for use all the year.

BRASSICA sabanda, savoy cabbage—common green curled savoy—large green Dutch savoy—yellow savoy. By seed annually in spring, for autumn and winter use.

BRASSICA laciniata, lacinated, and other open-leaved cole—green curled borecole—red curled borecole—thick-leaved curled borecole—finely-fringed borecole—broad, erect, curled-leaved Siberian borecole, or Scotch cole, or kale, red and green—common plain-leaved green colewort; none of these ever cabbage, but always remain open and loose quite to the heart; are remarkably hardy, and proper for winter use; all raised by seed annually in spring and summer.

BRASSICA caulorapa, turnep-cabbage—turnep-cabbage, with the turnep above ground—with the turnep under ground. By seed.

BRASSICA cauliflora, the cauliflower—early cauliflower—late cauliflower. By seed annually in spring and autumn.

BRASSICA Italica, Italian brassica, or broccoli—early purple broccoli—late large purple broccoli, comprehending some varieties, with blue, brown, green, and yellowish heads—white, or cauliflower-broccoli—black broccoli. All by seed in spring and beginning of summer, for autumn, winter, and spring use.

BRASSICA rapa, the turnep—early Dutch turnep—white round turnep—green-topped turnep—red-topped turnep—yellow turnep—oblong white turnep—long white-rooted French turnep—round purple French turnep. By seed in spring and summer, for use most part of the year.

CALENDULA officinalis, common officinal marigold, several varieties. By seed annually in spring, summer, or autumn.

CICHORUM endivia, endive—green curled endive—white curled endive—broad-leaved Batavia endive. By seed annually in summer, from May till July, for autumn and winter service.

COCHLEARIA armoracia, horse-radish. By pieces of the roots in spring, for use most part of the year.

CRAMBE, sea-colewort. By seed in spring, but once raised the roots remain for years, sending up shoots for use in spring and summer.

CUCUMIS, the cucumber and melon. The sorts are:

CUCUMIS sativa, the cucumber—early short prickly cucumber—early cluster-cucumber—long, green, prickly cucumber—long, white, prickly cucumber—long, smooth, green, Turkey cucumber—large, smooth, white cucumber—large, smooth, green, Roman cucumber. All by seed annually in spring and summer.

CUCUMIS melo, the melon—Roman melon—Cantaleupe melon; of each some varieties, and several other sorts; see their *Culture*. By seed annually in spring.

CUCURBITA, the gourd and water melon, of each different sorts; see *CUCURBITA*. By seed annually in spring.

CYNARA, artichoke and cardoon. The sorts are:

CYNARA scolymus, common artichoke, of which are—globular-headed, red Dutch artichoke.

K I T

choke—oval-headed, green French artichoke. By suckers from the sides of the old plants in spring.

CYNARA *cardunculus*, the cardoon. By seed annually in spring.

DAUCUS *carota*, the carrot—orange-coloured carrot—red carrot—yellow carrot—white carrot. By seed annually in spring, summer, and autumn; for use most part of the year.

HELIANTHUS *tuberosus*, tuberous sunflower, or Jerusalem artichoke. By pieces of the root in spring.

HYSSOPUS *officinalis*, common officinal hyssop. By seed in spring, and by slips and cuttings of its branches.

LACTUCA, lettuce—early green cabbage-lettuce—white cabbage-lettuce—brown Dutch cabbage-lettuce—great admirable cabbage-lettuce—green and white ball-cabbage-lettuce—green coss-lettuce—white coss-lettuce—black coss-lettuce—spotted Aleppo coss-lettuce—brown Silesia lettuce—imperial lettuce—red capuchin lettuce—green capuchin lettuce—curled lettuce. All by seed annually in spring, summer, and autumn; for use most part of the year.

LAVANDULA, lavender. The sorts are:

LAVANDULA *spica*, spike-flowered common lavender—common narrow-leaved—broad-leaved—blue flowered—white-flowered—and dwarf-lavender. By slips in spring.

LAVANDULA *stœchas*, stœchas, or French lavender. By slips or cuttings, and by seed.

LEPIDIUM *fativum*, garden-cress—common small-leaved—broad leaved—curled-leaved. By seed at different times of the year, according as the plants are wanted.

MELISSA *officinalis*, baum. By dividing the roots in spring or autumn.

MENTHA, mint, penny-royal, &c.

MENTHA *viridis*, green common spear-mint—curled-leaved spear-mint—variegated spear-mint. By dividing the roots, by young plants, and by cuttings of the stalks in spring.

MENTHA *piperita*, pepper-mint. By roots and plants, &c. like the former.

MENTHA *pulegium*, penny-royal. By dividing and slipping the plants, as for themint.

OCYUM *basilicum*, basil. Several varieties, see OCYUM. By seed in spring.

ORIGANUM, marjoram—common, wild, perennial pot-marjoram—winter perennial sweet-marjoram—marjorana, or annual sweet-marjoram. By seeds in spring, and the two former also by slipping the roots.

K I T

PASTINACA *fativa*, parsnep. By seed annually in spring, for winter use.

PHASEOLUS *vulgaris*, common kidney-bean, which may be divided into two classes, —dwarfs and runners.

————— *Dwarfs*, are—early white—early yellow—liver-coloured—speckled dwarf—Canterbury white dwarfs—Battersea white dwarf—large white dwarf—cream-coloured dwarf—black dwarf—sparrow-egg dwarf—amber-speckled dwarf. All by seed annually at different times from April till August.

————— *Running kinds*—scarlet runner, and white variety—large Dutch runner—Battersea white runner—Negro runner—variable runner. By seed like the former.

PISUM, the pea—Charlton pea—golden Charlton—earliest golden Charlton—long Reading hotspur—Spanish morotto—green nonpareil—early dwarf marrowfat—large marrowfat—green rouncival, or union—white rouncival—Ledman's dwarf pea—small sugar-pea—large sugar-pea—cluster-pea—crown-pea—egg-pea—fickle-pea. All by seed annually, at different times from October till June.

PORTULACA *oleracea*, purslane—green purslane—golden purslane. Both by seed, in April and May.

POTERIUM, *sanguisorba*, burnet. By seed and parting the roots.

RAPHANUS *fativus*, the radish—short-topped early radish—long topped radish—deep-red radish—pale-red, transparent, mild radish—salmon-coloured radish—small white turnep-rooted radish—large, white, turnep-rooted, Spanish radish—large, black, turnep-rooted, Spanish radish. All the sorts by seed at different times from Christmas till July or August; but the latter for winter use.

ROSEMARINUS, rosemary, some varieties. By layers, slips, and cuttings, in spring.

RUMEX *acetosa*, sorrel—common long-leaved sorrel—round-leaved French sorrel—barren sorrel. By parting the roots, and the first sort also plentifully by seed.

RUTA *graveolens*, rue; several varieties. All by slips and cuttings.

SALVIA, sage, clary, &c. The sorts are:

SALVIA *officinalis*, common sage—red sage—broad-leaved green sage—narrow-leaved green sage—broad leaved hoary sage—sage of virtue—wormwood sage, &c. By slips in April and May.

SALVIA *selarea*, clary. By seed annually.

SATU-

SATUREJA, savory—winter perennial savory—summer annual savory. Both by seed, and the former also by slips.

SCANDEX *cerefolium*, chervil. By seed annually in August, for winter and spring use.

SCORZONERA, *scorzonera*, an eatable root, raised from seed in spring.

SINAPIS, mustard—white mustard—black mustard—field, or wild mustard: the former to use young in salad, and the two last for their seeds, to make mustard. All by seed in spring, or if for salads, at any time of the year.

SIMUM *fisarum*, skirret; an eatable root. By off-sets commonly, of the root, also by seed.

SOLANUM, night-shade, furnishes the potatoe and tomatoe. The sorts are:

SOLANUM *Tuberosum*, tuberous-rooted solanum, or potatoe—common round red potatoe—early round red—oblong red—deep red—pale red—rough red—white kidney-shaped—red-ended white kidney—white round—white cluster—prolific American. By pieces of the roots, or the roots whole, in spring.

SOLANUM *lycopersicum*, tomatoe, or love-apple; some varieties. All by seed annually.

SPINACIA, spinach—round thick-leaved, or smooth-seeded—triangular-leaved, or prickly-seeded; the former for spring and summer

crops, the latter to stand the winter. Both by seed annually in spring, summer and autumn, for use most part of the year.

TANACETUM *vulgare*, common tansey. By parting the roots in spring or autumn.

THYMUS *vulgaris*, common thyme; having some varieties. By seeds in March and April; also by slips of the root and branches, and by cuttings; but seed is the only way to raise a quantity of the common sort; and the other methods to continue the varieties.

TRAGOPOGON *porrifolium*, falfafy; an esculent root. By seeds annually in spring.

TROPÆOLIUM, Indian cress, or nasturtium—nasturtium minus—nasturtium majus; their flowers for garnish and salads, and their seeds to pickle. Raised annually from seeds in spring.

VALERIANA *lacusta*, corn-salad, or lambs-lettuce. By seed in spring and autumn.

VICIA *faba*, the bean—early Mazagan—early Lisbon—long-pod—Turkey long-pod token bean—Sandwich bean—Windfor bean—white-blossomed—red-blossomed—Spanish bean—nonpareil bean—dwarf fan bean, very low. All of them by seed annually, at different times from October until June.

For a particular description, and method of culture of all these Kitchen garden plants, see each under its respective genus as above.

L.

LABIATUS *Flos*, a lip-flower; a monopetalous irregular flower, divided into two principal divisions, resembling two lips.

Labiated, or Lip-flowers, make part of the ringent, or grinning tribe; see **COROLLA RINGENS**; and of which are most of the verticillate plants, as baum, mint, hyssop, sage, clary, marjoram, savory, lavender, thyme, and many others, most of which produce their flowers in a verticillus, or whirls round

the stalks and branches. See **VERTICILLUS**.

LABYRINTH, a sort of wilderness-plantation, abounding with hedges and walks, distributed into many winding and intricate turnings, leading to one common centre, extremely difficult to find out; designed in large gardens by way of amusement.

A Labyrinth is formed with hedges commonly in double rows, leading in various intricate turnings, backward and forward, with

with intervening plantations and gravel walks alternately between hedge and hedge; and the great aim is to have the walk contrived in so many mazy, intricate windings to and fro, that a person may have much labour and difficulty to find out the centre of the Labyrinth, by meeting with as many stops and disappointments as possible; for he must not cross or break through the hedges; so that in a well-contrived Labyrinth a stranger will often entirely lose himself, so as neither to find his way to the centre, nor out again the way he came in.

These Labyrinths are rarely introduced now in our modern garden designs; and scarce to be seen, but in some old noble gardens.

As to the plan of them, it is impossible to express it with any propriety by words, no farther than the above hints; but there are different plans, and the contrivance of them must depend on the ingenuity of the designer.

But as to their hedges, walks, and trees; the hedges are usually of hornbeam, but may also be of beech and elm, or any other that can be kept neat by clipping, see HEDGES. The walks should be five feet wide at least, laid with gravel and neatly rolled; and the trees and shrubs to form a thicket of wood between the hedges may be any of the hardy kinds of the deciduous tribe interspersed, if you please, with some ever-greens; and in the middle of the Labyrinth should be a spacious open for the centre.

Sometimes small Labyrinths are formed with box-edgings, and borders for plants, and alleys for walking, in imitation of the large ones, and which have a good effect in small gardens.

LACTESCENTIA, milkiness; Lactescent plants, are such as abound with a milky juice, such as lettuce (*lactuca*), dandelion, and many others.

The colour of the juice in question, is white in most plants, though in some it is yellow, in others red; most Lactescent plants are said to be poisonous, except those with compound flowers, which are of an innocent quality.

Among the poisonous sorts may be reckoned, *euphorbia*, fumach, celandine, cassida, cardinal-flower, swallow-wort, apocynum, &c.

Among those innocent in their quality, are all the sorts of the *lactuca sativa*, or cultivated lettuce, falfafy, dandelion, &c.

LACTUCA, Lettuce.

One species only of this genus furnishes all our valuable varieties of Lettuce; all of which are herbaceous annuals of great estimation for fallads, and many culinary purposes; are in greatest perfection in summer, but may be continued most part of the year; though being rather impatient of severe frost, cannot be obtained in any tolerable perfection in winter, unless planted under shelter of frames, &c. their cabbaged inner leaves are the useful parts, which having obtained perfection, the plants soon after shoot up tall branchy stalks, terminated by compound yellowish flowers.

Class and order, *Syngenesia Polygamia Æqualis*.

Characters.] CALIX, a compound flower, having a scaly imbricated general cup. COROLLA, many tongue-shaped hermaphrodite flowers, placed imbricatum. STAMINA, five short filaments, and cylindric antheræ. PISTILLUM, an oval germen, slender style, and two reflexed stigmas. PERICARPIUM, none. SEMINA, a single compressed seed to each floret, crowned with a simple down, sitting on the receptacle.

The cultivated species of Lettuce is;

LACTUCA *Sativa*.

Cultivated Lactuca, or Common Lettuce.] Hath a long taper root, crowned by many large roundish, or oblong oval, close-sitting leaves, in some spreading, others erect, the inner ones contracting gradually, and form a close, firm, cabbaged head; and from the centre of which rises the flower-stalk, branching two or three feet high, having all the branches terminated by small compound yellow flowers, succeeded by small, flat, downy seeds, in autumn.

The varieties of this species are very numerous, but the real valuable sorts now commonly cultivated, do not amount to above six or seven; and it is better to cultivate only a few of the known good kinds, than to confuse the ground with a great multiplicity of sorts, unless required merely for variety. We will, however, exhibit a list of the principal, and less material varieties separate.

Principal Varieties.] Hardy green cabbage-lettuce—white cabbage-lettuce—great, admirable, white cabbage-lettuce, very large—brown Dutch cabbage-lettuce—green coss-lettuce—white coss-lettuce—brown Silesia-lettuce. All the cabbage kinds are of spreading

ing growth, but cabbage firmly; and the other sorts grow upright, and also cabbage very large.

All these seven varieties are excellent Lettuces for general culture, though the green, and the white cofs kinds, are in most esteem for the general summer crops; and the green cofs rather excels all the cofs kinds for size and goodness; but as all the above varieties both of the cabbage and cofs kinds cabbage exceeding fine, a few of each is worth culture in every garden for general use; but rather most of the cofs kinds for summer, and most of the others for autumn and winter; and the hardy cabbage, brown Dutch, and green cofs, are proper also to stand the winter for spring service; but if thought proper some of each sort may be used for either or all of these seasons, except the great admirable Cabbage-lettuce, which being rather tender, at least, does not succeed for early nor late crops, so should be sowed principally in April and May, and will cabbage remarkably fine in July and August. All the other varieties, however, may be sowed any time in spring, summer, and autumn. See their *Propagation*, &c.

Less material Varieties.] Small, early, green ball-cabbage Lettuce—white ball-cabbage Lettuce: both these are varieties of the common green and white Cabbage-lettuce—green capuchin Lettuce—red capuchin Lettuce—imperial Lettuce, large—spotted Cofs-lettuce—black Cofs-lettuce, large and somewhat spreading. All these varieties cabbage to firm heads; though inferior to the former class of varieties for general use; but their culture is all the same as the others; and, if required for variety, may be raised abundantly by seed in spring, summer, and autumn. See their *Propagation*.

All the above varieties of Lettuce in each class, are tolerable permanent, especially if care is taken to save seeds only of the very best of each sort; and the different sorts always as far distant from each other as possible, that their *farina* may not mix and cause a degeneracy, for it is by not strictly observing this that so many are disappointed in their crops, by having Lettuce not of the approved sorts, and those often small and insignificant, running to seed before they have half cabbaged; therefore great regard should be had in the choice of the plants for seed, according to the above hints, and as directed under the article of *saving the seed*, by which you

may depend on continuing plants of the approved kinds in the utmost perfection.

The plants in general may be considered both as annuals and biennials, for those sowed in spring and summer, attain perfection, run up to seed, and perish the same year; but the autumn sowings will stand all winter until spring following, when they attain perfection, then shoot up for seed, and perish root and all.

All the sorts are hardy enough to grow in any common soil of a kitchen-garden, in a free situation open to the sun and air; but being rather impatient of severe frost and wet soils in winter, should have a dry warm situation in that season, and some should be kept under frames and other shelters, the more effectually to preserve, and forward them for use during that season and spring-time.

Their use is principally for fallads, when arrived to full growth and cabbaged, that the inner leaves become blanched, crisp, and sweet, otherwise would eat tough and bitter tasted; but sometimes also the young open plants of the cabbage Lettuces are used in spring, till the other general crops arrive to perfection: the white cabbage being the most eligible for this use, as they eat sweeter than any other sorts while young and open. Quite young open Lettuces are also often used as small fallad herbs, sowing them thick in rows, like cressies, &c. and gather them for use in the same manner as for those plants; but this mode of culture is more particularly practised in winter and spring. Lettuces, however, in general eat no way so crisp, sweet, and palatable, as when fully cabbaged; and are themselves sufficient for a fallad, if thought proper, without the addition of other herbs. The fully cabbaged Lettuces are also excellent for stewing and for soups, and other culinary uses.

The season of Lettuces may be continued most part of the year, by different sowings; but their principal season of greatest perfection is June, July, and August, in which months the spring-sowed plants arrive to a large size, and finely cabbaged. However, by several different sowings in spring, summer, and autumn, they may be had cabbaged less or more the year round: the spring sowings furnish the main summer crops, the summer sowing for autumn use; and the late autumnal sowing, stand the winter, and some of which will be fit for use in that season, and if occasionally sheltered, some will be tolerably

tolerably cabbaged; and others arrive to perfection in spring and beginning of summer, before the spring-sowed plants come in.

Propagation, and Season for sowing all the Sorts.

The propagation of all the sorts of Lettuce is by seed annually, and that to continue a regular succession of them for use at all times of the year, six or eight different sowings, at least, is necessary; but the principal sowing-season for the main crops, is spring, in February, March, April, and May; which will furnish a constant supply of good Lettuces from May till August or September; and by latter-sowings they are continued longer accordingly: as the plants, however, of all the sowings, after having attained their proper size, and fully cabbaged, they soon after run up to seed, so that to insure a continued succession as long as possible, a sowing may be performed every three weeks or month, from January until September or October. The spring and summer-sowings furnish Lettuce for use from April or May until November; and the autumn-sowings in August, September, and October, come in for use late in autumn, and in winter; and for early spring Lettuces, as before observed, in warm borders, under walls, and in frames, and other shelter; observing that all the sorts succeed either by remaining where sowed, thinning them to proper distances; or by transplantation, placing them a foot at least asunder; but it is proper always to transplant a principal quantity of each sowing, both to thin the standing plants properly, and to obtain a longer succession of each crop, for the transplanted Lettuces will succeed the standing plants for use, and often grow larger, and generally remain longer in perfection before they run.

The main crops of Lettuces should generally be sowed distinct from other crops, and each different variety separate; they, however, are very commonly sowed thin among other small crops, to save ground; some of the plants designed for transplantation into other places, and some to remain at good distances for cabbaging; so are frequently sowed among early radishes and spinach, also among onions, leeks, carrots, parsneps, &c. particularly the upright sorts of Coss-lettuces; any of the sorts are likewise often sowed thin among winter spinach, but chiefly the common green cabbage, and brown Dutch kinds;

but in sowing any sorts of Lettuces among any of these crops, a thin sprinkling should only be admitted; but when there is plenty of ground, I should be for sowing the main crops principally distinct by themselves, and the plants thinned out, leaving some to remain for cabbaging where sowed, and transplant the rest into another spot of ground as hereafter directed.

Observe, as before noticed, that when intended to have early young open Lettuces for spring use, the white cabbage kinds are the proper sorts to sow for that purpose, and may begin to thin the young plants for use, when their leaves are an inch or two broad, which may be continued as they are wanted, leaving some at regular distances to arrive at full growth.

But for full-grown Lettuces, it is proper to sow the different sorts both of the principal cabbage and coss kinds at the same time in separate spots of ground, whereby you will have a regular supply of each sort, only observing at each sowing to sow most of those sorts that are in the greatest request either for family use or market; remarking the sorts, as before directed, that are the most proper for use at the different seasons of the year, and the different times of sowing as above mentioned.

The early sowings of all the sorts should be performed on a warm border, or some dry sheltered situation, to have the crops as forward as possible; and if required to have a few early Lettuces as forward as can be, they may be greatly forwarded by sowing in a slender hot-bed in January or February; particularly the white and green Coss-lettuce, and if the young plants of an inch or two high are pricked out into another slight hot-bed, it will still bring them more forward; and after having a month's growth some may be thinned out in mild weather, and planted a foot distance in the open ground; but in default of hot-beds, a few may be sowed in frames, or under hand-glasses in a bed or border of natural earth, to have shelter on nights and cold weather, which may bring them a little forwarder than those fully exposed. The sowing, however, in a hot-bed, or under frames, &c. is more particularly necessary after a severe winter, when the autumn-sowed crops of Lettuces designed for spring use are cut off; but in mild winters, when a plentiful supply of the autumn Lettuces have survived the winter, there will be little

little occasion for any other precaution than to sow the earliest spring-sowings on warm borders, &c. as aforesaid.

But the general spring and summer-sowings for the main crops, for summer and autumn use, should be performed principally in any open situation, in the quarters, or large open borders, the more distant from spreading trees and bushes the better; the same should also be observed in the transplanted Lettuces, for when under, or too near shady places, they always draw up weak, never cabbage large, and soon fly up to seed; whereas those in a free exposure are of robust growth, and cabbage large and firm.

The sowings of all the sorts at every season is performed principally by broad-cast on the surface; observing, as the seeds are small and thin, particular care is requisite in sowing, to spread them regular, and not too thick, and rake them in with an even hand; or those sowed in hot-beds under frames, may, instead of raking-in, have earth sifted over them near a quarter of an inch deep; and in about from eight or ten to fifteen or twenty days after sowing, in either method, the plants will appear, which are to be managed according to the following directions.

Their general Culture.

When the plants of each sowing come up, their principal culture is to keep them clean from weeds, thin them where too close, and transplant some of each sowing; but as to the earliest sowed plants, which come up early in spring, if attacked while very young with severe frost, those in borders may be defended with a light covering of dry long litter occasionally; and those in hot-beds, or under frames, &c. in the full ground, by covering with the glasses. The weeding and thinning the different crops of these plants may be performed either by hand or hoe; observing, if designed to have the principal crops of plants to remain where sowed to attain perfection, and that they form a crop of themselves, hoeing will be the most beneficial, both to destroy weeds and thin the plants to proper distances, leaving them fifteen or eighteen inches asunder, unless it is necessary to thin them by degrees, either by occasional transplantings, or by drawing out young plants for use, as they may be wanted; but when any considerable quantity of the plants are designed for transplantation,

which is adviseable in every crop, the weeding and thinning should principally be performed by hand; so thinning out the largest plants occasionally for transplanting, leaving enough of the others at regular distances, as above, for a crop to arrive to full size. It is, however, always proper to transplant some of each sowing, by which you will have the longer succession of good plants.

When designed to transplant any sort of Lettuce, it should be done when the plants are about three or four inches high, not more, for when larger they are apt to flag greatly, and do not root so freely as younger plants: moist weather will be particularly necessary for this work. Take up the plants with care, so as to preserve as much root as possible; and proceed to plant them by line and dibble, in rows, a foot at least asunder, but if fifteen or eighteen inches distant the better, especially for the larger kinds, such as the grand admirable cabbage Lettuce, and the white and green cofs, allowing the same distance between the plants in each row; and if set in the quincunx order, the plants will have still more room to grow. As soon as planted, give water, which should be repeated, if dry weather, several times for the first week or ten days, till the plants have taken fresh root, and beginning to advance in growth.

Thus continue planting out a quantity every three weeks, from March, April, or May, until September or October, whereby you will have a daily supply of good well-cabbaged Lettuces eight or nine months in the year; and those planted out late, will stand the winter, and cabbage early in spring.

If the summer transplantings are planted in shallow drills, it will be some advantage in facilitating the fresh-rooting of the plants, as the drills will confine the water given principally about the plants, and also retain the moisture longer than the level surface. See DRILLS.

Tying up Lettuces to forward their cabbaging, and to whiten and render them crisp, is often practised to the early spring and summer crops, particularly cofs Lettuces. When the plants are well advanced in growth, and beginning naturally to form their inner leaves for cabbaging, tie all their leaves up close together with a piece of bafs, a little above the middle of the plant, not too strait, but

but so as the whole plant may have room to grow; besides, if tied too close, they are apt to rot in the heart: this work of tying, however, is only necessary for some of the earliest plants of the forward crops, the succeeding ones will cabbage fast enough without that aid; only observing, if any sorts should be backward in cabbaging, as is often the case with the black cobs Lettuce, they may always be facilitated therein by the above practice.

Winter and early Spring Crops.

Winter Lettuces, both for winter use, and to stand the winter in warm borders and in frames, &c. for spring service, are obtained by two or three different sowings in autumn, from the middle or latter end of August until the end of September or October.

That is, to have Lettuces stand for use all winter, and early in spring, sow some hardy green and white cabbage Lettuce, brown Dutch, and green cobs, about the middle of August, and beginning of September, in any open situation, and the plants will come up in a week or ten days; about the end of September, and in October, plant out a parcel of the best plants of each sowing, in a warm dry situation, six or eight inches asunder; and at each planting, plant also some under frames at the same distance; to be covered with glasses every cold night, and all bad weather; or for want of frames, plant them under hand-glasses, or in a bed arched over with hoops or rods, to be covered with mats in winter frosts; but if you use frames, chuse them as shallow as possible, and sink the back part in the ground, so as to be only equal in height with the front, that the surface of the bed and plants may be all an equal distance from the glasses, if not more, at first, than six or eight inches, the better, as it will prevent their drawing up weak and open, which is the case when in very deep frames, but in shallow ones, they will be more robust and close, and being nearer the glasses, they will be forwarded more in growth during winter. Under either of the above shelters, let the plants enjoy the free air in mild dry weather; but cover them every cold night, with the proper covers, especially after October, also in all very cold, and in very wet weather, day or night, particularly those in frames and under glasses; and as to those in hand-glasses, they may have the glasses almost constantly over them in winter, tilting up one side in mild weather,

and only set them entirely off in fine mild dry days; but in sharp frosty weather keep those under every kind of shelter quite close; allowing also additional covering of mats or litter, when the frost is very intense; those in the borders may also be defended by some light litter; but at no time suffer the covering to remain longer on any of the crops than the bad weather continues, but indulge them with free air every mild day. By the above practice you may have Lettuces for use most part of winter, and early spring, particularly the cabbage Lettuces: those planted out first will be fit for use in November and December, and the second planting will come in towards Christmas, and being sheltered by the glasses, will continue coming in for winter and spring use till succeeded by the other latter autumn sowings; observing according as any are gathered out of the frames or glasses, some may be removed from the borders to fill up the vacancy, whereby the glasses may be constantly employed during the winter.

Sometimes for Lettuces intended to be planted in frames late in autumn for winter use, a moderate hot-bed is made for their reception, in order that they may be well forwarded in the beginning of winter, and if the heat is continued moderately by aid of linings, allowing plenty of air all mild weather, the plants will be very fine by Christmas, or thereabout.

Winter-standing Spring Crops.

But to have Lettuces principally for spring use, some seed should be sowed towards the middle and latter end of August to stand the winter, some where sowed, others to be transplanted into warm borders, to stand without any other shelter than that of the walls or other fences; and another sowing should be performed about the middle of September, to raise plants for pricking under frames to have shelter of the glasses all winter, to be as a reserve in case those in the borders are destroyed; if both stand, one will succeed the other.

In the former case, a quantity of the plants, when two or three inches high, in October, or early in November, should be planted out into a warm dry situation, in rows south and north, six inches asunder, and here let them remain to take their chance all winter: out of the whole many of them will probably escape the frost; but in very severe weather they

they may be protected by a light covering of dry long litter, which remove away again in due time when the frost breaks. In March or April, if they remain too thick, some should be thinned out and planted in another place, in rows, twelve or fifteen inches asunder; these crops, thus wintered in the open ground, will come in for use in April and May, to succeed those others sowed in autumn, and sheltered occasionally all winter, and will remain good till the spring sown plants come in.

In the latter case, i. e. those sowed in September, to be wintered in frames, should be planted therein about the latter end of October, or beginning of November, planting them in rows from the back to the front of the frame, three inches distance; close the earth well about each plant, finish with a moderate watering all over the plants, and put on the glasses to promote their more speedy rooting anew, shoving the lights, however, two or three inches down, to give vent to the moist vapour arising from the mould; but when the plants have taken fresh root, and set to growing, admit the full air every mild dry day, by taking the glasses entirely off, which must be continued throughout the winter season, in all dry mild weather, but put them on every night, in cold or very wet weather especially; even also adays when great rains prevail; and in frosty weather keep the glasses always on, except in the middle of sunny days, but when the frost is very severe, keep them close night and day, using also other covering of mats or long litter over the glasses, and around the sides of the frame. During the winter, keep all decayed leaves picked off; and as the spring and warm weather advances, let them have the benefit of warm showers.

Those thus wintered may be effectually preserved, if those in the open ground should be destroyed by the frost or excessive moisture.

In March transplant some of them into the open ground, in rows, a foot at least asunder, water them moderately till fresh-rooted; observing to leave a crop remaining in the frames or winter-bed, a foot also apart, to stand to cabbage; which will arrive to perfection some considerable time before the transplanted ones, and those that have been fully exposed all winter.

For want of frames for the above purpose, a quantity of the plants may be pricked out under hand or bell-glasses in autumn, to stand

the winter, either by themselves for a full crop, or may plant some under the hand or bell-glasses, that are placed over early cauliflowers, as practised by the London gardeners, planting them round just within the glasses; managing them as directed for the frames; and early cauliflowers under hand or bell-glasses; or for want either of a sufficiency of frames or hand-glasses, plant out a quantity in autumn, in four-feet wide beds, in a warm situation, and arch them over with hoops or rods, to cover with mats and litter in bad weather, as aforesaid: they will here have a better chance of surviving the winter than those fully exposed; and in spring transplant a quantity, by way of thinning, into other beds, as as above directed.

Lettuces are sold in the markets by the score, which in London, those that come in early, often fetch from half a crown to five shillings, but fall gradually in price, as the season advances, to six pence or three pence per score, two and twenty to each score; though the fine large cois Lettuce seldom much less than a shilling per score of plants.

Saving Seed of all the Sorts.

To save Lettuce seed. Let it be remarked, that some of the early plants of all the sorts should principally be chosen for seed plants, for those of the latter crops rarely run soon enough to ripen seeds perfectly before they are attacked by the autumnal rains and cold, which greatly retards the ripening of all sorts of Lettuce seed; therefore, select either some of the the winter-standing plants, or some of the forwardest plants of the February or March sowing; and the largest and best cabbaged of each respective kind, mark this, if you would continue your Lettuce fine; likewise it is of importance, as before hinted, to have the different varieties intended for seed, at some distance from each other, because, if too near, the *semen masculinum* of the different sorts may mix and fecundate one another, and thereby a degeneracy or mongrel breed will be the consequence, and the true sorts would in time be lost; and it is by not observing the above particulars by those who save large quantities of seed for sale, that so many bastard bad sorts of Lettuces are dispersed about the country.

The seed ripens in August and September, but that of each plant rarely ripen all equally together, so that according as it arrives

rives to perfection, the respective branches should be cut off in dry days, and spread upon a cloth, or tied in small bunches, and hung up across lines in a dry airy loft, for a week or two to dry and harden; then beat them out, and clean them from the down and other rubbish, and expose them upon cloths a few days to dry for keeping; then put them up in bags for use, and hang them in a dry room.

In many places where the farming gardeners cultivate great quantities of these plants in fields for seed, to serve the dealers, they pay but little regard to the goodness of the plants, but when they are a few inches high, hoe them out to about a foot distance, leaving them good, bad, and indifferent to stand to seed, which is very wrong, as many persons are thereby disappointed of their crops, by having most of the plants run before they are half-grown: the cultivators for seed should, therefore, after the first hoeing, look over the plants from time to time, and clear out all those that run up for seed before they cabbage, and reserve only those that are largest and best cabbaged.

All sorts of Lettuce produce the greatest quantities of seed in dry warm seasons, and in wet cold autumns they ripen seed very sparingly, and that late, and often very indifferent in respect to goodness for sowing.

Lettuce seed is sold in the shops by retail, at from six pence to a shilling the ounce; and may be had in any quantity from a quarter of an ounce to a pound, as shall be convenient, according to the extent of the garden, or demands of a family for the plants.

LANTANA, American Viburnum.

This genus consists principally of shrubby exotics of Africa and America, for the greenhouse and stove; growing a yard or two high, adorned with oval, oblong, and roundish simple leaves, and monopetalous tubular four-parted flowers.

Class and order, *Didynamia Angiospermia*.

Characters.] CALIX, is monophyllous, short, tubular, and four-parted. COROLLA, is monopetalous, with a cylindric tube, spreading at top, and divided into four obtuse segments. STAMINA, two long and two short filaments, and roundish antheræ. PISTILLUM, a roundish germen, slender style, and crooked stigma. PERICARPIUM, a roundish drupaceous unilocular fruit, containing a roundish bilocular nut.

There are about four or five species retained in the English gardens, two for the greenhouse, the others for the stove.

Green-house Kinds.

¹LANTANA *Africana*.

African Ilex-leaved Lantana.] Hath a shrubby stalk, branching irregularly five or six feet high; oval, pointed, serrated, close-sitting, alternate leaves, and white flowers, singly from the sides of the branches.

²LANTANA *Salvifolia*.

Sage-leaved Lantana.] Hath a shrubby stalk, branching five or six feet high; oblong, pointed, rough, close sitting, opposite leaves, four or five inches long; and flowers in clusters from the upper parts of the branches.

Hot-house Kinds.

³LANTANA *Trifolia*.

Trifoliate Lantana.] Hath a shrubby, woolly-barked stalk, branching about a yard high; oblong, indented, rough leaves, placed some by threes, others opposite; and purple flowers in oblong roundish spikes from the ends of the branches.

⁴LANTANA *involucrata*.

Involucrum-headed Lantana.] Hath a shrubby stalk, branching four or five feet high; roundish, indented, rough leaves, by pairs opposite; and from the ends of the branches, umbellate heads of purple flowers, attended by many small leaves like an involucre.

⁵LANTANA, *Camara*.

Camara, or Leafless-headed Lantana.] Hath a shrubby stalk branching five, six, or eight feet high, in different varieties; oblong, indented, rough opposite leaves, two or three inches long; and from the sides and ends of the branches umbellate heads of yellow, purple, or red flowers in the varieties, unattended by leaves.

Variety.] Nettle-leaved leafless-headed Lantana.

⁶LANTANA, *Aculeata*.

Prickly Lantana.] Hath a shrubby stalk, branching three or four feet high, the branches angulated and armed with crooked spines; oval, spear-shaped, hairy, opposite leaves; and from the sides and ends of the branches umbellated heads of scarlet flowers, having the centre ones yellow or orange-coloured.

All these species have durable woody stalks and branches, retaining their leaves mostly all the

the year, most of which are very rough; the flowers of all the sorts are of one petal with a cylindric tube, divided above into four parts, (see the *Characters*) and appear from June or July until winter; sometimes succeeded by largish berry-like fruit, ripening here in warm autumns.

These plants are all of foreign growth; the two first of Africa, and the others of the warm parts of America; and all of them require shelter here in cold weather, the two former of the green-house, and the other four of the stove; so must be always kept in pots of light rich earth, and placed among the plants of those two departments; the two green-house kinds may be placed in the open air all the summer; but the others only in the hottest months of that season.

Their propagation is by seeds and cuttings, in hot-beds.

By Seed.—Sow it in pots of light earth, and plunge them in a bark hot-bed, and when the young plants are some inches high, prick them in separate small pots, and plunged also in the bark-bed; and inure the green-house kinds to the open air in summer, the others but little the first season.

By Cuttings.—Cuttings of the young branches may be p'anted in pots in spring and summer, and plunged in a hot-bed, they will readily take root, and shoot at top the same year.

LATHYRUS, Chickling Vetch, comprising the everlasting and sweet-pea, &c.

The plants are herbaceous climbers; of which there are three noted species of the flowery tribe, proper for the decoration of the pleasure-garden; a perennial, and two annuals; all of them rising with cirrhous climbing stalks, mounting upon support several feet high, adorned with diphyllous cirrhous leaves, and papilionaceous flowers.

Class and order, *Diadelphia Decandria*.

Characters.] **CALIX**, is monophyllous, bell shaped, and five-parted at top. **COROLLA**, is papilionaceous, having a heart-shaped standard, two oblong, lunulated blunt wings, and a half-round keel. **STAMINA**, ten diadelphous filaments, and roundish antheræ. **PISTILLUM**, an oblong narrow compressed germen, flat acuminate style, and hairy stigma. **PERICARPIUM**, a long compressed, acuminate, bivalvular pod, filled with roundish seeds, like garden-peas.

There are many species of this genus, but not more than three that are commonly cultivated; all of which are for ornament.

¹**LATHYRUS** *Latifolius*.

Broad-leaved perennial Lathyrus, commonly called Everlasting Pea.] Hath thick, fibrey, perennial roots; climbing, thick, branching, annual stalks, having membranaceous wings between the joints, rising upon support by their cirrhi six or eight feet high; diphyllous leaves, of two spear-shaped lobes, terminated by clasps; and numerous large red or purple flowers, on long foot-stalks, appearing plentifully from June till October, succeeded by abundance of seed.

²**LATHYRUS** *Odorata*.

Odoriferous annual Lathyrus, commonly called Sweet-scented Pea.] Hath a fibrey annual root; a climbing stalk, rising upon support, by its clasps, three or four feet high; diphyllous leaves, of two oval lobes, terminated by climbing tendrils; and flowers by twos on long flower-stalks; of different colours in the varieties.

Varieties of this are] Purple-flowered sweet-pea—white-flowered sweet pea—variegated, or painted-lady sweet-scented-pea. All of which flower in summer, from May or June until October, by different sowings.

³**LATHYRUS** *Tangitanus*.

Tangier annual Lathyrus, commonly called Tangier Pea.] Hath a fibrey annual root; climbing stalk, rising upon support four or five feet high; diphyllous leaves, of two spear-shaped alternate lobes, terminated by tendrils; and from the joints of the stalk, large reddish flowers by twos, on long foot-stalks.

All these species of *Lathyrus* are herbaceous, and of hardy growth, their stalks long, slender, and furnished with cirrhi, or clasps for the purpose of climbing and supporting themselves; the first sort, *Lathyrus Latifolius*, is perennial, or everlasting in root, but annual in stalk; and the other two are annual in stalk and root, rising from seed in spring, and wholly perish in autumn. They all merit culture as flowery plants, but the perennial sort is the most valuable, both for its durability in root, and long continuance in bloom; the two annual sorts, however, flower very ornamentally, and by three or four different sowings, may be made to flower all summer and autumn.

The flowers of all the species are papilionaceous, or butterfly-shaped, having four irregular petals, i. e. a vexillum, or standard, two side wings, and a keel at bottom, succeeded by a long compressed pod filled with pea-like seeds.

The

The plants are proper ornamental furniture for any of the compartments of the pleasure-garden, as they prosper in any common soil; but they must be allowed support to climb upon, for they will climb by their clasps, or cirrhi, on any neighbouring support, such as sticks, bushes, trees, or any thing they can lay hold of; so should be sowed in patches about the borders, and branchy sticks, such as is used for sticking peas, placed for them to ascend upon, and they will flower beautifully all summer and autumn. The everlasting pea is also proper to be placed to run up the sides of arbours and trees, and against walls and other fences, where it will have a very fine effect.

Propagation, &c.

Propagation of all the sorts is by seed in the common ground in patches, where it is designed the plants should flower, for they do not succeed so well by transplantation.

They should be sowed principally in spring, though if sowed in autumn, the plants will flower earlier the following year, and the perennial sort once sowed, the same plants remain for years by the root, and produce new stalks annually; but the annual species must be sowed annually, and that in order to continue a succession of bloom from the earliest part of summer, until the end of autumn, three or four different sowings is necessary; the first sowing may be in autumn in November or December, or very early in spring; a second in March or April; and a third in May, &c. by which you will have plants producing flowers in constant succession three or four months.

Sow each species and variety in separate patches, five or six seeds in each, about an inch deep; when the plants are come up a few inches high, place some neat branchy sticks of proper height to each patch of plants for them to climb upon, and keep them clean from weeds, which is all the culture they require.

The first may also be propagated by transplanting some of the roots in autumn, winter, and spring; but those rarely succeed so well as sowing the seeds where the plants are to remain.

LAVANDULA, Lavender.

The plants are principally under-shrubby ever-greens, proper both for oeconomical uses of a family, and for the shrubbery and

green-house, growing two or three feet high very branchy and bushy, closely ornamented with small leaves; in some entire, others divided; and numerous small monopetalous labiated flowers in erect spikes.

Class and order, *Didynamia Gymnospermia*.

Characters.] CALIX, is monophyllous and slightly indented. COROLLA, is monopetalous, tubulous below, ringent, and spreading above, the upper lip bifid; the under one equally trifid. STAMINA, two large and two short filaments, and small antheræ. PISTILLUM, a four-parted germen, slender style, and obtuse stigma. PERICARPIUM, none, four seeds lodging in the calix.

There are three species cultivated in the English gardens; two for the open ground, and one for the green-house.

¹LAVANDULA *Spica*.

Spikeflowered common Lavender, or Lavender Spike.] Hath a short shrubby stalk, closely branching from the bottom two or three feet high; small spear-shaped entire leaves; and from the ends of the branches, numerous, long, erect, naked spikes of small ringent flowers, of different colours in the varieties.

Varieties.] Common narrow-leaved Lavender, with blue flowers, and with white flowers—broad-leaved Lavender—dwarf Lavender: all of them flowering in July.

This species is the common Lavender, but the narrow leaved variety, with blue flowers, is the sort commonly cultivated for its flowers for medicine, &c.

²LAVANDULA *Stæchas*.

Common Stæchas, or French Lavender.] Hath a shrubby very branchy stalk, rising two or three feet high; very narrow spear-shaped, pointed, hoary leaves, opposite; and all the branches terminated by short bushy spikes of purple flowers in June and July; succeed by seeds in August.

Variety.] With white flowers.

³LAVANDULA *Dentata*.

Dentate-leaved Stæchas.] Hath a woody stalk, branching on every side three or four feet high; leaves deeply indented in a pinnated manner; and the branches terminated by scaly four-cornered spikes of flowers, appearing most part of summer.

All these plants are shrubby, durable in root, stem, and branches, and will endure several

several years in a moderately dry soil; but in a very moist soil are apt to go off in winter.

The two first species are proper both for the kitchen-garden, for medical and other family uses; and to plant in the pleasure-ground to adorn the front of small shrubby compartments, where they will encrease the variety very agreeably; and are finely-scented aromatics, both when growing, and their flowers when gathered, especially those of the first species, which are in great esteem for putting among cloaths, and distilling and other oeconomical uses.

The flowers of the first sort, are gathered for use in July, which being the time of their perfection, cutting off the spikes close in a dry day, and tie them in small bunches for use.

The above two sorts should generally be planted in a warm dry soil, in which they will be of the longest duration.

The third sort being tender requires shelter in winter, so must be potted and placed in the green-house collection, where it will effect a good variety.

Propagation, &c.

All the sorts are propagated plentifully by slips or cuttings of their young shoots in spring.

In March or April, take off a quantity of slips or cuttings, from three or four to six inches long, strip off the under-leaves, then plant them in a shady border, four inches asunder, give a good watering, repeat it occasionally in dry weather, and the plants will be well rooted in summer, each become a good plant fit to be transplanted into any place early in autumn, that is September or October; removing them, if possible, with balls of earth, and if intended to plant them for use, set them in rows two or three feet asunder, and two feet distance in each row; if any are designed for the shrubbery, they should be stationed singly at good distances near the front.

Those of the third sort should be potted to move to shelter in winter.

The *Lavendula Stoechas* is also often raised from seed. Sow them in March or April, in a bed of light earth, and rake them in evenly with a light hand; the plants will rise in about a month; if dry weather, give water, and when they are three inches high, prick them out in beds, half a foot apart, and wa-

ter them as they shall require until fresh-rooted; let them stand here till next spring; then you may thin out the best, and plant them where they are to remain.

LAVATERA, *Lavatera*.

This genus comprises some tall herbaceous flowery annuals, and shrubby perennials, for the pleasure-garden; all of them growing erect, from two or three to eight or ten feet high, garnished with large roundish heart-shaped, and angular leaves, and large quinquepetalous flowers, of the mallow kind.

Class and order, *Monadelphia Polyan-dria*.

Characters.] CALIX, is double and permanent, the exterior part is of one semitri-fid leaf, and the interior is quinquefid. COROLLA, five obcordate, plane, spreading petals. STAMINA, numerous monadelphous filaments, and kidney-shaped antheræ. PISTILLUM, an orbicular germen, short style and many bristley stigmas. PERICARPIUM, numerous small capsules collected into a head covered with a hollow shield, each capsule having a kidney-shaped seed.

The most noted species are the following annuals and perennials.

Annual Kinds.

¹LAVATERA *Cretica*.

Cretan Annual Lavatera.] Rises with an upright, branching, herbaceous stalk, two or three feet high, the lower branches very diffuse or spreading; large, roundish, lobated leaves, the upper ones acutely trilobate; and the foot-stalks of the flowers rising in clusters from the axillas of the leaves, each supporting one large flower of different colours in the varieties.

Varieties are] Cretan Lavatera with red flowers—white flowers—and with purplish flowers.

²LAVATERA *Trimestris*.

Spanish Lavatera] Rises with a slender, herbaceous, rough stalk, branching two feet high; trilobated smooth leaves, having oval-lanceolate lobes, the middle lobe much the longest; and pale-red flowers, singly on short foot-stalks.

Perennial Shrubby Kinds.

These have tall straight, somewhat shrubby, perennial stems, of several years duration in dry soils.

³LAVATERA *Arborea*.

Tree

Tree-Lavatera, commonly called Tree-Mallow.] Rises with a thick, strong, perennial stem, eight or ten feet high, dividing at top into many branches; large, seven-angled, plaited, soft, woolly leaves; and from the axillas, clusters of short foot-stalks, each sustaining one large purple flower, appearing in succession from June till September.

⁴LAVATERA *Triloba.*

Trilobate Shrubby Lavatera.] Rises with an upright, thick, branchy, perennial stem, the branches numerous and spreading; trilobate, and subcordate-roundish, crenated, woolly leaves; and aggregate foot-stalks, each sustaining one light purple flower.

⁵LAVATERA *Albia.*

Albian Five-lobed Shrubby Lavatera.] Rises with an upright, branching, perennial stalk, five or six feet high; large five-lobed, soft, woolly leaves; and light-purple flowers, growing singly.

The flowers of all the species, are large, composed each of five broad petals, and grow on foot-stalks from the joints of the stem and branches, in great numbers, continuing in succession from June until August or September, succeeded by plenty of seed in autumn.

The plants in general are of hardy growth, and succeed in any of the open borders; the annuals are only of one summer's duration, the perennials of several years, both in root and stem.

They are all proper ornaments for any part of the pleasure-ground.

The annuals particularly have singular beauty, their flowers being large, numerous, and conspicuous, and very proper furniture where large showey plants are required; and are easily and abundantly raised from seed in the open ground.

The shrubby kinds are also good furniture for shrubbery compartments, having large, straight, upright, durable stems, terminated by branchy bushy heads, and very large soft foliage, that form a fine variety in assemblage; though their flowers are often hid by their large leaves. These perennial kinds should have a dry soil, otherwise are apt to go off in two or three years; a fresh supply, however, may always be easily raised from seed in the common ground.

Propagation of all the Sorts.

They are propagated abundantly by seed in the open ground in the spring; the annuals

in the place where sowed, and the perennials also either where they are to remain, or for transplantation.

The annuals succeed generally best when sown where it is designed they shall flower, either in the borders, or in pots. Sow them in spring, any time from February till May, in patches, four or five seeds in each, half an inch deep; when the plants are an inch or two high, thin them to two or three in each patch, or if only one in a place, the plants will be the stronger and more branchy; the same method is to be observed in sowing them in pots.

If intended to transplant any of these kinds from one place to another, it should be done while the plants are young, about three or four inches high, for their roots being long and not very fibrey, they do not succeed so well by transplantation, as plants with more fibrey roots.

The perennials are also raised plentifully by seed in a bed or border of light earth, either in patches, as above, to remain, or may be sowed for transplantation, by broadcast, and raked in, or in shallow drills, half a foot asunder; and when the plants, sowed in either method for transplanting, are three or four inches high, plant them out at once in the places where they are to remain, or may be planted in nursery beds, to remain till autumn or spring, or till wanted.

LAURUS, Bay Tree.

This genus furnishes some eminent evergreen and deciduous trees, both for ornamental plantations and the green-house, growing from ten or fifteen to twenty or thirty feet high; garnished with largish, oblong, mostly entire leaves, and small hexapetalous hermaphrodite flowers.

Class and order, *Enneandria Monogynia.*

Characters.] CALIX, none. COROLLA, six oval, concave, acuminate, erect petals. STAMINA, nine filaments standing by threes, and small antheræ. PISTILLUM, an oval germen, single style, and obtuse stigma. PERICARPIUM, an oval, acuminate, unilocular berry, containing an oval sharp-pointed nut or seed.

There are about seven or eight species of this genus, all of them natives originally of foreign parts; the common Bay, that of the south of Europe, the others of America and Asia; and of which species three are hardy, and the rest for the green-house; of the
hardy

L A U

hardy kinds, one is a beautiful ever-green, and two deciduous, and the green-house sorts are principally of the ever-green tribe.

Hardy Ever-green Kinds.

¹LAURUS Nobilis.

Noble Ever-green Laurus, or Common Bay-tree.] Hath an upright trunk, branching on every side from the bottom upward, rising twenty or thirty feet high; spear-shaped, nervous, stiff, ever green leaves, three inches long and two broad; and small, yellowish, quadrifid, dioecious flowers; succeeded by red berries in autumn and winter. Is a native of Italy, &c. but has been long in the English gardens.

Varieties.] Broad-leaved Bay-tree—waved-leaved Bay-tree—narrow-leaved Bay-tree—striped-leaved Bay-tree.

The broad-leaved sort is often preserved in the green-house collection, but all the sorts may be inured to the open air all the year the same as the common Bay.

Hardy Deciduous Kinds.

²LAURUS Aestivalis.

Aestival, or Deciduous Bay.] Rises with an upright stem, branching eight or ten feet high, covered with a purplish bark; oblong-oval, acuminate, veined, deciduous leaves, two or three inches long, half as broad, growing opposite; and small white flowers; succeeded by red berries, but none in England. Is a native of North America.

³LAURUS Benzoin.

Benjamin-tree.] Grows fifteen or twenty feet high, dividing into a very branchy head; oval, acute, unveined, deciduous leaves; three or four inches long, and half as broad; and small yellowish flowers, not succeeded by berries in England. Is a native of North America.

From this tree is said to be procured the medical substance, called Benjamin.

⁴LAURUS Sassafras.

Sassafras-tree.] Hath a shrub-like straight stem, branching ten or fifteen feet high; garnished with both oval, and three-lobed, shining, deciduous leaves, of different sizes, from three or four to six inches long, and near as broad; and small yellowish flowers; succeeded by blackish berries, but not in England. Is a native of North America.

The wood of this tree is very fragrant, and is esteemed a great antiscorbutic; and used in

L A U

infusion, like tea, is a very powerful purifier of the blood; for which purpose great quantities of the wood is brought hither from America, and is commonly cut or rasped into chips for use. In London the infusion thereof, in the manner of tea, is sold in the saloop-shops, and about the streets, instead of saloop, or salep; but it is said that too constant use of it occasions the head-ach.

Green-house Kinds.

⁵LAURUS Indica.

Indian Bay-tree.] Rises with an upright straight trunk, branching regularly twenty or thirty feet high; adorned with very large spear-shaped, plane, nervous, ever-green leaves, on reddish foot stalks; and bunches of small whitish-green flowers; succeeded by large oval black berries; but do not ripen in England.

⁶LAURUS Borbonia.

Borbonia, or Carolina Red Bay-tree.] Rises with an upright straight stem, branching fifteen or twenty feet high; large, spear-shaped, ever-green leaves, transversely veined; and long bunches of flowers, on red foot-stalks; succeeded by large blue berries, sitting in red cups.

⁷LAURUS Camphora.

Camphora, or Camphire-tree.] Rises with a large trunk, dividing into a very branchy head, twenty or thirty feet high; spear-shaped-oval, triple-nervous, ever-green leaves; and small yellowish flowers, succeeded by black berries; but none in England. It is a native of Japan.

Every part of this tree imparts a fragrant smell of camphire, and the substance of that name is got by distilling the root and wood with water, in an alembic, having a kind of twisted straw head, thro' which the humidity evaporates, and the camphire sticks to it.

⁸LAURUS Cinnamonum.

Cinnamon-tree.] Rises with an upright, branching stem, fifteen or twenty feet high; oval-oblong, trinervous leaves; and whitish flowers in clusters; succeeded by oval berries, but none here. Is a native of India and Egypt; and it is the bark of this tree that is the cinnamon of the shops; which grows in great plenty in the Island of Ceylon in the East Indies, from whence the Dutch supply us and other European markets with that commodity.

The flowers of all the species of Laurus are small, consisting of six petals, grow usually

ally in clusters, but have no beauty; and appear in spring and summer, which in the common Bay are succeeded here by plenty of berries; but in the other sorts, rarely any seed in England.

All the species are of the tree and shrub kind, and merit admittance in every good collection. The three hardy sorts are proper for all ornamental plantations, and will succeed any where in common with other hardy trees and shrubs; and the tender kinds will exhibit a fine variety among the green-house exotics.

The *Laurus Nobilis*, noble or common Bay-tree, is indeed a noble ever-green tree, as well as a fine aromatic, has been long an inhabitant of our gardens, and is extremely proper for any of the shrubbery plantations, where, it being a lively ever-green, it will effect a fine variety at all seasons of the year. Some of the varieties of this tree are also sometimes retained as green-house plants, particularly the broad-leaved and narrow-leaved kinds, which by former botanists were considered as distinct species, but they are now found to be only varieties of the common Bay; and like that sort, may be innured to the open air all the year; remarking that even the common sort, as well as these, is apt to suffer in its young branches in very rigorous winters; therefore, if thought convenient, some of the above varieties may also be potted to have shelter in winter, and to encrease the variety of the green-house collection.

As this tree in its several varieties is apt to throw out many suckers from the bottom, so as sometimes to form a thicket, to have the trees grow with handsome straight stems, and regular heads, the suckers should be all cleared away, and those of them that are taken off with roots, if planted, will form good plants.

The other hardy kinds, deciduous Bay, and the other two deciduous sorts, the *Laurus Benzoin* and *Sassafras*, also succeed in the open ground all the year, which for their singularity merit admittance in every shrubbery; and the nature and beauty of their fine foliage will contribute exceedingly to the variety of the deciduous plantations.

The green-house kinds requiring shelter here in winter, must always be kept in pots; they are all fine plants, and should never be wanting in curious green-house collections: pot them in rich light mould, and place them in the green-house all winter, and in

the open air in summer. See GREEN-HOUSE Plants.

But the cinnamon is also sometimes retained as a stove-plant: it will, however, succeed in the open air in the heat of summer, and in a good warm green-house in winter, especially such as are accommodated with flues, &c. to have fires in severe weather.

Propagation, &c. of all the Sorts.

The common Bay is propagated by seed, layers, and suckers.

By Seed.—This should be sowed soon after the berries are ripe, or early in spring, either in beds, covering them with earth near an inch deep, or in drills half a foot asunder, the same depth; the plants will come up late the same spring; observing to supply them with frequent watering during summer, and in winter defend them from severe frost, by shelter of mats, or some other covering, they being tender while young; and after having two summer's growth in the seed-bed, then, in the spring following, transplant the strongest in nursery-rows, two feet asunder, and a foot apart in each row; giving water in dry weather, till they have taken good root, and hoe down weeds in summer. Here they may remain till half a yard, or two or three feet high, and then planted out into the shrubbery in autumn or spring.

If the berries are sowed in pots and plunged in a hot-bed in spring, it will bring the plants forwarder, being careful to innure them to the full air in summer.

By Layers.—Lay down some of the lower branches that are well furnished with young shoots; each of which shoots are to be slit-layed, to form plants: they will be rooted in one year; then in spring take them off, and plant them in the nursery as directed for the seedlings.

By Suckers.—These should be taken up with good roots in autumn or spring, and planted in the nursery like the seedlings and layers.

The propagation of the deciduous Bay, Benjamin and Sassafras-tree, is by seed, by layers, and sometimes by suckers and by cuttings. The seeds or berries are procured from America, preserved in sand; which should be sowed as soon after they arrive as possible, because they often lie a year before they germinate: sow them in a bed of light earth an inch deep, or may sow them in largish pots the same depth, plunging them in mould in an

an east border up to their rims, till spring following, and if then placed in a hot-bed, it will greatly forward the germination of the seed, and soon bring up the plants; but they must be timely innured to the full air: the young plants raised by either method, should be watered during summer, and sheltered from frost in winter, like the common Bay-feedlings; and when two years old, plant them out in nursery rows, as directed for those plants. The propagation of these two sorts by layers and suckers, is the same as directed for the Bay-tree, but it is sometimes two years before the layers are rooted.

Cuttings of them will sometimes put out roots by aid of a good hot-bed.

The green-house kinds are propagated commonly by layers, but they are often two years before they are sufficiently rooted. They may also be raised from seeds, procured from the places of their growth abroad, and sow them in pots; they rarely grow the first year, so place them in the open air in summer, and in the green-house, near the windows, in winter; and in spring place the pots in a hot-bed, which will bring up the plants, giving air daily, and frequent waterings, and innure them by degrees to the open air as the summer advances; place them in shelter in winter, and in spring plant them in separate small pots, managing them as other green-house shrubs, &c.

LAWN, a spacious open plain of grass-ground, in a garden or park, and generally made to extend immediately in the front of the mansion of a country seat.

A noble lawn of grass extended in the principal front of the habitation, adds considerably to the grandeur of the garden and scite in general, and beauty of the mansion, by laying it open to the neighbouring country, as well as admitting of extensive prospects; so that where there is scope of ground, a spacious Lawn, as large as the nature of the garden admits, should always be planned in the most conspicuous part immediately adjoining the house, and may be extended outward as far as shall be convenient, even beyond the limits of the garden, in large estates, continuing it forward to the utmost boundary of a park, or paddock, or as far as the view from the house shall extend, allowing width in proportion; having each side bounded by noble rural plantations, interspersed with serpentine walks, and open spaces both of grass and gravel, of different

forms and dimensions, for places of retirement, shade, and ornament.

The situation of a Lawn should generally be directly on the main front of the dwelling, if the nature of the ground admits; or in some cases, where there is good scope of ground, it may be continued more or less each way, but always the most considerably on the principal front, if the situation allows it, which if it fronts the south, or towards any of the southerly points, is the most desirable aspect for a complete Lawn.

The dimensions may be from about a quarter of an acre to six or eight, according to the extent and situation of the ground, and in large estates, having a park, &c. adjoining, the Lawn is often extended over ha-ha's beyond the garden, sometimes to ten, twenty, or even to fifty or sixty acres, or more.

As to figure, it is very commonly oblong, sometimes square, oval, or circular, all of which may be according to fancy, or to the figure of the ground; but somewhat of the oblong form is rather the most eligible; and in whatever figure the Lawn is designed, it should widen gradually from the house outward to the farthest extremity, to have the greater advantage of prospect; having both sides bounded by rural shrubbery plantations, as before observed; continuing the homeward part of the plantation on each side, gradually round toward each wing of the house, that company may sooner arrive in the walks of the plantation under shade, shelter, and retirement, when required; and the termination at the farther end, may be either a ha-ha, to extend the prospect, if there shall be an agreeable one; otherwise, if there is no good view beyond the extreme limits, it may terminate in a shrubbery; or if the Lawn is very extensive, and no inviting prospect beyond the extreme boundary, the termination may be a plantation of stately trees, arranged in considerable sweeps and concave curves, that the imagination may conceive the view to be swallowed up in wood. When, however, the Lawn extends towards any great road, or distant agreeable prospect, so as to command views thereof, it is more in character to have the utmost verge open, so as to admit of a grand view to the mansion.

The side boundaries of the Lawn should be formed with plantations of curious shrubs and trees, disposed in clumps, alternately deciduous and ever-greens; not in close re-

L A W

ular arrangement, but in rural disposition, in imitation of nature, in irregular elegant clumps, with irregular breaks, or opens of grass-ground between, communicating with the lawn, for views, &c. the clumps to be of different dimensions, variously formed, having some parts in grand projecting sweeps advancing toward the Lawn, others in concave curves the contrary way, all varying in their dimensions, position, and direction, to appear more rural, and to take off all stiff formal appearance, both from the figure of the Lawn and plantations; observing, as above, to plant the clumps, with deciduous and ever-green plants alternately; and place the lower growth of shrubs towards the front, and the taller backward in proportion to their several statures, so as to exhibit a regular gradation of height; that the different sorts may appear from the Lawn; and may be continued backward to some considerable depth, and backed with the most lofty trees; through the internal parts of the plantation may be gravel or sand walks, some shady, others open; with here and there some spacious grass openings, of different dimensions and figures.

The homeward part of a Lawn, however, should always have each side-verge ornamented as above, with plantations, which as the Lawn extends may gradually diminish.

Very extensive Lawns in parks or paddocks, &c. have the surface sometimes dotted with noble trees, dispersed in different parts, at great distances not to obstruct the view; some placed singly, others in groups by twos, threes, fives, &c. and some placed irregularly, some in triangles, sweeps, straight lines, and other different figures, to cause the greater variety, each group generally diversified with different sorts of trees, all suffered to take their own natural growth.

The grass of the Lawn, and other grass-ground communicating therewith, may be formed either by sowing grass-seed, or by laying with turf; but in very extensive works turfing would be very expensive, therefore seed is the most eligible; especially in that part of the Lawn which is extended beyond the garden. See GRASS.

It should always be kept perfectly neat, particularly the home Lawn within the garden, which should be often poled and rolled all the year, and in summer well mowed, once a week at least. See GRASS.

L A Y

LAYING, the propagation by layers, is particularly adapted for almost all sorts of trees and shrubs and many herbaceous plants.

The propagation by layers is effected by laying branches and young shoots of trees and plants in the earth, from two or three to five or six inches deep, leaving their tops out; and that part layed in the earth emits roots, some sorts in from two or three to five or six months, others a year, and some are two years before they are sufficiently rooted, and each layer so rooted commences a new plant, which are then to be separated from the parent, and planted in the nursery way to acquire due strength and size, for the purposes for which they are calculated. See the method of performing the operation.

Vast numbers of shrubs and trees are propagated by Layers; but is more particularly applicable to the increase of numbers of the shrub kind; because their branches grow near the ground, convenient for Laying: it may also, however, be practised with equal success on fruit-trees and forest-trees, when their branches are situated low enough for Laying; though the varieties of fruit-trees are commonly propagated by grafting and inoculation, the vine and fig, however, often by Layers; and forest-trees, for the general part, by seed, except for the continuance of varieties, then it is performed either by layers, cuttings, grafting, or budding; for plants raised by all these methods, continue exactly the same in every respect, as the parent plant from whence they were raised; for, as observed on former occasions, many sorts of plants, when raised from seed, vary so greatly, that out of numbers very few may be like the original, or parent plant, as observed under the article GRAFTING, &c. so that Laying is a certain method both to continue any approved variety, as also to encrease such shrubs or trees that do not produce seeds here, and which cannot be easily obtained; likewise is both an expeditious and plentiful mode of propagation; for by layers, many new plants are often raised in a few months, that would take two or three years to raise them the same size from seed; and in many sorts so abundantly, that all the shoots of any branch situated near the ground, or convenient for Laying, may be made each a distinct plant.

The Laying for all sorts of the tree or shrub kinds, is generally performed on the young

L A Y

young shoots of the preceding summer; layed in spring or autumn; and sometimes on shoots of the same year, in summer, especially of many sorts of hard-wooded ever green trees and shrubs, that do not strike root readily in the older wood; which is generally mentioned in the culture of the respective sorts. Though many sorts of trees having their wood of a soft loose texture, layers of them of several years growth, will often grow pretty freely; but for general Laying for most sorts, the young wood of the former year is the proper part for that operation.

But in herbaceous plants propagated by layers, such as carnations, pinks, double sweet-williams, &c. the young shoots of the same year, in June and July are commonly the most successful for layers.

The season for performing most sorts of tree and shrub Laying, is autumn and spring, though it may be performed at almost any time of the year, but the most general season is any time from October till March, only excepting, as above observed: such hard-wooded plants that are found not to succeed by the common method of Laying in the one-year's shoot, at the above season, should be layed in the same summer's shoot in June or July, while it is tender, before it becomes woody, and it will often be rooted by the end of the same summer.

Many kinds of under-shrubby and herbaceous plants will also succeed, if layed any time in spring or summer till the end of June; though June and July is the most successful for such of the herbaceous tribe, as carnations and others usually propagated by Laying: it is, however, but few herbaceous plants that are propagated by that method, it being readily effected in many sorts, to continue the varieties, by slips, off sets, or parting the roots, which is always mentioned; and by which the varieties of these kinds are continued the same as by Laying.

When intended to lay any trees or shrubs that naturally run up with stems, without furnishing any considerable quantity of lower branches for Laying, a sufficient number of strong plants should be set in the nursery, at proper distances, and headed down in autumn after, within a few inches of the ground, that they may throw out a good quantity of young shoots the following summer, convenient for Laying the succeeding autumn; or, if you wait another year, you will have many more shoots for the purpose of layers, by the first shoots

L A Y

throwing out many lateral ones, and each of which layed will form a plant; and the Layers being rooted, and all cleared away, the stool remaining will furnish another crop of shoots for Laying next year.

But when layers are required from any trees that are grown up, and whose branches are at a distance from the ground, a temporary stage or scaffold is erected, on which to place pots or tubs of mould to receive the Layers.

One general method of merely Laying the branches or shoots in the earth, is practised for all sorts, as directed below; but previous to laying, they are often prepared different ways to facilitate their rooting, according as the trees of different natures require; as by simple Laying, twisting, flitting, cutting the bark, piercing the shoot, and by wiring, &c. as follows:

By Simple Laying.—This is only simply Laying the shoots in the earth, as hereafter directed, without any previous preparation of twisting, flitting, &c. and is sufficient for vast numbers of trees and shrubs of the soft-wooded kinds: but such as do not readily root by this simple method, must have recourse to some of the following ways, and the sorts which require it is generally mentioned under their proper genera.

By Twisting the Layer.—By giving the shoot a gentle twist in the part designed to be layed, it greatly promotes and facilitates the emission of fibres from the bruised parts; and layers of numerous trees and shrubs may be forwarded exceedingly in rooting by this method.

By Slitting, or Tonguing the Layer.—This is the most universal and generally most successful mode, where any preparation of the shoot is necessary to promote its rooting; it is performed by slitting the shoot at a joint, up the middle, half an inch or an inch or more long, according to the size and nature of the Layer, forming a sort of tongue, nearly the same as directed for carnation Layers; Laying that part in the earth, and raise the top upright, or rather pointing inwards, so as to separate the tongue of the slit from the other part, and keep the slit open; then apply the earth about the Layer, as here under directed.

By Cutting the Bark.—This is done by cutting the bark all round at a joint, taking out small chips thereof all the way below the cut, and Laying that part in the earth, it will readily

readily emit roots; in some sorts more freely than by any other preparation.

By Piercing the Layer.—Thrust an awl through the shoot at a joint in several places, Laying that part, and it will emit fibres from the wounds.

By Wiring the Layer.—Twist a piece of wire hard round the shoot at a joint, and prick it with an awl on each side of the wire in several places, Laying it in the earth, it will break out into roots at the confined and wounded parts; and often proves successful to such trees and shrubs that do not readily emit fibres by the other methods.

By one or other of the above methods, almost all sorts of trees and shrubs may be propagated.

Always keep in mind that the young shoots of one or two years growth are the proper parts for Laying, either such shoots rising immediately from the bottom, properly situated for Laying; or large lower branches furnishing plenty of such shoots, should be layed down, and all the shoots on it made layers, and the following is the method to be practised for Laying all sorts.

The general method of Laying all sorts of trees or plants, either by simple Laying as above, or by any of the other above methods, in respect to the preparation of the shoots, is in the following manner: the ground round each plant intended for Laying, must be digged, and excavated for the reception of the Layers; then lay down in the earth all the shoots or branches properly situated for this purpose, peg each down with a hooked stick; laying also all the proper young shoots on each branch or main shoot; fixing each layer from about three or four to six inches deep, according as they admit, and directly mould them in that depth, leaving the tops of every layer out of ground, from about two or three to five or six inches, according to their length, though some shorten their tops down to an eye or two only above the earth; observing to raise the top of each Layer somewhat upright, especially the slit, or tongued Layers, to keep the slit part open; according as all the Layers of each plant, or stool, are thus Layed, level in all the mold finally, and equally in every part close about every Layer, leaving an even smooth surface, with the top of each Layer out, as above directed.

Sometimes the branches of trees are so inflexible as not to be easily brought down for Laying; in which case they must be splash-

ed, making the gash or cut on the upper side; and when they are grown too large for splashing, or that the nature of the wood will not bear that operation, they may be thrown on their sides, by opening the earth about the roots, and loosening or cutting all those on one side, that the plant may be brought to the ground to admit of Laying the branches.

When layers are to be made from greenhouse shrubs, or other plants in pots, the Laying should generally be performed in pots, either of their own, or others placed for that purpose.

After Laying in either of the above methods, there is no particular culture necessary, except in the heat of summer, to give occasional waterings to keep the earth moist about the layers, which will greatly forward them, and promote a good supply of roots against autumn, when those that are properly rooted should be transplanted.

We before noticed, that some sorts will be properly rooted in the autumn after Laying, and some require two years: examine them at the proper season, October and November, and let those that are rooted be cut from the main plant, with all the root possible, and plant them out in nursery rows, a foot or two asunder, according to their nature of growth, there to remain till of due size for their several purposes; but those of tender quality must be potted, and placed among others of similar nature.

When the layers are all cleared from the stools or main plants, the head of each stool, if to be continued for furnishing Layers, should be dressed; cutting off all decayed and scraggy parts, and dig the ground about them, and some fresh mould worked in close about the head, to refresh and encourage their producing a fresh supply of shoots for next year's laying.

LEGUMEN, Legum, or Pod, a species of seed-vessel, such as that of the pea, bean, kidney-bean, &c.

A Legumen, or pod, is a seed-vessel generally oblong, having two valves, or external openings, inclosing a number of seeds that are fastened along one suture only, or joinings of the valves, and differs from that kind of pod, by the botanist termed *siliqua*, by the latter having the seeds fastened to both sides of the futures. See SILIQUA.

All the papilionaceous flowered plants, have a Legumen, for their seed-vessel, exemplified

fied in the pea, bean, kidney-bean, &c. See PAPILIONACEUS.

LEUCOJUM, Great Snow-drop.

The plants are bulbous-rooted, herbaceous, flowery-perennials, proper for the open borders, rising with annual stalks a foot high, terminated by hexapetalous white flowers.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, an oblong compressed spatha opening on the side. COROLLA, is bell-shaped, spreading, and of six oval petals. STAMINA, six short bristly filaments, and four-cornered erect antheræ. PISTILLUM, a roundish germen under the corolla, obtuse, clavated style, and an erect bristly stigma. PERICARPIUM, a turbinated trivalvular, trilocular capsule, containing numerous roundish seeds.

In this genus former botanists ranged also the *galanthus*, or common winter snow-drop, by some resemblance in their flowers, but they are very different from each other, in that the flowers of *Leucojum* have six petals, and the *Galanthus* but three, accompanied by a very singular nectarium in the centre.

There are three species,—the spring-flowering—summer-flowering—and autumnal flowering, viz.

¹LEUCOJUM *Vernum*.

Vernal, or Spring Leucojum.] Hath an oblong bulbous root; sending up several flat leaves, six or eight inches long; and amidst them an upright, channelled, hollow, naked stalk, about a foot high, terminated by a spatha, protruding one or two flowers on slender foot-stalks, drooping downward; flowering in March.

²LEUCOJUM *Æstivum*.

Summer Leucojum.] Hath a large, oblong, bulbous root; crowned with several long, flat, broad leaves; and amidst them an upright, thick, hollow stalk, fifteen or eighteen inches high; terminated by a spatha, protruding many white flowers, on slender footstalks, drooping downward; flowering in May.

³LEUCOJUM *Autumnale*.

Autumnal Leucojum.] Hath a large oblong bulbous root; crowned with many narrow leaves; an upright, naked, hollow stalk; terminated by a spatha, protruding many white flowers, on long weak foot-stalks hanging downward, and very slender style; flowers in autumn.

Of these three species the two first are the most common to the English gardens.

They are all very hardy, durable in root, but annual in leaves and stalks, which arise from the root in spring, and decay in summer, &c. soon after they have flowered; but the roots abide for years, and encrease exceedingly by off-sets, which may be separated every two or three years.

Their flower-stalks rise immediately from the root, naked or leafless, and the flowers stand at top, each consisting of six oval petals, that coalesce at their base, each flower droops in a snow-drop manner, succeeded by plenty of seed.

Considered as flowery plants, they are pretty ornaments for the borders, or any of the compartments contiguous to the principal walks and home-lawns; the roots may be had at the nurseries, plant them in autumn, towards the front, in patches of three roots in each, setting them three inches deep; they will flower the following year, at their usual time; and the roots may remain unremoved two or three years, when they will be encreased by off-sets into large bunches, then should be taken up for separating the off-sets, and the largest roots planted again for flowering, and the off-sets in nursery-beds for a year or two.

Their propagation is by off-sets of the roots, as just observed, which they afford in tolerable plenty, and may be separated every third year, in summer when their leaves decay, like other bulbs. See BULBUS.

They may also be raised from seed, but the seedling plants will be three or four years before they flower. Sow it in August or September, in a border of light earth half an inch deep; the plants will rise in spring, which in the second summer should be taken up at the decay of the leaf, and planted in beds till they flower, then removed to the borders.

LIGHT. Light and air are as necessary for ennobling the principles of vegetation as for animal oeconomy.

It has been experienced that light is of such infinite service to the growth of vegetables, that it contributes exceedingly, both to facilitate their vegetation, and encrease their perfection and duration, for it is obvious that most plants are considerably more prosperous, and attain greater perfection in a free exposure fully open to the light and air, than in shady places; the same is observed of fruits. Those growing in a situation full to the light of the sun, are generally more large and fair, ripen sooner, and more perfectly, both as to beauty,

beauty, and richness of flavour, than such as grow in the shade; the above reasons, therefore, should determine us to cultivate most of our principal plants and fruits in a situation open as much as possible to the full light, and influence of the sun; though upon particular occasions in the heat of summer, a shady place may be necessary for some sorts of plants; not, however, where shaded and darkened by spreading trees, &c. but a border open above to the full light, and only shaded from the immediate rays of the sun; but for the general crops, a perfectly open, sunny, lightsome situation, free from the shade of spreading trees, is always the most eligible.

It is also observable of plants growing in garden-frames, green-houses, &c. in winter, when, in time of severe weather, covers or shutters have been obliged to be continued long over the glasses, so as to exclude the rays of light, the plants thereby, for want of light, sicken, grow pale, and assume an unhealthy appearance for a long time, the leaves often either decay or drop off; and frequently when the covers are continued very long without the admission of Light, the whole plant in many sorts gradually dwindles and perishes. Great attention is therefore requisite, in this case, when the severity of the weather obliges us to use other covers besides the glasses, to take every opportunity of a favourable day, or even an hour or two of a day to admit the light.

The same is also observable to plants in early hot-beds, such as cucumbers, melons, &c. which, early in the year, require a covering of mats over the glasses every night, that if these additional covers are applied too soon in the afternoon, and continued late in the morning, so as to keep the plants long in darkness, it is a very considerable disadvantage to their growth; as will cause them to grow weak, pale, and sickly. Let, therefore, the plants in those beds enjoy the light every day as long as possible, at least from the sun's rising to its setting, or longer, if the temperature of the heat of the hot-bed, and that of the external air shall permit; for tho' the plants in hot-beds also grow on nights when in total darkness, yet continue them so but two or three days, the difference in growth, for want of day-light will soon appear.

Light being, therefore, so beneficial to plants in general, that to encrease it as much

as possible to those in frames, green-houses, stoves, &c. it is necessary to paint the inside of all these departments white, to reflect the rays of light as much as possible, but more particularly on nights, and in the day-time when the severity of the season requires covers or shutters over the glasses.

LIGUSTICUM, Lovage.

It furnishes some tall herbaceous perennials and biennials, retained in gardens for variety and medical purposes; rising with very large, radical, many-parted leaves, and erect branchy annual stalks, some two yards high, others not half a yard, terminated by large umbels of yellow flowers of but little beauty.

Class and order, *Pentandria Digynia*.

Characters.] CALIX, umbellate flowers, having both the general and partial umbel multiple, the general involucre of seven unequal leaves, and the partial one three or four, and a small five-parted perianthium to each floret. COROLLA, each floret of the umbel have five plane petals. STAMINA, five short hair-like filaments, and simple antheræ. PISTILLUM, a germen under each floret, two styles, and simple stigmas. PERICARPIUM, none, an oblong, angular, channelled, divided fruit to each floret, containing two oblong seeds.

The most material species are;

¹LIGUSTICUM, *Levisficum*.

Levisficum, or common Lovage.] Hath a thick, fleshy, deeply-penetrating perennial root; crowned by very large, many-parted, radical leaves, with broad lobes, having incisions at top; upright, strong, channelled stalks, branching six or seven feet high, and all the branches terminated by large yellow umbels.

This is the sort commonly cultivated for use, and every part of the plant is aromatic and medicinal; good to expel wind, warm and comfort the stomach; but the seeds are rather the most material part.

²LIGUSTICUM *Scoticum*.

Scottish Lovage.] Hath a thickish, fleshy, penetrating, perennial root; crowned by large doubly-trifoliate leaves, with broad, short, indented lobes; upright, round stalks, half a yard high; terminated by smallish yellow umbels.

Both these species flower in June and July, and ripen plenty of seeds in autumn.

They are hardy plants, durable in root, but annual in leaf and stalk, though the second sort is also sometimes biennial; both sorts

forts may easily be raised from seed, and fresh plants from scattered seeds, will rise spontaneously.

Both the sorts may be admitted into large pleasure-grounds, to encrease the variety of herbaceous perennials, and the first sort also for medicine, and will prosper in any common soil and situation.

Their propagation is by seed in autumn or early in spring: sow it in any bed or border broad-cast, and rake it in. When the plants are three or four inches high, plant them out into beds of moist earth, two feet asunder, and in autumn, those intended for the pleasure-ground should be transplanted therein, but let those for medical use remain in the beds.

LIGUSTRUM, Privet.

This genus furnishes a hardy, deciduous, and ever-green shrub for the shrubbery; both varieties of one species, adorned with oblong entire leaves, and spikes of infundibuliforme white flowers, succeeded by black berries.

Class and order, *Diandria Monogynia*.

Characters. CALIX, is monophyllous, tubular, and four-parted at top. COROLLA, is monopetalous, funnel-shaped, with a cylindric tube, cut at top into four oval segments. STAMINA, two filaments, and erect antheræ the length of the corolla. PISTILLUM, a roundish germen, short style, and obtuse bifid stigma. PERICARPIUM, a roundish smooth unilocular berry, having four seeds.

Modern botanists admit but of one species, the principal of which is deciduous, and the variety an ever-green.

LIGUSTRUM Vulgare.

Common Privet;—Consists of the two following varieties:

Deciduous Privet.] Hath a shrubby stem, branching erectly ten or twelve feet high, the branches numerous quite from the bottom, slender, pliable, and tough; spear-shaped-oval, opposite, close fitting, deciduous leaves, two or three inches long; and white flowers in thick erect spikes at the ends of the branches, succeeded by clusters of black berries.

Ever-green Privet.] Hath a shrubby, stronger upright stem, branching more erectly, twelve or fifteen feet, having numerous branches quite from the bottom, of a pliable tough nature; spear-shaped, acute, opposite, dark ever-green leaves, about three inches

long, and half as broad; and white flowers, in erect spikes at the ends of the branches, succeeded by bunches of black berries.

Both these shrubs flower in May and June, the flowers make a tolerable appearance, and are succeeded by the berries, furnishing ripe seed in autumn, and frequently remain on the plants the greatest part of winter.

The flowers are of one funnel-shaped petal, separately small, but being collected into close spikes, are very conspicuous.

Both the varieties of these shrubs are very hardy, durable in root, stem, and branches, which are able to resist the severest cold with impunity, and as they branch numerously all the way from the bottom, closely garnished with leaves, and their berries remaining singularly ornamental great part of winter, renders them proper furniture for ornamenting the common shrubbery-compartments in assemblage; but the ever-green kind has the greatest claim to esteem, though both sorts merit admittance in the shrubbery collection, to encrease the variety; hardly any situation or soil comes amiss to them, either in open or shady places, even under the shade of other trees; and in the midst of great towns and cities, particularly the deciduous kinds, as is evident in London, where vast quantities are brought to the markets, and hawked about the streets, which are ready sale, for the inhabitants to ornament their small gardens, courts, and balconies.

These shrubs are also often employed to form hedges in gardens, for which purpose, as they are closely branched to the very bottom, and thickly set with leaves, they are tolerably well adapted, and may be made to form a close handsome hedge; but would advise the ever-green kind to be principally chosen for this use. See HEDGES.

The propagation of both sorts is by seed, suckers, layers, and by cuttings; all in the open ground.

By Seed.—Sow the seed in October, November, or December, in a bed of common earth, an inch deep, or in drills that depth; or, as they do not grow the first year, they may be buried till next autumn, in pots in the ground, as practised for haws, and then sowed as above. When the plants come up keep them hand-weeded, and when a year or two old, plant them out in nursery rows to remain two or three years, then transplanted for good where wanted.

By Suckers.—Great plenty of suckers rise annually from the roots, which may be taken up in autumn, winter, or spring, with roots, and planted in the nursery as above.

By Layers —Lay down some of the pliable young branches in the earth, in autumn or winter, and they will be well rooted by autumn following; then cut them from the stool, with their roots, and plant them in the nursery for two or three years.

By Cuttings.—In autumn plant cuttings of the young shoots, eight or ten inches long, in a shady border, they will be properly rooted by next autumn, then plant them out in nursery rows, to remain till winter.

LILIACEÆ, *Liliaceous Plants*, plants whose flowers resemble those of a lily.

Liliaceous plants are such as have six regular petals, in the form of a lily; or three, or even one petal deeply divided into six segments, and assume a lily-flower form; all Liliaceous plants, however, have not flowers so large as the *Lilium*, some being considerably smaller.

As the *lilium*, or common lily, have no calix, several of the Liliaceous flowers are also destitute of a cup; and several have cups, which are all principally of that sort of cup called a spathe.

The following are the principal Liliaceous plants, distinguishing those without, and those with cups, or spathes.

Without Cups.—*Lilium*, or common lily, all the sorts—tulip, all the kinds—fritillary, and crown imperial—hyacinth—star of Bethlehem—bastard star of Bethlehem—tuberose—asphodelus—squill—hemerocallis, or day-lily—anthericum, or spiderwort—aloe—yucca, or Adam's needle—gloriosa, or superb lily.

With Spathes, or Cups.—crocus—galanthus, or common snow-drop—leucojum, or great snow-drop—daffodil, narcissus, and jonquil—crinum, or asphodel lily—colchicum—iris, or flower-de-luce—hæmanthus, or blood-flower—gladiolus, or sword-lily—Virginia spider-wort—amaryllis, including the Guernsey lily, belladonna lily, and Jacobæa lily, &c.—pancratium lily.

The greater part of all these Liliaceous plants of both classes are bulbous-rooted; some, however, have tuberous, and some fibrous roots; and all of them perennial in root, but annual in stalk.

They all produce ornamental garden-flowers, and most of them hardy enough to grow in

the open ground; some for the green-house and stove.

The culture of each sort, &c. is fully directed in their proper genera.

LILIUM, Lily.

This genus furnishes a beautiful collection of bulbous-rooted, herbaceous, flowery perennials, of majestic growth, all proper for ornamenting the pleasure-garden; rising with erect annual stalks, three or four feet high, garnished with long narrow leaves, and terminated by noble clusters of large, bell-shaped, hexapetalous flowers, of exceeding beauty.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, none. COROLLA, is large, bell-shaped, and of six long petals, narrow at the base, but widening gradually upward, in some sorts erect, in others turned quite back, each of thick substance, keel-formed on the back, and a nectarium forming a longitudinal line behind near the base. STAMINA, six long subulate filaments, and oblong incumbent antheræ. PISTILLUM, an oblong cylindric, six-furrowed germen, and a cylindric style the length of the corolla, and a thick triangular stigma. PERICARPIUM, an oblong six-furrowed, trivalvular, trilocular capsule, filled with semi-orbicular seeds lying over each other, in a double order.

This genus retains all the varieties of White Lily—Orange Lily—and Martagon Lily; this latter is very distinguishable from the two former, by having the petals of the corolla, revolute, or rolled back; but see each under its distinct head.

White Lily Kinds.

Of these kinds there is only one species, but which comprehends several beautiful varieties, and the common White Lily, found in most gardens, is parent of them all, and all of which have large, white, scaly, bulbous, perennial roots, crowned with leaves from autumn till summer, and sends up flower-stalks annually, terminated by the flowers, which in all the varieties are pure white, tho' with some variations.

LILIUM *Candidum*.

White Lily; of which there are the following varieties.

Common White Lily.] Hath a large squamous, bulbous root; crowned by a cluster of long

long broad leaves, close to the ground, remaining all winter and spring; amidst them an upright firm flower-stalk, a yard or more high, garnished with many narrow leaves placed irregularly; and terminated by a long cluster of large open bell-shaped, pure white flowers, one above another, having the inside of the petals smooth.

Varieties of this are] Common white Lily with striped leaves—with purple-striped flowers—double-flowered.

The two following are also supposed to be varieties only of the common white Lily, differing from it principally in that the above kinds have generally erect flowers, and these have dependent or drooping flowers, and some other variations, as in their descriptions, viz.

Dependent White Lily of Constantinople.] Hath a large scaly bulbous root; with leaves and flower-stalks like the parent sort, only the stalk is more slender, the flowers smaller, and generally growing in a dependent or drooping position.

Dependent, broad-stalked, most-floriferous white Lily of Constantinople.] Hath a bulbous root, and leaves like the other; but the stalk large, broad, and flat, sustaining at top, a large bunch of pendent flowers, from fifty or sixty to a hundred in number.

All the above varieties are by modern botanists arranged as varieties only of the *Lilium Candidum*, or common white Lily, obtained by the effects of culture; and that by continuing to encrease them by off-sets of the root, they will all retain their differences; and by seed more varieties may be gained.

They have all great merit in the beauty of their flowers, which have also great fragrance, particularly all the single-flowered kinds; but the double sort having often such a multiplicity of petals as to exclude the stamina and antheræ, the parts from which the effluvia proceeds, that they are frequently destitute of fragrance. All the sorts, however, demand attention as flowery plants, and are all so exceeding hardy as to prosper in almost any soil and situation without trouble; and if intermixed with each other, and the other species of this genus, they will exhibit a delightful variety, in the beauty of their elegant flowers; and the striped-leaved variety merits double esteem, for being not only ornamental in its flowers, like the others, has great singularity in its finely-striped leaves which being long, broad, and elegantly striped

with yellow, spreading all around flat on the ground, and abiding, appear exceedingly ornamental, but more conspicuously so in winter and early spring.

They all flower in June and July, and their stalks decay in August, when the roots remaining for some little time at rest, is the only proper period for taking up the bulbs, when necessary, as hereafter observed.

Orange-Lily Kind.

This furnishes only one species, but which, like the former, is prolific in some eminent varieties; all with large, roundish, scaly, bulbous, perennial roots; crowned with leaves in spring that decay in autumn and winter; and annual flower-stalks terminated by the flowers, which are universally of a reddish, or orange-colour, some more fiery than others.

²*LILIUM Bulbiferum.*

Bulbiferous, or Bulb-bearing Lily.—Of which there are the following varieties:

Common Orange Lily.] Hath a large squamous bulbous root; an upright firm flower-stalk, rising three feet high; very closely garnished with oblong, narrow, rigid, dark, shining leaves, placed irregularly; and the top crowned by a cluster of large, open, bell-shaped, erect-growing, orange-coloured flowers, rough within.

Varieties of this] With double flowers—with variegated leaves—dwarf-stalked.

All these sorts flower in June and July very conspicuously, and their stalks decay in August or September, when their roots remain at rest for two months, which is the time for removing them, when necessary, either to separate the off-sets, or transplant the main roots from one place to another.

They are all very hardy, and will thrive almost any where, no soil comes amiss to them, and grow freely either in open situations, or under shade of trees, or in towns among buildings, &c.

The stalks of these sorts remain fully adorned with leaves till the decay of the flowers, &c.

Bulbiferous Fiery Lily.] Hath a scaly bulbous root; an upright firm flower-stalk, half a yard or two feet high; garnished with narrow leaves, placed scattering; and bearing bulbs at the joints; and terminated by smaller upright, bright flame-coloured flowers.

Varieties of this] Greater broad-leaved bulbiferous Lily—many-flowered bulbiferous Lily—small bulbiferous Lily—hoary bulbiferous Lily.

All these bulbiferous kinds flower ornamentally in May and June, at which time all the sorts bear many small bulbs on their flower-stalks, which are embryo plants, and if taken off when the stalks decay, and planted in any bed or border, they will readily grow, and flower the second year. All the sorts, however, encrease also abundantly by off-sets of the root, and may be taken off in autumn, as observed above for the Orange Lilies.

These sorts are also all as hardy as the Orange Lilies, and will grow in any soil and situation.

Martagon Kinds.

There are several species, all of which differ from the white and orange Lily kinds, in having the flowers reflexed, and the petals of the corolla revolute, or rolled quite back; they have all large, scaly, bulbous, perennial roots; leaves and flower-stalks rising annually in spring, surmounted by many flowers, generally in a reflexed or drooping position, and with all their petals turned back toward the stalk.

³LILIUM *Martagon*.

Old Purple Martagon, or Turk's Cap.] Hath a large squamous bulbous root; upright flower-stalk, three or four feet high, garnished with broadish leaves, in whorls, and terminated by large loose spikes of purplish, black-spotted, reflexed flowers, with revolute petals.

Varieties.] Double flowered old Martagon—red old Martagon, with hairy stalks—imperial old Martagon, with divided stalks.

This species and varieties have been long inhabitants of our gardens; they all flower in June, have a good appearance, but impart a disagreeable odour.

⁴LILIUM *Pomponium*.

Pompony Martagon.] Hath a large scaly bulbous root; an upright flower-stalk, three or four feet high; garnished with narrow awl-shaped leaves, placed sparsely; and the top terminated by many reflexed, bright-red flowers, having revolute petals.

Varieties.] Pompony double red Martagon—white pompony Martagon—double white Martagon—red spotted Martagon—white-spotted pompony Martagon—yellow

pompony Martagon—yellow-spotted pompony Martagon—early scarlet Martagon—major scarlet pompony Martagon.

All these pompony Martagons flower in June, and make a fine appearance, their flowers being large and numerous.

They are hardy, grow freely any where, and may be propagated plentifully by off-sets when their stalks decay.

⁵LILIUM *Chalcedonicum*.

Chalcedonian Scarlet Martagon.] Hath a large bulbous root; an upright thick flower-stalk, three feet high; closely garnished with broad spear-shaped leaves, placed irregularly; and terminated by several large, reflexed, bright-scarlet flowers, with revolute petals.

Varieties.] With deep-scarlet flowers—with purple flowers—with large bunches of flowers.

They all flower in July, and make a very fine appearance; will grow any where, and multiply fast by off-sets of the root.

⁶LILIUM *Superbum*.

Superb Great Yellow Martagon.] Hath a large, scaly, bulbous root; strong upright stalk, four or five feet high; garnished with broad, spear-shaped, sparsely leaves; and terminated by numerous, large, reflexed, revolute, yellow flowers, in a pyramidal cluster; flowers in June or July.

This makes a noble appearance, and is worthy of a place in every collection.

⁷LILIUM *Canadense*.

Canada Spotted Martagon.] Hath a large scaly bulbous root; an upright strong stalk, rising four or five feet high; garnished with oblong pointed leaves, in whorls; and terminated by numerous, large, bell-shaped, reflexed, yellow flowers, spotted with black, having the petals scarcely revolute.

This flowers in August, is a fine majestic plant, and makes a grand appearance during the time of its blow.

Variety.] With deep yellow flowers.

All these seven species of *Lilium*, and respective varieties, are universally bulbous in root, as before observed, very large, composed of numerous squamæ, or scales, encrease considerably by off-sets, and are all perennials; but are annual in stalk, which always rise directly from the root in spring, crowned immediately with the flower buds, which in all the sorts, stand naked without any sort of calix or cup; each flower is large and of six oblong petals, blowing in perfection principally in June, July, and August, succeeded

ceeded by seed in autumn; then the stalks decay, and the roots cease to grow for some space of time that season; which period of rest, before the bulbs begin again to grow, is the proper time to remove them, when necessary, either to separate the off-sets for encrease, or to transplant the main roots into another place, or to take them up for sale, &c.

They all demand esteem as plants of ornament for the beauty of their flowers, which are strictly noble, and some of the grandest that adorn our gardens, though on account of their commonness and easy culture, are rather disregarded; but even the most common sorts of them claim attention as flowery plants, as for instance, the white Lily, very common in most places; is nevertheless a very elegant flower, it adorning the top of the stalk in a vast cluster of pure snowy white flowers, that wheresoever situated, it distinguishes itself singularly ornamental, and diffuses a fragrant odour all around. All the others possess also a proportionable degree of beauty and value for the embellishment of the pleasure ground. Therefore all the species and respective varieties, are proper ornaments for every compartment of the pleasure-ground; and if the different sorts are properly intermixed, they will effect a most elegant variety, succeeding each other in blow, upwards of three months; observing if any sorts are wanted particularly for shady or close places, the common white Lily, orange Lily, and common Martagons, are the most eligible, for they will thrive under trees; and the orange Lily also often in small gardens in the midst of buildings, in towns and cities; but besides planting all the sorts for the beauty of their flowers, I would advise to have many of the striped-leaved white Lily placed towards the fronts of the most conspicuous compartments, for the beauty also of its leaves in autumn, winter, and spring, as already observed, which, if disposed alternately with the common white Lily, whose leaves are entirely green, they will exhibit the more striking variety.

One method of planting and general culture is the same for all the sorts.

The proper time for planting and transplanting them is in autumn, when their flowers and stalks decay, which is generally in August and September, the roots being then at rest for a short space of time, which

is the only proper season for removing them, and for procuring roots to plant; though the bulbs taken up at the above season of rest, may be kept out of ground, if necessary, till October or November: the white Lilies, however, do not succeed if kept long out of the earth, and all the others succeed best when planted again as soon as possible. The bulbs of all the sorts are sold at the nurseries; their prices are very reasonable, and the most proper time to apply for them is from the end of August till October, as above noticed.

Plant them singly in different parts of the borders, and towards the front of the principal shrubbery clumps; placing them four or five inches deep, and at good distances from one another, observing to mix the different sorts in the alternate way; that is, plant first a white, next an orange Lily, &c. stationing some forward, others more back in the several compartments to effect the greater show of variety.

After being planted, none of the sorts require any particular culture, for they will endure all weather at every season; so no more is necessary than destroying weeds among them by hoe, and as some of them run up with pretty tall slender stalks, they, if supported with sticks to preserve effectually their upright position, their flowers will always appear to the best advantage.

They may all remain undisturbed two or three years, or longer, nor indeed is it proper to remove these sorts of bulbs oftener, for by remaining they flower stronger after the first year, and having encreased by off-sets into large bunches, many stalks will rise from each bunch of roots, so as to exhibit a large cluster of flowers; it is, however, proper to take up the bulbs entirely every three or four years at least, at the decay of the stalk, to separate the encreased off-sets both for propagation, and to disburthen the main roots, and give them room to take their proper growth.

Observe, that when designed to remove any of these kinds of bulbs, the proper season for it is in summer and autumn, July, August, and September, when their flower-stalks decay, and the bulbs done growing, before they begin again to emit fresh fibres below, and to form any shoot at top, after which effort of growth, it is improper to remove them that season, which would prevent their flowering the following year, and some sorts probably

Probably not the year after in due perfection, for it weakens those large kinds of bulbs considerably when removed at an improper season; mark, therefore, the above mentioned time for removing the roots of all these species: for when having done their year's growth, at the decay of the flower and stalk, they become inactive for some time, not drawing any nourishment, and at which period they may be safely removed; but as some sorts very soon begin again to emit new fibres at bottom, and form the shoot of the future leaves and flowers, which is particularly the case of all the white Lily tribe; so that when necessary to remove the roots, observe the proper time, as above, and never remove any of the sorts after they have begun to shoot again, if you would insure the next year's bloom and prosperity of the bulbs. I would, however, remark, that as some sorts, such as the orange Lily kinds, &c. do not begin to push new leaves till towards spring, the roots may more safely be removed, if necessary, any time from the decay of the flower and stalk, till toward Christmas: but would observe on the other hand, that the sooner the removal or planting is performed after the decay of the stalk, the better; for all bulbs planted early in autumn, flower stronger than such as are planted a month or two later. See **BULBUS**.

Such bulbs, however, which are removed at the proper period of rest may, if occasion require it, be kept out of ground a month or two, especially in dry sand or moss, or the like, to keep them from drying and shrinking by the air; but the retention of these roots long out of the earth, should only be practised, either when necessary to keep them for sale, or to send to any distance, or that the ground is not ready for their reception, and such like occasions; though they should never be kept out of ground longer than October, or November at latest; the white Lily kinds in particular, should be kept but as short a time as possible above ground.

Propagation of all the Sorts.

The propagation of all the sorts is most commonly by off-sets of the root; they may also be raised from seed to obtain new varieties.

By Off-sets.—All the sorts of these roots yield off-sets abundantly every year, which when greatly wanted for propagation, may be taken off annually in autumn, otherwise

once in two or three years, according as they are wanted; and the proper time of the year is in summer and autumn, when the flower is past and the stalks decayed, as observed above; observing, that in order to separate the off-sets properly, the whole should be taken up, and all the off-sets, small and great, separated from the main bulbs: the small off-sets should then be planted in beds a foot asunder, and three deep, to remain a year or two; and the large bulbs should be planted again in the borders, &c. singly; the off-sets also in the nursery beds, after having obtained size and strength for flowering in perfection, may be planted out where wanted.

By Seed.—This is sometimes practised, but more particularly for the Martagons, to obtain more varieties. In autumn, soon after the seed is ripe, sow it in pots or boxes of rich light earth, half an inch deep; place the pots in a sheltered situation all winter, and the plants will appear in the spring; when in April remove the pots to have only the morning sun all the summer, giving moderate waterings; in August transplant the bulbs into nursery-beds in flat drills an inch deep, and three or four asunder, but as the bulbs will be very small, scatter the earth and bulbs together in the drills, and cover them with earth the above depth; and having growed here till August or September following, transplant into another bed, placing them eight or nine inches each way asunder, here to remain to show their first flowers, then transplant them finally into the pleasure-ground.

LINUM, Lint, or Flax.

This genus consists of herbaceous annuals and perennials of erect growth, proper both for valuable oeconomical uses, and to form variety in gardens. The common flax being a most valuable annual for field culture, for the bark of its stalks to make linen, and its seeds linseed-oil; and some of the perennials serve to adorn the pleasure-ground; all of them rising with erect stalks from about two to four or five feet high, garnished with narrow leaves, and terminated by small funnel-shaped quinquepetalous flowers.

Class and order, *Pentandria Pentagynia*.

Characters.] **CALIX**, five spear-shaped permanent leaves. **COROLLA**, is funnel-shaped, consisting of five oblong petals. **STAMINA**, five awl-shaped filaments, and arrow-shaped antheræ. **PISTILLUM**, an oval germen, five filiforme styles, and reflexed stigmas.

stigmas. PERICARPIUM, a globular, pentagonal, quinquevalvular, decemlocular capsule, having one oval plane seed in each cell.

There are many species, but not more than one proper for oeconomical uses, which is the common Flax, an annual; and one sometimes cultured in gardens for variety, a perennial.

¹LINUM *Usitatissimum*.

Most Useful, or Common Cultivated Annual Flax.] Hath a taper fibrey root; upright, slender, unbranched stalk, two feet and a half high; garnished with narrow, spear-shaped, alternate, grey coloured leaves; and the stalk dividing into foot-stalks at top, terminated by small, blue, crenated flowers, in June and July; succeeded by large round capsules of ten cells, containing each one seed.

This may be said to be one of the most valuable plants in the whole vegetable kingdom; as from the bark of its stalks is manufactured the Flax, or Lint, for making all sorts of linen cloth; from the rags of the linen is made paper; and from the seeds of the plant is expressed the linseed oil, so useful to physicians as well as painters, and other trades.

The plant is annual, and is raised in fields like corn. See its *Culture*.

²LINUM *Perenne*.

Perennial Siberian Flax.] Hath a fibrated perennial root, sending up annually several upright annual strong stalks, branching four or five feet high; garnished with small, narrow, spear-shaped, alternate, dark-green leaves; and terminated by umbellate clusters of large blue flowers in June, succeeded by seeds in autumn.

Both these species of *Linum* are hardy, the first is but of one year's duration, the second of many by the root, but is annual in stalk.

The first is cultivated in fields for the uses before observed, but rarely in gardens, except a few plants in patches for variety; it rises from seed in spring, shoots up into stalk gradually arriving to its full height in June and July, and having stood to perfect its seed, is then pulled and prepared for use.

The perennial sort is proper furniture for any of the large borders, or other parts of the pleasure garden to encrease the variety.

Propagation of both Sorts.

The propagation of both these plants is by seed in spring; the common sort is sowed in fields, as hereafter directed; and the peren-

nial sort in a bed or border of common garden-earth, in shallow drills six inches asunder; and when the plants are two or three inches high, thin them to the same distance, and in autumn may plant them out where wanted, where they will abide by the roots many years, producing new stalks every spring.

But with respect to the general culture of the common Flax, this is raised in great quantities in fields in many places, both for the sake of its stalks to afford the flax for linen, and its seeds for oil, as above noticed.

It should have as good ground as possible, and this prepared for the reception of the seed, by proper repeated ploughings, and harrowings, to render the soil fine, and the surface even; and March and beginning of April is the season for sowing it: about two bushels is the proper quantity for an acre. It may be sowed either broad-cast, and harrowed in with a light harrow, or may be sowed in shallow drills eight or ten inches asunder, though the former is the most expeditious method; but by having it in drills, the ground can be readily hoed to destroy weeds, and which by loosening the ground, will prove also very beneficial to the crop of Flax, nor will the plants be liable to be trodden down as when they grow promiscuously.

Weeds, however, must at any rate be kept down, either by repeated hand-weedings, or by hoeing, as shall be convenient, which should be strictly attended to while the plants are young, and until they are grown above the reach of the weeds.

In the middle or latter end of August, the plants will be arrived at full growth, begin to turn yellow at bottom, and brown at top, and their seeds ripen, it is then the proper time to pull them, though if it was not for the sake of the seed, they might be pulled a little before the seeds ripen, whereby the Flax is generally better coloured and finer; but if suffered to stand till the seeds are fully ripe, it is commonly stronger, somewhat coarser and more in quantity. It should be pulled up by handfulls, roots and all, shaking off all the mould; then either spread them on the ground by handfulls, or bind them in small bunches, and set them upright against one another, for ten days or a fortnight, till they are perfectly dry and the seed ripened; then should be housed, and the seeds threshed out; winnowed and properly dried in an airy room, and then put up for use; the flax should then be rippled and sorted, and afterwards carried to

to a pond or canal of water, and laid to steep, covering it down with straw hurdles, or the like, laying stones on them; and are to remain till the stalks become brittle, and the bark or rind, the useful part, separate readily from the reed; it is then properly steeped, when it must be taken out and spread by handfulls in swaths to dry, turning it occasionally till properly bleached and dried, and it is then ready for the flax dresser.

LIQUIDAMBAR, Sweet Gum-tree.

This genus furnishes two beautiful deciduous trees for ornamental plantations, growing thirty or forty feet high, forming fine pyramidal heads, adorned with large angular and oblong leaves, and monoecious apetalous flowers.

Class and order, *Monoecia Polyandria*.

Characters.] **CALIX**, male and female apetalous flowers, apart on the same tree, the males numerous in conical loose catkins, and females in a globe, at the base of the male spike; the males having a four-leaved involucre, which in the females is double; and each floret a bell-shaped proper cup. **COROLLA**, both male and female florets are apetalous. **STAMINA**, numerous short filaments, incorporated in a body; and didymous, four-furrowed, bilocular, erect antheræ. **PISTILLUM**, an oblong germen, two subulate styles, and recurved downy stigmas. **PERICARPIUM**, many unilocular, bivalvular capsules, collected into a globular ligneous body, having many oblong seeds.

There are but two species, both of America, but very hardy trees, of the deciduous tribe, and are singular for producing a liquid, transparent, gummy substance of great fragrance.

¹**LIQUIDAMBAR** *Styraciflua*.

Styraciflua, or *Maple-leaved Virginia Liquidambar*.] Rises with an upright straight stem, and regular branchy head, thirty or forty feet high; palmated-angulated leaves, of five serrated lobes; exuding a glutinous fragrant substance; and saffron-coloured flowers in amentums at the ends of the branches in April; succeeded by large roundish fruit, having many protuberances.

²**LIQUIDAMBAR** *Asplenifolia*.

Spleenwort-leaved Canada Liquidambar.] Rises with an upright stem, branching twenty or thirty feet high; oblong leaves, sinuated on the edge alternately very deep; and saffron-coloured flowers in amentums, succeeded by roundish fruit.

Both these trees have great merit for the embellishment of the shrubbery plantations, in assemblage with others of the deciduous tribe of similar growth; and being handsome straight-growing trees, forming fine heads, attaining their proper height in this country, are also well adapted for planting detached as single objects in spacious grass opens to display their fine pyramidal growth; in which they will appear very ornamental, and by emitting their odoriferous particles, will perfume the circumambient air in summer.

They prosper in any common soil and situation, and endure our severest cold without injury.

Both the sorts are retained in the nurseries for sale, but the first is the most common.

Their propagation is by seed, and by layers, in the full ground.

By Seed.—The seed arrives from America in spring, when it should be sowed as soon after as possible, in a bed of light earth, half an inch deep, and the plants will rise some the same year, others probably not till the spring following; indulge them with moderate waterings occasionally; keep them clean from weeds all summer, and give protection from severe frost, the first two winters; and when two years old, plant them out in spring in nursery rows, two feet asunder, to remain three or four years, or till wanted for the shrubbery, &c.

But some persons sow the seeds in pots, &c. in order to move to different situations as the season requires; and that if the plants should not come up the same year, the pots may be plunged in a hot-bed the spring following to forward them.

By Layers.—In autumn lay the young shoots of the preceding summer, by slit-laying, &c. and they will most of them be rooted by autumn following, though in a dry hungry soil they are sometimes two years before they are sufficiently rooted for transplantation.

LIRIODENDRON, Tulip-tree (*Tulipifera*).

One large hardy deciduous tree, of North America, for ornamental plantations, constitute this genus, adorned with large, broad, lobated leaves, and hexapetalous liliaceous flowers, fancied to resemble the form of a tulip; hence the name Tulip-tree.

Class and order, *Polyandria Polygamia*.

Characters.]

Characters.] CALIX, a two-leaved involucre, and three-leaved inner cup, all deciduous. COROLLA, is bell-shaped, and consists of six petals, in two series, obtuse and channelled at the base, the outer three are deciduous. STAMINA, numerous linear filaments, having narrow antheræ fastened longitudinally to their sides. PISTILLUM, numerous germina formed into a cone, no style, but a globular stigma crowning each germen. PERICARPIUM, none, numerous seeds collected imbricatumwise into a sort of cone.

There is but one known species, which formerly was termed *Tulipifera*; but is now changed by Linnæus to *Liriodendron*, from the fancied resemblance of its flower to a lily, whence it might with as much or more propriety be called Lily-tree as Tulip-tree.

LIRIODENDRON Tulipifera.

Tulip-tree.] Rises with an upright large trunk, branching irregularly forty or fifty feet high; large lobated alternate leaves, of three lobes, the middle one truncated, those of the sides rounded; and from the ends of the branches bell shaped flowers, composed of six petals in a double series, spotted with green, red, white, and yellow; appearing ornamentally in July, succeeded by large conic fruit, not ripening in England.

Some of these trees have acquired a large size and stature in England, and produce flowers, which they never effect till of some considerable age and bulk; the trunk is covered with a grey bark, and the younger wood of a blueish or brownish colour, commonly very pithy, and when broken, emits a strong aromatic odour, and the leaves are of singular structure on long foot-stalks. In America some of these trees are thirty feet in circumference, with large very unequal and irregular boughs; and the timber is of great use in its native soil, particularly for making that kind of boat called periaugues, which are formed of the trunk, excavated or hollowed.

This curious tree grows freely here in the full ground, and is proper for our ornamental plantations, stationing them with the deciduous kinds of similar growth; is also very proper to exhibit singly in large lawns and other spacious opens of grass-ground.

It is cultivated for sale in all the nurseries.

Its propagation is by seed.—This is imported annually from America, which may

be had of the seed-dealers in spring; and is then to be sowed in the full ground, in beds of light earth, placing the seed length-wise, and cover it near an inch deep; they will come up the same year in May; observing to give water in dry weather, and if the bed is arched over with hoops, to have occasional shade from the mid-day sun in scorching weather, it will prove very beneficial to the germination of the seeds, and growth of the young plants, being also careful to continue the waterings occasionally during the summer; and in the winter, if you allow them shelter of mats in frosty weather, it will effectually preserve their tops, which being sometimes a little tender the first year, are apt to suffer by frost; however this covering is not always absolutely necessary, for I have observed them stand very well without any. When they are two years old, plant them out in spring in nursery-rows, two feet distant, and a foot asunder in each row; there to remain a few years, till from three to six or eight feet high, then transplanted where they are always to stand.

LOBELIA, Cardinal flower (Repuntium.)

It consists of herbaceous and undershrubby erect flowery perennials for the pleasure-garden and hot-house, rising with erect stalks from about two to five or six feet high, ornamented with oblong, oval, and spear-shaped, simple leaves; and ornamental spikes of beautiful, monopetalous, somewhat ringent, five-parted flowers.

Class and order, *Syngenesia Monogamia.*

Characters.] CALIX, is small, monophyllous, quinque-dentate, and growing round the germen. COROLLA, is monopetalous, a little ringent, and with a long cylindric tube, and five-parted limb, the two upper parts smallest, and form the upper lip, and the other largest and spreading. STAMINA, five subulate filaments, having syngenesious antheræ. PISTILLUM, an acuminate germen under the corolla, cylindric style, and obtuse hairy stigma. PERICARPIUM, an oval bilocular capsule, opening at top, and numerous small seeds.

There are many species, but not more than three or four commonly cultivated, two hardy herbaceous kinds for the open ground, and two shrubby plants for the stove.

Hardy Herbaceous Kinds.

These are fibrous-rooted, erect-growing perennials, natives of North America, but have

have been long retained in the English gardens for the beauty of their flowers.

¹*LOBELIA Cardinalis.*

Common Cardinal Flower.] Hath a thick, fibrated, milky, perennial root; crowned with lanceolate, ferrated, radical leaves; upright, firm, round stalks, rising two feet high; garnished with spear-shaped, sawed, alternate leaves; and terminated by long spikes of beautiful scarlet flowers, in July and August.

²*LOBELIA Siphilitica.*

Siphilitic Blue Cardinal Flower.] Hath a thick, fibrated, perennial root; crowned with oval, lanceolate, crenated, radical leaves; upright firm stalks, half a yard high; garnished with leaves like the radical ones; and from the axillas, pale-blue flowers, with reflexed cups; appearing in July.

Varieties.] With deep-blue flowers—violet-coloured flowers.

Both these species flower very ornamentally, and the flowers numerous in long spikes; which in dry warm seasons, are succeeded here by ripe seeds in autumn.

They are hardy enough to succeed in the full ground all the year in a dry warm soil, though as being liable to suffer by severe frost a share of them should be retained in pots for moving to shelter of a frame in frosty weather.

Tender Shrubby Kinds.

³*LOBELIA Plumierii.*

Plumier's Shrubby Lobelia.] Hath a shrubby, somewhat succulent stalk, rising five or six feet high; oval-oblong entire leaves, placed alternate; and from the sides of the stalk, white flowers, growing by two or three together on long foot-stalks.

⁴*LOBELIA Surinamensis.*

Surinam shrubby Lobelia.] Hath a shrubby stalk, rising half a yard high; oblong, serrated, smooth leaves; and flowers from the axillas on very long foot-stalks.

⁵*LOBELIA Pinifolia.*

Pine-tree-leaved Shrubby Lobelia.] Hath a shrubby stalk, rising a yard high; linear entire leaves in clusters; and blue flowers from the sides of the stalks.

The flowers of all these species of Lobelia consist only of one petal, cylindrically tubular below, and divided at top into five parts, see the *Characters*; those of the herbaceous kinds are sometimes succeeded here by seeds, but rarely any of the others.

The two first species are very ornamental flowery plants, for the principal compartments of the pleasure-garden; but being but moderately hardy, liable to suffer by severe frost, it is proper to keep some also in pots to move to occasional shelter in frosty weather, they produce extremely showey garden-flowers; more particularly the *Lobelia Cardinalis*, in its beautiful scarlet spikes, occupying half the length of the stalks, consisting of numerous flowers; but both the sorts make a fine appearance for a month or six weeks; so both demand a place in every curious collection, to encrease the variety of herbaceous flowery perennials, and for which purpose they have been long retained in most of our eminent gardens, and are kept in all the nurseries for sale.

The other three tender shrubby sorts being natives of the hot parts of America, Asia, and Africa, require a hot-house here, so must be kept in pots, and retained in that department, the first of them as the most common in the English gardens.

Propagation.

The two hardy herbaceous kinds are propagated by seed, cuttings of their stalks, and by parting their roots.

By Seed.—They rise from seed one year, and flower the next, and abide several years. Sow the seed in autumn, or early in spring in a warm border, or in pots or boxes to move to different situations in different seasons, to have shelter from frost, and shade from the mid-day sun in summer, &c. observing those sowed in autumn generally come up more freely the following spring than those which are sown in that season; allow shelter in hard frosts, as just observed, either under a frame, or awning of mats, but should be fully exposed in all mild weather; giving occasional watering in spring and summer. When the plants are come up two or three inches, prick them out in separate small pots of rich earth, give water, and place them in the shade till fresh rooted, repeating the waterings occasionally in hot dry weather, and shift them into larger pots as they shall require; in winter move them into a frame to have occasional shelter from inclement weather; and in spring, in March, some of them may be turned out into the full ground, when they will flower the ensuing summer; and some may be retained in pots to move to shelter in winter, to be as a reserve in case those

those in the open air should be killed by frost; these will also flower at their usual time in summer.

As these beautiful plants generally flower in the greatest perfection in the first and second year of their bloom, it is proper to raise a supply of new plants every year or two, in order to have them to flower in their utmost perfection annually.

By Off-sets.—Both these hardy sorts sometimes afford off-sets for young plants from their sides at bottom, which may be separated in autumn, and potted, and managed as for the seedlings.

By Cuttings.—In June, if some of the young stalks are divided into lengths of five or six inches, planted in an easterly border, two parts of three deep, covered down with hand-glasses, and watered occasionally; they will emit roots, and form young plants in a month or six weeks; the glasses should then be taken away, and manage the plants as above.

The tender kinds are propagated by seeds procured from abroad, sowing them in pots of light sandy earth, and plunged in the bark-bed; and when the plants are three inches high, plant them in separate pots, and plunged also in the bark bed, giving water and occasional shade till rooted.

These sorts must always remain in the hot-house, and have frequent moderate waterings.

LOCULAMENTA, *Loculi*, Cells, or Pockets, the internal divisions, or departments of a capsule or other dry seed-vessel.

These *Loculi*, or Cells, are those departments of a seed-vessel which immediately contain and inclose the seeds; and in point of number, some capsules have but only one Cell, others two, three, or many; when of one Cell it is termed *unilocular*; when of two, *bilocular*; of three, *trilocular*; of four, *quadriocular*; of five, *quinquelocular*; of ten *decemlocular*; of many, *multilocular*, &c. each Cell having, some but one, others several seeds; it being various in different genera.

LONICERA Honeyfuckle.

This genus retains a grand collection of celebrated deciduous flowering shrubs and some ever-greens, proper for all ornamental plantations, consisting both of upright growers, and twining climbers, rising from three or four to ten or twelve feet high; adorned with oblong, oval, and cordated mostly opposite

leaves, and a great profusion of elegant monopetalous, tubular, five-parted, very fragrant flowers, most part of summer.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, is small, five-parted, and rests on the germen. COROLLA, is monopetalous and tuberos, having an oblong gibbous tube, divided above into five reflexed segments. STAMINA, five subulate filaments, and oblong antheræ. PISTILLUM, a roundish germen under the receptacle, filiforme style, and obtuse capitated stigma. PERICARPIUM, an umbellicated bilocular berry, containing roundish compressed seed.

In this genus are now comprehended as species, several genera of former botanists, such as the *Diervilla*, *Symphoricarpos*, or St. Peter's-wort, *Periclymenum*, &c. Linnæus discovering their flowers to possess equally the same *Characters* as *Lonicera*, has retained them all as species only of this genus.

They may be divided into two classes, the upright growers, and trailers.

Upright Kinds.

These sorts rise with upright firm stalks, branching moderately, their branches mostly supporting themselves tolerably erect, forming low, upright, bushy heads; they are all hardy, deciduous, and most of them produce ornamental flowers, which however, are rather inferior both in numbers, beauty, and fragrance, to those of the trailing kind, but they nevertheless exhibit a pleasing elegance, and agreeable variety, in their general appearance; and are very proper furniture for the shrubbery.

The species of the above kinds commonly retained in our gardens are:

LONICERA *Alpigena*.

Alpine Upright Red-berried Honeyfuckle.] Rises with a shrubby, short, thick, upright stem, branching strong and erectly, four or five feet high; largish spear-shaped leaves, in pairs opposite; and from the sides of the branches many red flowers, by twos on long footstalks; each succeeded by two red berries joined together at their base; flowers in April and May, and the berries ripen in autumn.

²LONICERA *Cærulea*.

Blue-berried Upright Honeyfuckle.] Rises with a shrubby upright stem, branching moderately three or four feet high, the branches covered

covered with a purplish bark; oblong-lanceolate leaves, by pairs opposite; and from the sides of the branches, many white flowers by twos on short foot-stalks, each succeeded by a pair of blue berries joined together at the base: flowers in May, and the berries ripen in August.

³LONICERA *Nigra*.

Black-berried Upright Honeysuckle.] Rises with a shrubby upright stem, branching three or four feet high; oblong, elliptical, entire leaves; and white flowers, succeeded by black berries, single and distinct; flowering in May.

⁴LONICERA *Xylosteum*.

Xylosteum, or Fly Honeysuckle.] Rises a shrubby, strong, upright stem, branching seven or eight feet high, the branches having a whitish bark; oblong-oval, downy leaves, in pairs opposite; and from each side of the branches, erect white flowers, each succeeded by large double red berries, joined together at their base; flowers in June, and the berries ripen in September.

⁵LONICERA *Tartarica*.

Tartarean Honeysuckle.] Rises with a shrubby upright stem, branching erectly three or four feet high; heart-shaped opposite leaves; and whitish erect flowers, succeeded by red berries, sometimes distinct and sometimes double.

⁶LONICERA *Diervilla*.

Diervilla, or Yellow-flowered Acadian Honeysuckle.] Rises with shrubby upright stalks, branching erect, but moderately, three or four feet high; oblong, heart-shaped, pointed, serrated leaves, by pairs opposite; the branches terminated by racemus clusters of pale yellow flowers; flowers in May and June, continuing sometimes till autumn, but rarely ripens seed here.

⁷LONICERA *Symphoricarpos*.

Symphoricarpos, or Shrubby St. Peter's Wort.] Rises with a shrubby rough stem, branching erect four or five feet high, the branches slender and numerous; closely garnished with small oval opposite leaves on short foot-stalks; and small greenish flowers round the sides of the stalk; appearing in August.

Trailing, or Climbing Kinds.

These sorts have mostly weak declinated stalks and branches, which, unless supported, trail along the ground, some sorts rambling to a great length; but having support of stakes, or stems of trees, &c. they will climb or twine

round them many feet high, and often climb over the adjacent shrubs, hedges, or other support in their neighbourhood, for they are all volubilate climbers, ascending by twining spirally round any support, generally to the left, according to the apparent motion of the sun; they also, if trained against arbours, seats, walls, pales, &c. may be extended a considerable length, in the space of one summer; some of the sorts may also with a little trouble be trained as standards, as hereafter directed.

They are mostly of the deciduous tribe, except one species, and one or two varieties, which are ever-green: several of the sorts are remarkable for having the upper leaves sitting close, uniting at their base, so as to appear perforated by the stalk or branch; and all the sorts are remarkably floriferous; the flowers elegant and fragrant, generally continuing a month or two in succession, and the ever-green kinds much longer.

The most material species of the above kinds are:

⁸LONICERA *Periclymenum*.

Periclymenum, or Common Climbing Honeysuckle.] Comprehends two principal varieties; English wild honeysuckle—Dutch honeysuckle, &c. each of which furnishing also some varieties.

English Wild Honeysuckle, or Woodbine of our Woods and Hedges.] Rises with shrubby, weak, very long, slender stalks and branches trailing on the ground, or climbing round any support, and extend many feet in length; oblong-oval opposite leaves, distinct on short foot-stalks; and all the branches terminated by oval imbricated heads, furnishing smallish flowers of different colours in the varieties; flowering from June or July until autumn.

Varieties of this] With white flowers—with red flowers—with striped leaves—oak-leaved, having the leaves sinuated, or cut on the edges like those of the oak-tree—striped oak-leaved.

This species grows wild in England in great plenty in woods and hedges, and produce abundance of flowers, which however are small, but by garden-culture they are much improved: the plant and all its above varieties have generally very weak trailing stalks and branches, that they cannot be trained with upright stems, and their flowers are generally small; a few plants of each, however, are proper to introduce as climbers, to encrease the variety among the others.

The

The following varieties grow much stronger, and produce large and more elegant flowers.

Dutch, or German Honeyfuckle.] Rises with a shrubby declinated stalk; and strong-shooting, long, trailing, purplish branches, advancing a considerable length; oblong-oval opposite leaves, distinct, on short foot-stalks; and all the branches terminated by oval imbricated heads, furnishing large beautiful red flowers, of fragrant odour; appearing in June and July.

Varieties of this] Long-blowing, red, German honeyfuckle—late red-flowering—ever green late red-flowering, retaining its leaves all the year, and often its bloom till near Christmas.

⁹*LONICERA Caprifolium.*

Caprifolium, commonly called Italian Honeyfuckle.] Rises with shrubby declinated stalks, sending out long, slender, trailing, twining, greenish branches; oval, close-fitting, leaves, by pairs opposite, the upper ones closely join at their base, appearing perforated by the branch; and all the branches terminated by verticillate or whorled bunches of close-fitting flowers of great fragrance, of different colours and time of flowering in the varieties.

Varieties of this] Early white-flowering, appearing in May—early red-flowering; appearing also in May—late red-flowering, appearing in June and July, and is a fine sort—yellow-flowered—ever-green red-flowering, the leaves large, thick, and remain all the year; and it flowers from June until the end of autumn.

This species and varieties are easily distinguished, by producing their flowers in whorled bunches, appearing as if three or four bunches grew out of one another; are large, numerous, and sweetly scented.

The following is also valuable for its large elegant flowers, but are almost devoid of scent.

¹⁰*LONICERA Sempervirens.*

Ever-green Trumpet-flowered Honeyfuckle.] Rises with a shrubby declinated stalk, sending out slender, long, trailing, reddish branches; oblong-oval, close-fitting, shining, ever-green leaves, in pairs opposite, the upper ones closely join at the base, appearing perforated by the shoot, and all the branches terminated by naked verticillate spikes of long unreflexed, deep-scarlet flowers, of great beauty, but little fragrance.

This species and following varieties of it are also distinguishable by their flowers growing in whorled spikes.

Varieties of this] Large Virginia trumpet-honeyfuckle, having large bright-scarlet flowers—minor Carolina trumpet-honeyfuckle, with smaller scarlet flowers.

These are all the principal sorts of *Lonicera* that merit culture in our gardens, and that are to be met with in the nurseries for sale.

The flowers of all the ten species and respective varieties, are of one single, oblong, tubulous petal, it having the lower part a long tube, enlarging at top, and deeply divided into five, mostly reflexed segments, (see the *Characters*) and those of most of the sorts are ornamental, but preference is due to those of the trailing kinds, and which possess also the greatest fragrance.

The plants of all the sorts are shrubby, durable in root, stem, and branches; and so hardy as to grow in any common soil and situation, both in open exposures, and under shades of trees, more particularly the trailing kinds.

They are all admirable furniture for ornamental plantations in gardens, both for the variety of their different growths, and ornament and fragrance of their flowers; though the flowers of the upright kinds are not so showy as those of the trailers; but they, however, exhibit an exceedingly agreeable variety. Those of the trailing species have certainly the greatest merit both in their numbers, size, elegance, and odour, as well as in duration: however, the shrubs of all the sorts are proper to be introduced as plants of ornament in every shrubbery; the upright kinds to intermix as standard shrubs, they having upright firm stems, and erect moderate-shooting branches, forming handsome heads; but the trailing kinds, whose branches are great ramblers, and without support, trail along the ground, should generally be introduced as climbers, having stout stakes placed to each for them to climb upon, which they effect by ascending spirally round the support, to a considerable height; and may also be placed to ascend round the stems of trees, and to climb among the boughs of the adjacent bushes, shrubs, and hedges, which they will effect in a very agreeable manner, by interweaving their branches therewith, mount aloft, spread about, and show their flowers at top, appearing as if produced from the plant upon which they climb. In this manner may all the sorts of *Lonicera*, both upright growers, and climbers, be made to ornament our gardens.

I should

I should advise to disperse plenty of the different trailing *Loniceras* near the sides of all the principal walks, both for the beauty of their flowers, and for the delightful odour they constantly emit all around.

These climbers are likewise proper for training against walls, &c. for the ornament and fragrance of their flowers, training their branches four or five inches asunder; observing to thin out the superabundant shoots annually, and train in some of the most robust for succession wood, either at full length, or shortened as it may seem proper for the space designed to fill.

Having observed above, that the trailing kinds are principally adapted for climbers, I would however remark, that with a little pains they may also be made to form low bushy standards; this is done by training them at first to one upright stem, by means of stakes, and prune their rambling young shoots every year, as short as you shall see occasion, so as to keep them within proper bounds; by this practice they may be made to form tolerable standard shrubs, with erect firm stems, and bushy heads.

The ever-green kinds of these shrubs are principally all of the trailing tribe, and have singular merit, not only in their ever-green foliage, plentitude, and elegance of their flowers, but in their long continuance in bloom, which is frequently from June till November, and sometimes till Christmas, and after, in mild seasons; and those of the *Lonicera Caprifolium*, or Italian kind, impart a most agreeable fragrance: all of which kinds having long trailing twining branches, will form beautiful climbers; they may also be trained as standards by the means of supporting their stems at first, and stopping their young shoots as hinted above; but the Italian sort being the strongest shooter is the best for this purpose.

As to the general culture of all the sorts, they require very little; the upright sorts in particular, require to have only their straggling shoots shortened, and dead wood cut out; and the trailing kinds, which are trained as climbers, must have their branches conducted in a proper manner upon their respective supports; and every year all rambling shoots must be reduced and trained as you shall see proper, so as to preserve them within due limits, except you design they shall run wild in their own rural way, especially those intended to climb among the branches

of trees, shrubs, and bushes; those also intended to cover arbours and seats, should be pruned and trained annually, laying the shoots along at their length, especially till they have covered the allotted space; shortening or clearing out, however, all such stragglers which cannot be properly trained; likewise such of those sorts as are trained against walls, &c. must have an annual pruning and training, by going over them two or three times in summer, laying in some of the most convenient proper shoots, some at their length, shortening or retrenching others as it shall seem necessary to preserve regularity, and the proper succession of flowers; observing, however, to train enough, at this time, of such particularly as shall appear necessary to continue the bloom as long as possible; and in winter-pruning, thin out all those left in summer, which may now appear superfluous or unnecessary, and shorten all such as are too long for the space allotted for them, especially all those with weak straggling tops; and nail in the remaining proper branches and shoots close to the wall.

Propagation of all the Sorts.

The propagation of all the sorts is effected by layers and cuttings, more particularly the latter; both of which readily emits roots and form plants in one year, fit to transplant; some sorts are also propagated by suckers, and by seed.

By Layers.—In autumn, winter, or spring, lay a quantity of the lower young shoots of the former summer, by simple laying, shortening their straggling tops, they will be well rooted by autumn following, each commencing a good plant, and should be taken off and planted in nursery rows for a year or two, to acquire proper size and strength for use.

By Cuttings.—Any time from October till March is the proper time for this work, but the sooner the better; and by which method prodigious quantities of the plants may be raised, as almost every cutting will readily grow. Chuse the young shoots of the former summer, the strongest and most robust, and which divide into cuttings from about six or eight to ten or fifteen inches long, plant them in rows in any shady border of common earth, a foot asunder, and half that distance in each row, or closer if great quantities are required, putting each cutting two parts out of three, or more, into the ground; they will take root freely

freely without any trouble, and shoot at top, so as to form proper plants by autumn or winter following, at which time they may be transplanted into the nursery quarters, to have more room to grow, placing them in rows two feet distance, and a foot apart in the rows; where let them remain a year or two, or till wanted for the shrubbery.

By Suckers.—The *Lonicera Diervilla* sends up annually abundance of spawn, or small suckers from the root, by which it may also be propagated, each of which taken up in autumn or winter, and planted in the nursery will form a proper plant; observing this sort is likewise propagated with great ease by layers and cuttings as above.

By seed.—Several of the upright sorts, and others, furnish plenty of seeds, which if sowed in autumn, in a bed of common mould, an inch deep, many of the plants will probably rise in spring, but a great part of them are apt to remain till the second spring before they appear.

LOTUS, Bird's-foot Trefoil.

It consists of herbaceous and undershrubby plants for the pleasure-garden and green-house, some trailers, and some of erect growth, from one to two or three feet high, adorned mostly with trifoliate leaves, and papilionaceous ornamental flowers.

Class and order, *Diadelphia Decandria*.

Characters.] CALIX, is monophyllous, five-parted at top, and permanent. COROLLA, is papilionaceous, the standard roundish and reflexed backward, the wings shorter, broad and roundish, and the keel short and closed above. STAMINA, ten diadelphous filaments, and small antheræ. PISTILLUM, an oblong taper germen, a simple style, and inflexed stigma. PERICARPIUM, a close, cylindrical, bivalvular, unilocular pod, having numerous partitions separating the seeds.

The name Bird's-foot Trefoil given to the plants of this genus, is derived from the fancied resemblance of the bended seed-pods of some of the sorts, to the toes of birds feet.

There are many species, but those common to our gardens are, a hardy herbaceous annual for the pleasure-garden, and four undershrubby perennials for the green-house.

Hardy Annual Kind.

¹LOTUS *Tetragonolobus*.

Tetragonous Winged-podded Lotus, commonly called *Winged Pea*.] Hath trailing, slender, branchy stalks, a foot long; garnished with

trifoliate oval leaves, accompanied by two oval bractea at their base; and from the axillas of the branches large papilionaceous red flowers, one on each foot-stalk; succeeded by tetragonous solitary pods, having a membranous wing, or lobe, running longitudinally at each corner.

It flowers ornamentally in June and July, and the seeds ripen in autumn.

This plant is of the tribe of hardy annuals, and has been long cultivated as a flowery plant to adorn the flower-borders, &c. is generally sowed in patches where the plants are to remain.

Tender Green-house Kinds.

These kinds are perennial in root, and mostly with durable stalks; are natives of distant warm countries, and require protection here from frost, so must be kept in pots, and placed among the green-house plants.

The sorts are;

²LOTUS *Creticus*.

Cretan Silvery Lotus.] Hath a slender undershrubby stalk, rising by support three or four feet high; ornamented with trifoliate bright-silvery leaves; and from the sides of the branches long foot-stalks, each terminated by several yellow flowers, succeeded by subternate pods.

³LOTUS *Jacobæus*.

Jacobæus Lotus of St. James's Island.] Hath upright herbaceous stalks, branching two or three feet high; adorned with narrow, spear-shaped, close-fitting, whitish leaves, sometimes are trifoliate, and quinquefoliate; and from the upper part of the branches long slender foot-stalks, terminated each by three or five yellowish purple flowers, succeeded by subternate pods.

It flowers most part of summer and autumn, succeeded by plenty of seeds.

⁴LOTUS *Hirsutus*.

Hairy Italian Lotus.] Hath upright hairy stalks, branching a yard high; garnished with trifoliate hoary leaves; and from the sides of the branches longish foot stalks, terminated by heads of whitish hoary-cupped flowers; succeeded by oval pods; flowers in June, and the seeds ripen in autumn.

⁵LOTUS *Dorycnium*.

Dorycnium, or White Austrian Lotus.] Hath undershrubby smooth stalks, branching three or four feet high; five-lobed, hand-shaped, hoary leaves; and the branches terminated

minated by aphyllous heads of small white flowers; succeeded by short pods; flowers in June.

The flowers of all these species of Lotus are of the papilionaceous, or butterfly-shaped kind, composed each of four petals, i. e. a vexillum, two wings, and a carina. See the *Characters*.

The first species being a hardy annual of the flowery kind, is proper for ornamenting the compartments of the pleasure-garden. It is raised from seed annually in spring, in the open ground, in the places where the plants are to remain to flower. Sow it any time in spring, from February till May, in patches in different parts of the garden, five or six seeds in each patch, half an inch deep; the plants will soon come up, which remaining in the same place for flowering, require only occasional weeding, and may either be suffered to trail, according to their natural growth, or may tie them up to sticks; they will flower equally well in either method, exhibiting their crimson flowers very ornamentally.

This plant was formerly cultivated as an esculent, for its young green seed-pods to dress and eat like peas, also in the manner of kidney-beans.

The green house kinds effect an agreeable variety in that collection, both in their foliage and flowers. They all require shelter from frost, the two first of them in particular; but the two last are somewhat hardier, and will sometimes succeed in the full ground all the year in a warm and dry situation, so may place some to take their chance; it, however, is proper to keep some of all the sorts in pots of rich earth, in order for moving to shelter in winter.

The propagation of these green-house sorts is by seed, and by cuttings.

By Seed.—Sow it in April in a warm border; or, to bring them more forward, in a moderate hot-bed; and when the plants are about three inches high, plant them in separate small pots of light rich earth, give water, and place them in the shade till fresh-rooted.

By Cuttings.—Cuttings of the young stalks and branches, planted any time from April till July, in beds or pots of rich mould, giving shade and water, they will emit roots, and form plants in a few weeks, but may be greatly facilitated by covering them close with hand-glasses till they begin to shoot at top,

then inure them gradually to the air, and soon after may be transplanted into separate pots.

LUNARIA, Moonwort, Sattin-flower, or Honesty.

The plants are tall, herbaceous, ornamental annuals and perennials, of upright branchy growth, for the pleasure-garden, rising two or three feet high, garnished with heart-shaped, and oval-lanceolate leaves, and clusters and spikes of tetrapetalous cruciforme flowers; succeeded by broad, roundish, moon-shaped, flat, very thin pods, of a sattin colour, so transparent as to discover the seed through them; hence it is commonly called Honesty.

Class and order, *Tetradynamia Siliculosa*. *Characters*.] CALIX, four oblong-oval deciduous leaves. COROLLA, four large, obtuse, cruciforme petals. STAMINA, four long and two shorter filaments, and erect, patent antheræ. PISTILLUM, a pedicellated oval-oblong germen, very short style, and an obtuse entire stigma. PERICARPIUM, a large elliptical plane, compressed, very thin, bilocular pod, erected on a small foot-stalk, containing kidney-shaped, compressed, bordered seeds.

There are but two species, an annual and perennial, the former of which has been long a resident of our gardens, commonly known by the name of Honesty.

The species are:

LUNARIA Annua.

Annual Lunaria, commonly called Sattin-flower, or Honesty.] Hath fibrey roots, crowned by large heart shaped leaves; amidst them an upright reddish flower-stalk, branching all around, a yard high, adorned with heart-shaped leaves, opposite below and sitting close above; and from the sides and ends of all the branches clusters of cruciforme purple flowers, succeeded by numerous, broad, moon-shaped, white, fattiny, pellucid pods.

Variety.] Large podded sattin-flower, or honesty.

Both the varieties flower in May or June, and their pods and seed ripen in autumn; the seed-pods being numerous, white sattin-like, and transparent, exhibit a singularly agreeable appearance; and as they remain long on the branches, the stalks are often cut off in September, and dried, then tied in spreading bunches, to place in large rooms all winter, where they will appear very ornamental, more especially if the pods are divested of their

their outer husks, they will be whiter, more fatty and shining.

²*LUNARIA Rediviva.*

Redivive Sweet-scented Moon-wort.] Hath fibrated perennial roots; upright, firm, tough stalks, branching two feet high; garnished with oval-spear-shaped, rough leaves, placed alternate above; and the branches terminated by spikes of sweet-scented flowers, of different colours in the varieties; succeeded by oblong flat pods.

Varieties.] With purple flowers—with white flowers—and with yellow flowers; all flowering in June, succeeded by pods and ripe seeds in autumn, having the same property as the former.

The flowers of both the species, and respective varieties are cruciforme, and consist each of four heart-shaped petals, are numerous on each plant and conspicuous.

Both the species and their varieties are very hardy, and will grow any where; the first sort decays annually after having flowered and seeded; but the perennial is of several years duration in root, especially if cultivated in a dry sandy, or rubbishy soil.

The first species, *Lunaria Annua*, however, may be considered both as an annual and biennial; for, as an annual, being sowed early in spring, it will come up the same season, and often run up to flower, perfect seeds, and wholly perish in autumn; and as a biennial, if sowed in summer, or early in autumn, it will rise the same year, stand the winter, flower early in summer, perfect seeds in autumn, and then totally perish; for considered either as annual or biennial, it always decays root and branch soon after the seeds are ripe; remarking that the autumn-sowed plants always grow strongest, and from scattered or self-sown seeds, numbers of young plants will rise spontaneously.

But as to the second sort, it being once raised, it remains perennial in root, sending up fresh stalks annually in spring for flowering, which always decay as soon as they have perfected seeds.

The propagation of both the species, &c. is by seed, in the natural ground in autumn or spring, either in patches to remain, or in beds for transplantation. By the former method the plants are generally stronger than those which are transplanted; but they succeed very well both ways; observing, when designed to sow them in patches, to put several seeds in each, half an inch deep, and

when the plants come up, leave only one of the best in each patch; and if intended to sow any for transplantation, sow them evenly on any bed or border, and rake them in; and when the plants are two or three inches high plant them out, the annual sorts where they are finally to remain to flower; and the perennials either where they are to remain, or in nursery beds till autumn, then to be planted out for good.

LUPINUS, Lupine.

This genus consists of hardy, herbaceous, flowery annuals, and a perennial, all for the pleasure-garden, rising with upright stalks, from about a foot to three or four high; ornamented with digitate, or fingered leaves, and terminated by long whorled spikes of papilionaceous flowers.

Class and order, *Diadelphia Decandria.*

Characters.] CALIX, is monophyllous and bifid. COROLLA, is papilionaceous, the vexillum roundish-cordate, emarginate, with the sides reflexed and compressed, the wings nearly oval, and join at their base, and a narrow, falcate, acuminate carina. STAMINA, ten diadelphous filaments, and roundish-oblong antheræ. PISTILLUM, an awl-shaped compressed germen, subulated style, and obtuse stigma. PERICARPIUM, a large oblong, compressed; acuminate, coriaceous, unilocular pod, containing several roundish compressed seeds.

There are about seven species, six annuals and one perennial, all hardy, and mostly plants of ornament, both in their finely digitate leaves, and variety of their flowers.

Annual Kinds.

Of these kinds there are about four or five species common to our gardens; have all fibrated roots, each plant rising with one upright branchy stalk, as in their description.

LUPINUS *Lutea.*

Yellow Lupine.] Rises with an upright stalk, branching a foot or eighteen inches high; garnished with digitate leaves, of eight or nine long narrow lobes; and the stalks and branches terminated by loose whorled spikes of yellow flowers, having verticillate cups with appendages, the upper lip bipartite, and the under one tridentate; flowers in June and July.

The flowers of this have a sweet fragrance, for which peculiar merit it is in great estimation.

²LUPINUS *Hirsutus*.

Hairy Giant Lupine.] Rises with an upright, thick, downy, hairy stalk; branching strongly three or four feet high; garnished with digitate hairy leaves, of from nine to eleven, oblong, wedge-shaped, silvery-white lobes; and the stalk and branches terminated by long whorled spikes of large flowers, of different colours in the varieties, having alternate cups with appendages, the upper-lip bipartite, the under one tridentate.

Varieties.] With blue flowers—with flesh-coloured flowers, commonly called Rose Lupine. The flowers of both varieties are large and showy, appear in July, and are succeeded by large, broad, hoary seed-pods.

³LUPINUS *Angustifolia*.

Narrow-leaved Tall Blue Lupine.] Rises with an upright firm stalk, branching a yard high; digitate large leaves, of nine or ten oblong, obtuse, blueish lobes; and the stalks and branches terminated by whorled spikes of blue flowers, having alternate cups with appendages, the upper-lip bipartite, and the under entire; flowers in July.

⁴LUPINUS *Varius*.

Variegated-seeded Blue Lupine.] Rises with an upright firm stalk, two feet and a half high; digitate leaves, of six or seven oblong hairy lobes, and the stalk and branches terminated by spikes of blue flowers, having semi-verticillate cups with appendages, the upper-lip bifid, and the under almost tridentate; and with variegated seed.

⁵LUPINUS *Alba*.

White Lupine.] Rises with an upright thick stalk, branching two feet high; digitate leaves of seven or eight narrow hairy lobes, covered with a silvery down; and the branches ending in loose spikes of white flowers, having alternate cups without appendages, the upper lip entire, and the under tridentate.

All these annual Lupines rise from seed sowed annually in spring and summer in the open ground, arrive to full growth in June and July, when they flower, and ripen seed abundantly in autumn, then the plants totally perish root and branch.

They are all very ornamental in the pleasure-garden, but the yellow sort claim precedence for the sweetness of its flower.

Perennial Kind.

There is but one sort, it is perennial in root, and annual in stalk.

⁶LUPINUS *Perennis*.

Perennial Blue Virginia Lupine.] Hath long fibrated, creeping, deeply-penetrating roots; upright channelled stalks, branching near two feet high; digitate leaves of eight or ten spear-shaped narrow lobes; and the branches terminated by loose spikes of blue flowers, having alternate cups, without appendages, the upper-lip emarginated, and the under one entire; flowers in June.

All the species flower in June and July, and ripen plenty of seeds in autumn.

The flowers of all the sorts are papilionaceous, consisting of four petals, that is, a standard, two wings, and carina (see the *Characters*), and grow in erect spikes, often disposed in whorls one above another; which in all the sorts, are succeeded by oblong compressed, leguminous pods, containing from three to five or six roundish flat seeds.

The leaves of all these plants are beautifully digitated into many lobes, stand mostly upon long foot-stalks, and exhibit an agreeable variety.

The plants of all the sorts succeed in any of the open borders, &c. and effect a fine variety, as well as very ornamental appearance; and are all easily raised from seed, which should generally be disposed in small patches in the different flower compartments, in the places where it is designed the plants shall flower; placing some more forward, and others backward, according to their order of growth; observing the annuals must be raised annually, as they always perish soon after they have flowered and ripened seeds; but the perennial sort, once raised is of several years duration.

Propagation, &c. of all the Sorts.

The propagation of all the sorts is effected with the utmost facility by seed in the full ground in March, April, and May; observing, that as too copious moisture is apt to rot the seed, they should not be sowed earlier than the middle or latter end of March, except on very dry warm soils.

The annual sorts should always be sowed at once in the places where it is intended the plants are to flower, for they do not succeed by transplantation; and to have a long succession of bloom, about three or four different sowings may be necessary, from about the middle or latter end of March until June, especially the yellow sort, whose bloom is rather of short duration; observing to sow all the

the sorts in patches, four, five, or six seeds in each, near an inch deep; and when the plants come up, leave only three of the best of them, though of the large kind one or two may be sufficient in each place. When large quantities are required for nosegays, to supply the markets, &c. as practised about London with the yellow sweet-scented sort, they may be sowed in rows in beds, drilling them in an inch deep, allowing a foot between the rows. In either mode of sowing all the sorts, let the plants remain in the same place for flowering, as above mentioned, and keep them clean from weeds, which is all the culture they require; and by repeated sowings at a month's interval, the bloom may be continued from June or July until September or October; and the first sown plants will furnish plenty of ripe seed.

If some seeds are sowed in autumn, in September, in a warm dry situation, the plants will come up, and often stand the winter tolerably well, and flower early the following year; or, if some are sowed in pots, especially the giant sort, comprising the large blue, and the rose Lupine, which in wet autumns ripen seed but indifferently; so that by placing the pots in a garden frame, to have occasional protection from hard frost, they will flower early in the following summer, so as to perfect seeds before they are attacked by the autumnal rains.

The perennial sort may be sowed either in patches in the different compartments, as already observed, for the plants to remain where sowed; or may be sowed in beds in drills, for transplantation; but as the plants generally send their roots deep into the ground, they generally succeed best when permitted to remain where raised, than by removal; however, both methods may be practised occasionally, and the plants once raised remain durable in root many years, sending up new stalks annually in spring.

LYCHNIS, *Lychnis*, or *Campion*, including also the *Bachelors-button*, *Catch-fly*, &c.

It consists of hardy, herbaceous, very floriferous ornamental perennials, of upright growth for the pleasure-garden, rising with erect firm stalks, two or three feet high, adorned at each joint with long spear-pointed leaves; and all the stalks terminated by clusters and spikes of quinquepetalous, very conspicuous flowers, of different colours in different species.

Class and order, *Decandria Pentagynia*.

Characters.] CALIX, is monophyllous, tubulous, five-parted at top, and permanent. COROLLA, five petals, having long tails, or unguis, the upper part, or limb, broad plane, and in some cut into segments. STAMINA, ten long filaments, alternately arranged, and attached to the unguis of the petals, and incumbent antheræ. PISTILLUM, a suboval germen, five long styles, and reflexed downy stigma. PERICARPIUM, an oval, *unilocular*, quinquevalvular, covered capsule, having numerous roundish seeds.

There are about seven species, but not more than four that have merit as garden-plants, viz. the scarlet *Lychnis*—*Bachelors-button*—*Catch fly*—*Ragged Robbin*: each comprising some varieties.

The species are;

¹LYCHNIS *Chalcedonica*.

Chalcedonian Scarlet Lychnis.] Hath a fibrated perennial root; upright, straight, hairy, annual stalks, rising three or four feet high; garnished with long, spear-pointed, close-fitting leaves, by pairs opposite; and the stalk crowned by a large, compact, flat bunch of beautiful scarlet, or flame-coloured flowers; appearing in June and July.

Varieties.] With single scarlet flowers—with large, double, scarlet flowers, of exceeding beauty and elegance—with pale-red flowers—with white flowers.

Of these varieties of this species, the double scarlet *Lychnis* is superior to all for size and elegance, the flowers being large, very double, and collected into a very large bunch, and exhibit a charming appearance; the single scarlet kind is also very pretty; and the others effect an agreeable variety with the scarlet kinds. All the singles furnish plenty of seed, by which they may be raised abundantly; but the double, by its multiplicity of petals, exclude the generative organs, rarely ever produce seed, so can only be propagated by slipping the roots, and by cuttings of its flower-stalks. See the *Propagation*.

²LYCHNIS *Dioecia*.

Dioecious Lychnis, commonly called *Bachelors-button*.] Hath fibrated perennial roots; upright stalks, branching very diffuse and irregular, two or three feet high; having oval, acute-pointed, rough leaves, by pairs opposite; and all the branches terminated by clusters of dioecious flowers of different colours and properties in the varieties; flowering in April and May.

Varieties.] Common single red-flowered Bachelors-button—double red—double white—and single white-flowered.

The double varieties are exceedingly ornamental in their bloom; the flowers large, very double, and continue long in blow; the single red sort grows wild by ditch sides, and other moist places in many parts of England; from which the doubles were accidentally obtained by culture in gardens, and are propagated only by slipping the roots; and the singles, both by roots and by seed.

The flowers are often dioecious, i. e. male and female on distinct plants.

³LYCHNIS *Viscaria*.

Viscous, German Lychnis, commonly called Catch-fly.] Hath fibrey perennial roots; crowned by a tuft of long, grassy leaves close to the ground; many erect, straight, single stalks, rising a foot and a half or two feet high, exuding from their upper part a viscous or clammy matter; garnished with long narrow leaves, by pairs opposite; and terminated by many reddish-purple flowers, in clusters one above another, forming a sort of long loose spike; all the flowers with entire petals; flowering in May.

Varieties.] With single red flowers—with double red flowers—with white flowers.

The double variety is considerably the most eligible for general culture, and is propagated in plenty by parting the roots.

All the varieties of this species emitting a glutinous liquid matter from their stalks, and flies happening to light thereon, sometimes stick and entangle themselves, the plant thereby obtained the name Catch-fly.

⁴LYCHNIS *Flos-cuculi*.

Cuckoo-flower Lychnis, commonly called Ragged Robin.] Hath fibrey perennial roots; upright, branchless, channelled stalks, rising near two feet high; garnished with long, narrow, spear-shaped leaves, in pairs opposite; and terminated by branchy foot-stalks, sustaining many purple, deeply quadrifid flowers; appearing in May.

The flowers having each petal deeply quadrifid in a torn or ragged-like manner, the plant obtained the cant name of Ragged Robin.

Varieties.] With single flowers—double flowers. The double sort is a large, very multiple, fair flower, is an improved variety of the single, which grows wild in most of our moist meadows, and is rarely cultivated; but the double, being very ornamental, merits cul-

ture in every garden; it, like the other double Lychnises, rarely produces seed, but is easily propagated by slipping the roots.

All the four species and respective varieties are very hardy; all fibrous-rooted, the roots perennial; but are annual in stalk, which rises in spring, flower in summer, succeeded in the singles by plenty of seed in autumn; by which all the single varieties may be raised in abundance, but the doubles only by dividing the roots, and some by cuttings of the flower-stalks.

The flowers of all the sorts, considered separately, are smallish, but their numbers on each plant renders them conspicuous; each flower in its single state, is composed of five plane petals, (see the *Characters*); but in the doubles, the petals are numerous; the singles succeeded by plenty of seed, but the doubles rarely any.

All these plants are very ornamental furniture for the pleasure-garden, particularly the doubles, and will prosper in any common soil, will remain in all weathers unhurt, and each individual be of many years duration in root, which when of some standing, send up many stalks every spring, and which being all terminated by numerous flowers, make a fine appearance in summer; but the scarlet Lychnis claims preference, especially the double kind, which is singularly beautiful, even the single scarlet sort is also very showy and pretty, and by some preferred to the double; all the other species, however, in their respective double-flowered states, are pretty ornaments for the principal compartments of the pleasure-ground.

All the sorts are kept in the nurseries for sale; and having a few plants of each, may soon encrease the stock.

They may be planted any time from October till March in open weather, though if in autumn the better; observing to place the tallest growers the most backward, the others more toward the front, according to their several degrees of height.

All the culture they require, is the clearing them from weeds in summer, in common with the other plants of the same compartments; supporting with stakes the stalks of those which shall need it, and cutting down the decayed stalks in autumn.

Propagation of all the Sorts.

The propagation of all the sorts is exceeding easy; all the singles by seed, and parting the

the roots; and the doubles by dividing or slipping the roots only, sometimes also by cuttings of their stalks; all performed in the full ground.

By Seed.—The singles may be raised in great plenty this way, though but few of them except the single scarlet *Lychnis*, are worth raising, since the doubles may be so easily increased by slipping the roots, &c. March or April is the proper time for sowing, chusing a bed or border of light earth, which being dug, sow the seeds on the surface, each sort separate, and rake them in; the plants will come up in two or three weeks, give occasional waterings and hand-weeding; and in June, when the plants are two or three inches high, plant them out in beds or borders, in rows six inches asunder; water them till fresh-rooted, and let them remain till October, then transplant them where they are to remain, and they will all flower the following summer.

By Slipping the Roots.—All the sorts, both single and double, may be propagated by this method, but is more particularly applicable to the doubles, because they cannot with certainty be obtained from seed; the best season for performing this work is autumn, after the stalks decay; it, however, may also be done in the spring: the scarlet *Lychnis* affords off-sets the most sparing of any; all the others afford plenty; as to the method of slipping them, the whole root may either be taken up and divided into as many slips as are furnished with proper root-fibres, or the main root may stand, and slip off as many of the outer off-sets as shall seem convenient; if the slips taken off in either method are tolerably strong, the best of them may be planted at once where they are to remain; but if rather small and weak, it is the most eligible to plant them in nursery-rows, half a foot asunder, to remain a year, then transplant for good.

By Cuttings of the Stalks.—This is more particularly necessary for the double scarlet *Lychnis*, when it increases but sparingly by off-sets of the root. The work is performed in summer, when the stalks are well advanced in growth, but before they flower, or have become hard and woody: cut some of them off close to the bottom, and divide them into lengths of from three to five joints, and plant them in an easterly border of rich earth, putting them two parts of three, or more, into the ground, leaving only one joint out; give water directly, and repeat it, together with

occasional shade in hot weather, and they will be well rooted, and form proper plants fit to transplant in autumn.

If the above cuttings, as soon as planted, are covered down close with hand-glasses, it will greatly promote their rooting, so as to form stronger plants before winter.

LYCIUM, Box-thorn.

This genus retains three shrubby exotics of Africa, &c. for the green-house and shrubbery, rising from about six or eight to ten feet high, armed with spines, and adorned with small entire leaves, and monopetalous infundibuliforme flowers.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, is small, obtuse, erect, five-parted, and permanent. COROLLA, one funnel shaped petal, having a cylindric incurved tube, divided above into five small segments. STAMINA, five short subulated filaments, and erect antheræ. PISTILLUM, a roundish germen, simple style longer than the stamina, and thick bifid stigma. PERICARPIUM, a roundish bilocular berry, and numerous reniforme seeds.

The species known in our gardens are;

LYCIUM Afrum.

African Narrow-leaved Box-thorn.] Hath shrubby irregular stalks, branching nine or ten feet high, the branches whitish, crooked, knotty, and armed with long sharp spines; numerous small linear leaves in clusters, of different sizes in each cluster, the smaller standing at the base of the larger; and purple flowers on short foot-stalks from the sides of the branches.

²LYCIUM Barbarum.

Barbary Rosemarinus-leaved Lycium.] Hath shrubby stalks, branching irregularly six or seven feet high, the branches whitish, and armed with thorns; small spear-shaped, oval, thick, whitish leaves, placed irregularly; and small white flowers from the sides of the branches, having bifid cups; flowers in June.

Of this species are the two following varieties, both shrubby trailers, of hardy temperature; they were formerly considered as distinct species, but observation has determined them to be varieties only of the above species, *Lycium Barbarum*:

Trailing Broad-leaved Barbary Lycium.]

Hath shrubby, declinated, very diffused stalks and branches of trailing growth, advancing irregularly many feet in length, spread about every way, and armed with very long thorns; large

large, oval, spear-shaped, thick, whitish-green leaves, growing on all sides by threes; and purplish flowers, singly on short foot-stalks from the sides of the branches, having bifid cups; flowering from August till October.

Trailing Narrow-leaved Barbary Lycium.]

Hath shrubby, very branchy stalks, of trailing growth, spreading irregularly every way, armed with short thorns; long, lanceolate, narrow, alternate, whitish-green leaves; and small flowers, having bifid cups; flowering in June and July.

The flowers of all the sorts consists of one funnel-shaped petal, with an incurved tube, divided above into five parts; see the *Characters*.

All the four sorts are durable in root, stem, and branches, and both the species are evergreen, retaining their leaves all the year; and they all flower here annually in summer.

The two species being somewhat tender require protection from frost, so must be kept principally in pots, and placed among the green-house plants, where, as being closely garnished with numerous small foliage, they will effect an eligible variety in that collection; some of them may also be placed in a warm part of the shrubbery to take their chance, and will succeed tolerably, except in very severe winters.

But the two varieties of the *Lycium Barbarum* are hardy, succeed in the open ground the year round, and are proper for the shrubbery, to introduce as trailers or climbers, for their branches trail and ramble about every way, so should have support of stakes, &c. to train them upon.

They all succeed in any common earth of a garden; let the green house sorts, however, be potted in light, rich, loamy mould, if possible.

Propagation.

The propagation of all the sorts is by seed, layers, and cuttings; but as they all grow freely by the two latter methods, raising from seed is almost unnecessary, especially to the two hardy varieties.

By Seed.—This is sometimes practised for the green-house kinds; sow the seed in autumn in pots, an inch deep, which in winter place in a frame, &c. to have shelter from frost, but to enjoy the full air in open weather; and in spring plunge them in a mode-

rate hot-bed, it will soon bring up the plants; when they are about three inches high, plant them in separate pots, give water, and place them in the shade till fresh-rooted, and repeat the waterings as there shall be occasion.

By Layers.—In spring lay a quantity of the young branches, by simple or common laying, they will readily emit roots, and be proper for transplanting in autumn.

By Cuttings.—In March or April plant cuttings of the young shoots of the green-house kinds in pots, and plunge them in a shady border, give water in hot-weather, and they will readily grow; or if any time from April till the end of June, young cuttings are planted in a shady border, they will emit roots, and form plants fit to be potted in autumn; but cuttings of the two hardy varieties planted at almost any time of the year will readily grow, though from October till March is the best time, and they will form good plants by autumn following.

LYSIMACHIA, Loose-strife.

The plants are hardy herbaceous perennials and biennials, &c. of upright growth, mostly for the pleasure-garden, rising with erect stalks, from about half a yard to two or three feet high; garnished with narrow, entire leaves; and terminated by spikes and clusters of monopetalous, rotated, five-parted, spreading flowers.

Class and order, *Pentandria Monogynia*.

Characters.] *CALIX*, is erect, acutely five-parted, and permanent. *COROLLA*, is monopetalous, rotaceous, and deeply divided into five flat, open-spreading segments. *STAMINA*, five subulate filaments, and acuminate antheræ. *PISTILLUM*, a round germ, filiforme style, and obtuse stigma. *PERICARPIUM*, a globular, decemvalvular, unilocular capsule, having many angular seeds.

There are many species, but not more than three or four commonly retained in gardens, and those mostly perennials; all the sorts having fibrated roots, sending up stalks annually.

The species are;

LYSIMACHIA Vulgaris.

Common Great Yellow Loose-strife.] Hath a thick, creeping, widely-spreading, reddish root; upright firm stalks, three or four feet high; garnished with spear-shaped, pointed, sessile leaves, by threes or fours; and each stalk dividing at top into several foot-stalks, each

each of those terminated by a racemous cluster of elegant yellow flowers; in June and July.

This inhabits ditch-sides and moist places in many parts of England; but being a tall, fine showy plant in bloom, it is admitted into large gardens for the variety of its flowers.

²*LYSIMACHIA Ciliata.*

Ciliated Canadian Yellow Loose-strife.] Hath a creeping, fast-spreading root; many upright stalks, rising two feet high; oval-lanceolate, smooth, opposite leaves, having ciliated foot-stalks; and from the upper axillas, long slender foot-stalks, each sustaining one yellow flower; in June and July.

³*LYSIMACHIA Nummularia.*

Nummularia, commonly called Yellow Money-wort, or Herb Two-pence.] Hath a small, creeping, spreading root; numerous, weak, trailing, rooting stalks; small, nearly heart-shaped, smooth, opposite leaves; and from the axillas, long slender foot-stalks, each having a solitary yellow flower; in June and July.

It grows naturally in moist shady places in England, but is cultivated in many gardens for variety.

⁴*LYSIMACHIA Salicifolia, or Willow-leaved white Spanish Loose-strife,* is now removed to another genus; it grows three feet high, having spear-shaped, narrow leaves, and the stalks terminated by long loose spikes of fine white flowers; in June.

The flowers of all these plants are each of one rotaceous, or wheel-shaped, deeply-five-parted petal, are pretty numerous on each plant, tolerably conspicuous, and are succeeded by ripe seeds in autumn, except the ciliated kind, which rarely produce seeds in England.

All the plants are perennial in root, and annual in stalk, and all of them multiply exceedingly by their creeping roots.

They are all very hardy, prosper in any common soil and situation in a garden, but delight most in somewhat shady moist places; they, however, may be planted any where to form a variety, and their roots will abide for years, and encrease greatly so as to send up many stalks, and exhibit a very showy bloom.

All the sorts here specified are kept in most of the nursery gardens for sale.

They may be planted any time from October till March, and their culture is only the keeping them clear from weeds, and cutting

down their decayed stalks in autumn, like other herbaceous perennials; and when the roots have spread too much, trim them in all around within due bounds.

Propagation.

The propagation of all the sorts is effected abundantly by parting their roots any time, from the decay of the stalks in autumn until new ones begin to rise in spring.

They may also be propagated by seed; sowing them in autumn upon an east border, and the plants will rise plentifully in the following spring, some of which, when about three inches high, may be thinned out and planted in a shady border till autumn, when these, and all the others may be transplanted where they are to remain.

LYTHRUM, Willow-herb, (Salicaria) or Purple Loose-strife.

It furnishes some hardy herbaceous, erect-growing, flowery perennials for ornamenting the pleasure-garden compartments, rising with upright stalks, from one to three or four feet high; adorned with cordate-lanceolate, and linear leaves; and terminated by long spikes of hexapetalous, very ornamental, purple flowers.

Class and order, *Dodecandria Monogynia.*

Characters.] *CALIX*, is monophyllous cylindrical, having the brim indented in twelve parts alternately smaller. *COROLLA*, six oblong, obtuse, patent petals, inserted into the denticuli of the calix. *STAMINA*, twelve filaments, the upper ones the shortest, and assurgent antheræ. *PISTILLUM*, an oblong germen, subulate, declinated style, and rising orbicular stigma. *PERICARPIUM*, an oblong, acuminate, unilocular, covered capsule, inclosing numerous small seeds.

There are about nine or ten species, but not more than one in esteem for our purpose, or that is commonly cultivated in the English gardens, which, however, comprehends some varieties.

LYTHRUM Salicaria.

Salicaria, or Common Willow-herb.] Hath a fibrated perennial root; upright, angular, purplish stalks, rising three or four feet high; cordate-lanceolate leaves, opposite by pairs; and the stalk and branches terminated by long, erect spikes of reddish-purple, dodecandrous flowers; in July.

Varieties.] With round leaves—with long acute leaves—trifoliate leaved, growing three leaves

leaves at a joint—quadrifoliate; or four leaves at a joint—with quadrangular stalks—with hexangular stalks—with bright red flowers—purple-flowered—with verticillate, or whorled flowers.

This beautiful plant and varieties are residents of brook-sides, and the like places in most parts of England, and are often disregarded; they, however, merit culture in every curious garden for their stately growth and ornamental appearance of their elegant flowers, which adorn the top of the stalk in very long erect spikes.

They are all very hardy, perennial in root, and annual in stalk.

They may be employed to ornament any of the compartments of the pleasure-ground, but are the most prosperous in moist, or somewhat shady situation, in which they will grow taller, stronger, produce larger spikes, and continue longer in beauty.

The plants may be easily obtained in the places of their natural growth, and are sold at most of the nurseries; and the season for planting them is any time in open weather from October till March.

The propagation is by parting the roots, and by seed.

By parting the Roots.—Autumn, in October or November, is the best season: the root may be divided into slips, preserving fibres to each which if tolerable strong, plant them at once where they are to remain; but if weak, set them in nursery rows for a year.

By Seed—This is hardly worth practice, since the plants may be encreased with the utmost facility by roots; however the most successful sowing-season is autumn, soon after the seeds are ripe, sowing them in a bed or border of rich earth, and rake them in; they will rise in spring; in summer, if too thick, thin out some and plant them in nursery-rows till autumn; when both these, and those remaining in the seed bed may be planted out for good, and will flower the next summer.

LUXURIANS, Luxuriant Plants, &c.—These are such that are greatly augmented in growth beyond their common natural state; and it is observable of such plants, &c. for the general part, that they rarely acquire that degree of perfection as plants of more moderate growth; and which state of Luxuriance sometimes happens through the excess of nourishment, and sometimes by the nature of some particular plants.

But Luxuriance operates differently; it prevails sometimes in the whole plant, sometimes in particular parts of a plant, as in some of the shoots, and frequently in the flowers. We shall therefore consider them under these three heads: 1. Luxuriant Plants—2. Luxuriant Shoots—3. Luxuriant Flowers.

Luxuriant Plants and Trees.—These as above observed, are such as shoot considerably stronger than plants of the same species generally do, and is applicable both to herbaceous plants and trees, &c. and that very Luxuriant Plants and Trees never attain perfection so soon as moderate growers, as for example: most esculent plants which shoot luxuriantly to leaves and stalks, &c. such as cucumbers, melons, cabbage, cauliflowers, turneps, radishes, beans, peas, &c. never arrive so soon to perfection as those of moderate growth, and such plants as appear to be naturally of themselves of that very Luxuriant nature are very improper to stand from which to save seed for propagation.

The same is also observable of fruit-trees; for such as are very Luxuriant shooters are much longer before they attain a bearing state, than those of middling growth, nor do they ever bear so plentifully, nor the fruit attain such perfection as in moderate-shooting trees: this Luxuriance happens sometimes through excess of nourishment, as before observed, and sometimes is the nature of the tree, and very frequently is acquired by unskillful pruning, for it is very often the practice of bad pruners, that when wall or espalier trees assume a Luxuriant growth, to cut all the shoots short, by which practice, instead of reducing the tree to a moderate state of shooting, has increased its vigour, because, as we have before occasionally observed, the shortening of strong shoots, promotes their throwing out still stronger, and producing more abundant or superfluous wood.

Therefore, in pruning very Luxuriant espalier and wall-fruit-trees, assist them in their own way, by training in plenty of shoots annually for a year or two, to divide the redundancy of sap; that is, in training in the necessary supply of shoots, both in the summer and winter pruning, always leave them rather thicker than in the common practice, and mostly at full length, unless it shall seem necessary to shorten any in some particular part of the tree, to force out a supply of wood to fill a vacancy; observing that some sorts of fruit

fruit-trees should never be shortened, except occasionally for the purpose of procuring a supply of wood as just mentioned, which is particularly to be remarked in apples, pears, p'ums, cherries, figs, &c. for if shortening was to be practised to these sorts, they would continue shooting every year so luxuriantly to wood, that they would never form themselves into a proper bearing state: even those trees where shortening is necessarily practised in winter, to most of the annual supply of shoots, as in peaches, nectarines, &c. it, in cases of Luxuriant growth, should be very sparingly performed, that is, not to cut any of the shoots very short, and some of the most vigorous leave almost, or quite at full length.

This is the only method to reduce a Luxuriant tree to a moderate growth, and to a bearing state; for by training the shoots thicker, and leaving them longer, and continuing it for a year or two, the redundant sap consequently having greater scope to divide itself, it cannot break out with that Luxuriance, as when it has not half the quantity of wood to supply with nourishment, as in the case of pruning short; and by practising the above hints, a Luxuriant tree may in two years be brought to a moderate growth, and become a good bearer. See *ESPALIERS, WALL-TREES, PRUNING, &c.*

Luxuriance seldom occurs with any continuance in standard-trees where permitted to take their natural growth, except sometimes a straggling shoot, which should always be taken out by the rules mentioned in the following article.

²Luxuriant Shoots.—These are applicable principally to trees and shrubs; more particularly to the fruit-tree kind, and especially those which undergo the discipline of an annual pruning; Luxuriant shoots, therefore, are frequently mentioned in the culture of the several sorts of fruit-trees.

However, Luxuriant shoots are such which shoot so vigorously in length and substance, as greatly to exceed the general growth of those usually produced on the same kind of plant or tree, and are sometimes general, and sometimes only happens to particular shoots in different parts of a tree, &c. and those shoots denominated Luxuriant, are discoverable by their extraordinary length and thickness, and by their vigour of growth, which always greatly impoverishes the other more moderate shoots in their neighbourhood, and likewise the fruit, &c. and such shoots

very frequently occur in fruit-trees by the effects of pruning. When they are in general so, that is, all, or most of the shoots of an espalier or wall-tree are Luxuriant, manage them as above directed in treating of Luxuriant trees; but when luxuriance happens to particular shoots here and there in a fruit-tree, or indeed any other tree or shrub, under training, that such shoots being both of such a very Luxuriant nature as to draw the nourishment, or sap, at the expence of all the adjacent moderate shoots on the same tree, and often by its vigorous irregular growth, cannot be trained with any degree of regularity; so that considering these disadvantages of straggling Luxuriant shoots, they should for the most part, as soon as discoverable, in summer or winter pruning, be cut out, taking them off as close as possible to the part of the branch from whence they originate, that no eye may be left to shoot again; unless, however, such a shoot shall rise in any part of a tree or shrub, where a further supply of wood may be requisite, in which case it may be retained, and shortened as it shall seem convenient to force out a supply of more shoots laterally to fill the vacancy.

But, as above noticed, where a tree is wholly of a Luxuriant nature, producing almost in general Luxuriant shoots, leave them moderately thick, and train them along mostly at full length, and by thus leaving a larger supply of wood for the sap to divide itself, the tree in two seasons will be reduced to a proper growth; when it may afterwards be managed according to the general rules exhibited under its respective genera.

³Luxuriant Flowers.—All double flowers may be considered as Luxuriant, especially such which have either the cup or corolla multiplied, or so augmented in numbers inward, as to exclude some part of the fructification, for the same is observable in flowers as in esculent plants and fruit-trees, that Luxuriance tends to their imperfection in the original intention of nature; the flower being designed for perfecting the fruit and seed; but when the petals are multiplied to the diminution of the stamina, &c. so that no impregnation ensues, no fruit or seed can be produced, consequently, by the Luxuriant augmentation of the corolla, plants often become barren.

Luxuriance in flowers, however, consists of three modifications. First, such as have the petals multiplied, yet do not entirely

exclude the stamina. Secondly, such in which, by the multiplicity of the petals, all the stamina are excluded, so that no impregnation can be effected. Thirdly, such flowers as produce one out of another, as in the prolific anemone, &c.

But Luxuriant flowers which do not ex-

clude all their stamina, are capable of impregnation, and consequently produce seed.

The highest degree of luxuriance is often observable in carnations, anemones, ranunculus, poppy, lychnis, peony, narcissus, violet, &c.

M.

MAGNOLIA, (*Magnolia*) Laurel-leaved Tulip-tree.

This genus consists of most elegant ever-green and deciduous trees of North America, for ornamental plantations and the greenhouse; rising with upright trunks, dividing upward into fine regular heads; adorned with noble large, oblong, simple foliage, and large novem-petalous flowers of remarkable fragrance; which, in America, their native soil, are succeeded by a large egg-shaped strobilus, scaly fruit, composed of several compressed, roundish, unilocular capsules, containing large pendulous seeds, i. e. that being discharged from their departments, hang by long threads in a singularly curious manner; but the fruit never attains perfection in England, and is not of the eatable kind.

Class and order, *Polyandria Polygamia*.

Characters.] CALIX, is three petaliforme, oval, concave, deciduous leaves. COROLLA, nine oblong, concave, obtuse petals, narrow at the base. STAMINA, numerous short filaments inserted into the base of the pistillum, and linear antheræ attached to the sides of the filamentum. PISTILLUM, numerous oblong-oval germina, very short, recurved, contorted styles, and longitudinal hairy stigmas. PERICARPIUM, an oval strobilus, or cone, composed of compressed, roundish, almost imbricated, clustered, unilocular, bivalvular capsules, each containing one roundish, baccated seed, hanging by slender threads from the scales of the strobilus.

There are but four species, all of the tree

kind, one of them an ever-green, and one of the most beautiful in the world; the other three are deciduous, and also very beautiful. All the sorts, though originally of American growth, prosper in our gardens in the full ground all the year; they, however, being somewhat tender while young, require protection from frost, but afterwards may be turned out into the principal shrubbery plantations in the most conspicuous parts, where they will appear exceedingly ornamental in their fine luxuriant foliage, in some resembling the noble leaves of laurel, but much larger, as in some sorts they are near a foot long and almost half as broad.

Ever-green Kind.

This is a noble tree, very distinguishable from all others, yet known by its singularly large, and beautiful shining leaves.

MAGNOLIA Grandiflora.

Greater Grandiflorous Ever-green Magnolia.] Riseth with an upright stem, branching out upward into a regular head, seventy or eighty feet high; garnished with very large, spear-shaped, thick, firm, close-fitting, ever-green leaves, eight or ten inches long, and near half as broad, of a shining green above, and paler underneath; and from the ends of the branches, large pure-white flowers, of nine or ten broad-spreading petals; succeeded by oval, cone-like fruit, which never ripen in England.

Variety.] With leaves of a shining-green above, and of a rusty colour underneath.

Deciduous

Deciduous Kinds.

These sorts though deciduous are most beautiful trees, when in foliage, and elegant furniture for the best shrubberies.

²MAGNOLIA *Glauc.*

Glaucous-leaved Deciduous Magnolia.] Rises with an upright slender stem, branching ten or fifteen feet high, having a smooth white bark; oval-oblong, deciduous leaves, three or four inches long, of a glaucous hoary colour underneath; and from the extremity of the branches white flowers, succeeded by conic strobilus fruit, which never ripens in England.

This sort is remarkable for retaining its leaves great part of winter, appearing like an ever-green.

³MAGNOLIA *Tripetala.*

Tripetalate Magnolia, or Umbrella-tree.] Rises with an upright stem, branching about twenty feet high; very large lanceolate leaves, disposed in circular rays horizontally, in form of an umbrella; and large white flowers, having the outer petals dependent.

The name Umbrella-tree is derived from the disposition of its admirable large foliage, so as to resemble the form of an umbrella.

⁴MAGNOLIA *Acuminata.*

Acuminate Long-leaved Deciduous Magnolia.] Rises with an upright stem, branching fifteen or twenty feet high, having a smooth light bark; large oval-oblong, acuminate-pointed leaves, eight or ten inches long, and half as broad; and white flowers, having from nine to twelve petals; succeeded by conical fruit, not ripening in England.

All these four species of Magnolia are admirable fine ornaments for the principal shrubbery compartments; the grandiflorous kind also for the green-house, which is the most beautiful of all the sorts; but all of them are remarkably ornamental in their large elegant foliage, which are universally simple, entire, and almost sessile; and all the species after having acquired some considerable age and size, produce flowers here annually in June or July, are large, of a snowy white, and remarkable fragrance; and sometimes on old trees are succeeded by the formation of fruit, but it never acquires maturity in this country.

The flowers of all the sorts in their characteristic state, consist each of nine oblong obtuse petals, and numerous filaments and germina, &c. see the *Characters*.

In the American woods where these trees grow naturally in great abundance, the flowers are numerous on each tree, continue a long time in bloom, and perfume the whole woods with their agreeable odour.

All the four species are of somewhat tender temperature, and liable to injury from frost while young, the *Magnolia Grandiflora* most of all; but none of them, however, so tender but that they may be naturalized to this climate, after having occasional protection in winter during their infant state, by keeping them in pots three, four, or five years, in order to move to shelter of a frame or green-house in frosty weather; observing that the grandiflorous kind need this care the longest of any, the seedling plants of which generally requiring to be five or six years old before they can be trusted in the full ground finally; the other three sorts, as they drop their leaves in autumn, their shoots become more hardened, and not so subject to the rigours of frost, will generally succeed in the open ground after the second or third winter; but all the sorts should be gradually hardened by exposing them constantly to the full air summer and winter, in all mild or open weather, and only give shelter from frost; and when transplanted into the full ground, it should be done in March; but some of the ever-green *Magnolia* should also be retained in pots as green-house plants.

The grandiflorous ever-green Magnolia is one of the most beautiful trees in nature, both in the procerity and grandeur of its growth; and in its luxuriant noble leaves, which renders the tree singularly conspicuous and distinguishable, at all seasons, and may be considered the finest ornamental ever-green yet known, both for the shrubbery and green-house. Remarking, as already observed, that as the trees of this sort are impatient of frost whilst young, they should be kept in pots a few years, in order to have shelter of a garden-frame or green-house occasionally in winter, when frosts prevail; and even when those intended for the shrubbery are turned out into the full ground, it is proper also to erect a sort of frame-work of pliable poles, &c. arch-wise over each plant, in November, for the support of a covering of mats in rigorous weather, for a few winters: it is likewise proper, as before noticed, to retain some in pots, to be managed as green-house plants; and if those in the full ground should suffer by the frost, these will remain unhurt, and be

be as a reserve; observe, however, with respect to those in the full ground, to endeavour to naturalize them gradually as much as possible, to stand our ordinary winters without covering, which undoubtedly may in time be effected, especially those plant raised by layers and cuttings from plants, which have been of some years standing in the open ground.

The deciduous *Magnolias* are also remarkably ornamental trees, and ought to be introduced into every curious collection in shrubberies, where by their admirable fine foliage, they will exhibit an elegant variety. All these deciduous sorts after having occasional shelter two or three winters in their minor state, will succeed tolerably in the open ground all the year without covering.

All the species, both ever-green and deciduous, are cultivated in the nurseries for sale, of which the first sort, as being the most beautiful, and requiring more care in its culture, is generally pretty high rated.

The best season for planting all the sorts is in February and March, before they begin to make an effort for shooting, though as those sorts which are in pots may be turned out with the ball of earth about their roots, so as scarce to feel their removal, they may be occasionally transplanted in October or beginning of November; I, however, should generally prefer the spring-planting that they may be both firmly rooted, and inured to the soil, situation, and full air before winter.

Observe, that in the disposition of all the sorts in the shrubbery, as they are rather of a tender nature in their younger growth, it is proper to allot them a sheltered sunny situation, and dry soil; and all of them should be stationed in the most conspicuous point of view; and not too closely crowded with shrubs of inferior merit; they have also an admirable effect disposed singly in different parts, particularly in open spaces of grass-ground in the internal parts of the shrubbery plantations, the *Magnolia Grandiflora* in particular appear beautiful in this mode of disposition; observing of this sort, that wheresoever stationed, to allow it the occasional shelter of an awning of mats in frosty weather, as before noticed.

Propagation, &c. of all the Sorts.

The propagation of all the sorts is by seed, also by layers and cuttings.

By Seed.—This is received annually from America, preserved in sand, and commonly arrives here early in spring, which should be sowed as soon after as possible in pots of light rich earth, half an inch deep; and the pots then either plunged in a moderate hot-bed, just to bring up the plants an inch or two high, or may be plunged in common earth under a warm wall or hedge, or in a frame, in the full sun till the middle or latter end of April, then replunged in an easterly border open to the morning sun; giving moderate sprinklings of water in dry weather, and the plants will rise the same year, those having aid of a hot-bed, probably in April, and the others in May; observing to inure those in the hot-bed timely to the full air. All summer let the seedlings raised by either method be very regularly supplied with water; at the approach of winter remove the pots into a green-house, or rather under a garden-frame, there sheltered from frost all winter, but indulge them with the open air all mild weather. In March if the pots are plunged in a bark hot-bed, under a frame two or three months, it will forward the seedlings greatly, being careful to give water, and harden them to the open air gradually, so as to be removed into it fully in June, to remain till October, then allow them shelter in winter as aforesaid. Spring following plant them into separate pots, and plunge them into a hot-bed as above, to set them forward, giving water, occasional shade, and the benefit of the free air; and in June remove the pots to a shady border for the remainder of the summer; in winter give them shelter, as before, from severe frost, but to have the full air in all open weather. The same care may be proper for two or three winters, when some of them may be turned out of the pots with the ball about their roots, into the full ground in a warm place, especially the deciduous kinds; but the grandiflorous or ever-green sort, being tender, must not be too soon committed to the winter's cold, they should, therefore, be continued in occasional shelter, as above, four or five years at least, and when turned out into the open ground, it is proper to mat them occasionally, as already hinted, in severe winters; still retaining some in pots to be managed as green-house plants.

By Layers.—All the sorts may also be propagated by this method, which may be performed in autumn or spring: chuse the young pliable shoots, give them a gentle twist, or a slit

M A L

slit in the part to be layed, and lay them in the usual method: some will be rooted in one year, others probably not in less than two; then in March take them off and plant each in a pot, plunge them in a moderate hot-bed for a month or two to set them a-going freely at first, and they will form good strong plants by autumn, allowing them shelter in winter for a year or two, then may be transplanted into the full ground.

By Cuttings.—This may be effected by aid of a bark-bed, particularly that in the stove, &c. In March or April plant some short young shoots of the preceding year in pots, plunge them to the rims in the hot-bed, giving water and occasional shade, many of them will be rooted the same year, when they must be inured by degrees to the open air, afterwards managed as the layers.

MALPIGHIA, Barbadoes Cherry.

The plants are shrubby ever-greens of the warm parts of America, &c. retained here in stoves for variety; rising with branchy stems, from eight or ten to fifteen or twenty feet high, ornamented with oval and lanceolate entire leaves, and large pentapetalous flower, succeeded by baccaceous, cherry-shaped, red, eatable fruit.

Class and order, *Decandria Trigynia*.

Characters.] **CALIX**, is small, five-leaved, connivent and permanent. **COROLLA**, five reniforme, concave, spreading petals, having long narrow unguis. **STAMINA**, ten broadish, subulate, erect filaments, and heart-shaped antheræ. **PISTILLUM**, a roundish germen, three slender styles, and obtuse stigmas. **PERICARPIUM**, a large globular, furrowed, unilocular berry, containing three angular, rough, stoney seeds.

There are eight or nine species, those of them chiefly found in the English gardens are;

¹**MALPIGHIA** *Glabra*.

Glabrous-leaved Malpighia, or Common Barbadoes Cherry.] Rises with a shrubby, erect, slender stem, branching fifteen or twenty feet high; oval, entire, very smooth, opposite leaves; and from the sides and ends of the branches long foot-stalks, each sustaining an umbellate cluster of rose-coloured flowers; succeeded by roundish, baccaceous, red, cherry-like fruit.

²**MALPIGHIA** *Punicifolia*.

Pomegranate-leaved Malpighia] Riseth with a shrubby erect stem, branching diffusely eight or ten feet high; oval, entire, smooth,

M A L

opposite leaves; and from the sides and ends of the branches shortish foot-stalks, each sustaining one pale-red flower; succeeded by round baccaceous fruit.

³**MALPIGHIA** *Urens*.

Stinging Malpighia.] Rises with a shrubby robust stem, branching fifteen or eighteen feet high; oblong-oval leaves, covered underneath with bristly, decumbent, stinging hairs; and from the sides of the branches aggregate foot-stalks, each sustaining one purple flower; succeeded by oval, red fruit.

All these shrubs retain their leaves the year round; and begin flowering here about the end of autumn, continuing in constant succession till spring, exhibiting a fine variety in the stove, where they are frequently succeeded by ripe fruit, which in most sorts is of the size and shape of a small cherry; is of an acid palatable flavour, and in the West Indies, where the shrubs grow naturally in vast plenty, the fruit is eaten by the inhabitants instead of cherries; but those of the first sort are in most esteem.

As the plants are natives of hot countries, they require a hot-house here, so must be always be kept in pots of rich earth, and retained in the stove, except about a month or two in the heat of summer, when they may be placed abroad; observing to supply them duly with water all the year.

Their propagation is by seed; sow it in spring, in pots of rich earth, and plunge them in a hot-bed; and when the plants are three or four inches high, prick them in a separate small pots, give water, and plunge them in the bark-bed in the stove, where let them remain a year or two, then may be placed in any part of this department.

MALVA, Mallow.

This genus consists of herbaceous perennials, biennials, and annuals, for medical uses, and for ornament in gardens; and a shrubby plant for the green-house, rising mostly with erect stalks, from about half a yard to ten or twelve feet high, in different sorts; garnished with large, roundish, lobated leaves, and quinquepetalous flowers.

Class and order, *Monadelphia Polyandria*.

Characters] **CALIX**, is double, the exterior part is of three heart-shaped leaves, the interior is monophyllous and five-parted at the brim. **COROLLA**, is five obcordate plane petals, coalescing at their base. **STAMINA**, numerous monodelphous filaments, inserted into

into the corolla, and kidney-shaped antheræ. PISTILLUM, an orbicular germen, short cylindric style, and many bristly stigmas. PERICARPIUM, a round depressed head, composed of numerous arilli, or seed covers, each having one kidney-shaped seed.

There are upwards of twenty different species, but not more than four or five generally known here; three or four of which are hardy herbaceous plants, and one shrubby exotic for the green-house.

Hardy Herbaceous Kinds.

The first and second of these kinds, is the common Mallows of the field, for medicinal purposes, the others are sometimes kept in gardens for variety.

¹MALVA, *Sylvestris* (perennial).

Common Wild Upright Mallow.] Hath a long, fibrated, tough, deeply-striking root; upright stalks, two or three feet high; garnished with roundish seven-lobed leaves, having the lobes acute; and many reddish-purple flowers from the sides of the stalks.

Varieties.] With jagged leaves—with white flowers—with blue flowers.

This is perennial in root, but annual in stalk, grows wild every where: its root, leaves, flowers, and seed, are all medicinal.

²MALVA *Rotundifolia*.

Round-leaved Prostrate Wild Mallow.] Hath prostrate, or declinated stalks; roundish cordate, obsoletely five-lobed leaves, and purplish flowers.

This also grows wild, as the former.

³MALVA *Alcea* (Biennial).

Malva Alcea, or Vervain Mallow.] Hath long fibrated roots; upright stalks, branching two feet high; garnished with large, many-parted, roughish leaves; and large bright-red flowers from the sides of the stalks.

Varieties.] With downy leaves—with white flowers.

This sort and varieties are all biennial, and grow wild in some parts of England.

⁴MALVA *Moschata*.

Malva Moschata, or Jagged-leaved Vervain Mallow.] Hath long fibrated roots; reniforme, deeply-cut, radical leaves; upright stalks, branching about two feet high; garnished with five-parted leaves, having the lobes pinnated into many parts; and large red flowers.

Varieties.] With roundish leaves—curled leaves—with white flowers.

They are all biennial, and grow wild here in some parts.

⁵MALVA *Crispa* (annual).

Curled-leaved Syrian Mallow.] Rises with an upright strong thick stalk, six or eight feet high; closely garnished with large, angular, curled leaves, having the edges curiously furbelowed; and from the axillas glomerated clusters of reddish flowers.

This is an annual of Syria, but hath been long retained in our gardens for ornament.

All the above five herbaceous Mallows flower in June, July, and August, succeeded by great plenty of seed in autumn.

Shrubby Green-house Kinds.

⁶MALVA *Capensis*.

Cape Shrubby Mallow.] Rises with a tree-like, erect, thick, durable stem, ten or twelve feet high, branching out laterally the whole length, the branches numerous and hairy; garnished with subcordate, laciniated, smooth leaves; and from the sides of the branches, large deep-red flowers; appearing great part of the year.

Variety.] Gooseberry-leaved Cape Shrubby Mallow.

With respect to the merit of all these six species of Malva, take the following hints.

As to the five herbaceous kinds; the two first of them are exceedingly useful in medicine, particularly the *Malva Sylvestris*; but they both growing wild all over England, and being most troublesome weeds, are rarely admitted into the gardens; but the third and fourth sorts, although they grow naturally also in some parts of England, are introduced into many gardens for ornament and variety, and they effect a very conspicuous diversity in assemblage with other plants of similar growth; and the *Malva Crispa* is likewise, very proper to increase the variety in large pleasure-grounds, which it effects most agreeably in the procerity of its growth and beautifully furbelowed leaves.

And the Cape Shrubby Mallow is very ornamental, and green all the year, but being a native of Africa, requires shelter in winter, therefore must be kept in pots of good earth, and placed in the green house collection.

Propagation.

All the herbaceous kinds are raised plentifully from seed. Sow them in spring, in a bed

bed or border of any common earth, either in patches where they are designed to flower, half an inch deep, or in a bed, and raked in, for transplantation, which should be performed when the plants are three or four inches high; though I should advise the annual sort in particular to be sowed in patches where the plants are to remain: several seeds in each patch, but leave only two or three of the best plants to grow to perfection.

The shrubby kind is also easily raised from seed in spring, but should have the aid of a hot-bed, and when the plants are about three inches high, plant them in small pots, harden them by degrees to full air, afterwards manage them as other green exotics.

MAMMEA, Mammee-tree.

There are but two species, both large ever-green trees of the hot parts of America and Asia, and retained here in hot-houses for variety; both of them adorned with large oval-oblong stiff leaves, and large quadripetalous, flowers, succeeded by large round eatable fruit, of a most exquisitely rich flavour.

Class and order, *Polyandria Monogynia*.

Characters.] CALIX, is monophyllous, two-parted and deciduous. COROLLA, four large concave spreading petals. STAMINA, numerous short filaments, and oblong antheræ. PISTILLUM, a roundish depressed germen, cylindric style, and a capitated permanent stigma. PERICARPIUM, a large spherical, baccaceous, fleshy, unilocular fruit, terminated by the style, and contains four sub-oval rough seeds.

The species are:

¹MAMMEA *Americana*.

American Mammee-tree.] Rises with an upright, robust, rough trunk, branching sixty or seventy feet high; large, oval-oblong, firm, splendid leaves, and having the stamina shorter than the corolla; and large round fruit.

²MAMMEA *Asiatica*.

Asiatic Mammee-tree.] Rises with an upright large stem, branching fifty or sixty feet high; covered with a cinereous, furrowed bark; large oval-oblong leaves; flowers, having the stamina longer than the corolla; and large tetragonous fruit.

Both these trees in their native soil produce abundance of fine fruit, as large as Catharine peaches, of a yellowish-green colour, and said to be of a delicate flavour.

The first sort grows in great plenty in the West Indies; and the other in Java.

In this country they require to be continued constantly in the stove, so must be kept always in pots, and placed in that conservatory, where they will cause a fine variety all the year with their large splendid foliage.

Their propagation is by seed, which arrives from America, &c. in spring. Sow it in small pots of light rich earth, and plunge them in the bark-bed, where they will soon come up; give gentle waterings, and about August transplant them into separate pots a size larger, plunging them in the bark bed, and give shade and water till fresh-rooted.

MANURE. This comprises all sorts of dungs, composts, and other materials proper for the improvement of land. See COMPOSTS, DUNG, &c.

Manure, therefore, is necessary to all soils, to repair them when exhausted by the growth of vegetables, and to cure the defects of soils naturally bad, such as to enrich and fertilize very poor land; to render very strong or stubborn land more light, loose, and pliable; and to render very light, loose, dry soils more compact and moist; and wet land drier, &c. strong moist land is the most improved by light manures, to open and loosen it; very light land by the more heavy and moist sort of Manure; and wet land by dry light composts; some soils require Manure annually, others but once in two or three years; all of which in respect to garden-culture is fully explained under the article DUNGS, &c.

The proper Manure for garden-ground being fully exhibited under the article DUNGS, it is needless to repeat it here.

But for corn-fields, &c. various sorts of Manure are occasionally used, according to the nature of the soil, and what different countries afford, as for instance:

All sorts of horse dung, neats dung, hogs-dung, farm-yard mulch; or a mixture of all or any of those together, suits almost all sorts of land; or a compost of any or all of those, and chalk, lime, earth, mud of ponds and ditches, cleanings of streets, ashes, rotten tanner's bark, rotten wood, and saw dust, rotten vegetables, &c. or such of any of these materials as can be had, and formed into a compost-heap to rot together, make a good Manure, both for corn and grass-land.

For the method of making compost heaps, see COMPOST.

Rotten tanner's-bark alone, or in compost, is good Manure for strong, cold, corn-land; and

and will also suit grass, if applied the beginning of winter, for the rains to wash it into the ground.

Rotten wood, and rotten saw-dust, is very proper for strong land.

Rotten vegetables, such as all sorts of weeds, and the refuse of kitchen-gardens, &c. laid in heaps, and if mixed with mud or any earthy substance, and the whole lie to rot, they will make a tolerable good Manure for corn-land.

Green fern mowed down and laid in heaps to rot, is also used as Manure.

Marle, chalk, lime, &c. properly prepared, either alone, or in compost, are greatly used in many places as a dressing for corn-land.

Sea-sand and shells, &c. being full of salts, are sometimes used as Manure for strong clayey and stubborn loamy soils.

Sea-weed is likewise employed as Manure, and, being full of salts, greatly improves corn-land.

Ashes of all sorts prove excellent Manure, especially to all strong cold or moist land; but coal ashes are superior to those of wood, or of any other kind of vegetables; the farmers in the counties round London have experienced this, and they fetch them from that city by cart and waggon-loads, twenty or thirty miles distance; for in London they in general using coal-fuel, prodigious quantities of ashes are daily made, and collected in carts and carried to the ash-hills in the environs of the city; where numbers of people are employed in sifting them, and sell the siftings by the sack or load to the farmers for Manure; also to the brick-makers for tempering their loam or brick-earth.

Bones of animals are also used as Manure for ploughed-land, where they are to be had in due quantities, as about London and other great cities.

Soot is also used as Manure to sprinkle thinly over corn-land.

Malt dust, containing a natural heat and sweetness, proves an eligible Manure to most sorts of land, but more particularly to stubborn, clayey, and sour harsh soils.

Cleanings of streets laid in compost-heaps with horse-dung, &c. makes excellent Manure both for corn and grass-ground.

All Manure for ploughed or digged-land, should be applied at the time the ground is to be tilled, and not spread about any long time before it is ploughed in, especially in

hot dry weather, which would exhaust the salts, and other enriching particles; observing, however, where any hard substances, as marle, shells, &c. are used for Manure, it is proper to spread them abroad some considerable time, exposed to the sun, rains, and frost, to pulverize, before they are ploughed into the ground.

The Manuring grass-land should generally be performed in autumn, about Michaelmas, or a little before or after, and not in the heat of summer, as is often practised, whereby the sun's heat greatly exhausts its moisture and goodness; but when done in autumn, the rain soon washes the enriching particles into the ground, to the great benefit of the grass, and encrease of the future crop.

MARANTA, Indian Arrow-root.

It consists of two herbaceous perennial exotics of the Indies, kept here in hot-houses for curiosity; have thick, knotty, creeping roots, crowned with long, broad, arundaceous leaves, ending in points, and upright stalks, half a yard high, terminated by bunches of monopetalous, ringent, five-parted flowers.

Class and order, *Monandria Monogynia*.

Characters.] CALIX, is three spear-shaped leaves placed on the germen. COROLLA, is monopetalous and ringent, has an oblong, compressed, oblique, inflexed tube, the limb divided into six parts, the side ones large and represent a lower-lip. STAMINA, one membranous filament, resembling a segment of a corolla, and linear antheræ attached to the border. PISTILLUM, a roundish germen under the calix, simple style, and obsoletely trigonous stigma. PERICARPIUM, a roundish trigonous trivalvular capsule, and one oval hard seed.

The species are;

¹MARANTA *Arundinacea*.

Arundinaceous Maranta.] Hath a thick, knotty, creeping, fleshy root; crowned by long, broad-based, arundenaceous, or reed-like leaves, diminishing upward to a point; amidst them upright, divided, branchy stalks, two feet high, terminated by bunches of white flowers.

²MARANTA *Galanga*.

Galanga, or Indian Arrow-root.] Hath a thick, creeping, fleshy, juicy root; crowned by many smooth leaves, six or seven inches long; amidst them upright, simple, or undivided stalks, half a yard high, terminated by loose bunches of small white flowers.

Both

Both the sorts flower here annually in June and July, each flower consisting of one ringent, or grinning petal, six-parted at top. See the *Characters*.

The plants are perennial in root, but annual in leaf and stalk, sometimes, however, the leaves of the second sort abide most part of the year.

Both the species being natives of the hot regions of the Indies, in this country they must be potted, and always kept in the hot-house, plunging them mostly in the bark-bed, and refresh them with moderate waterings, but more frequent when in a growing state, and shift them into larger pots occasionally.

Their propagation is by parting the roots, and spring is the proper season, just before they begin to shoot; planting them in pots of light rich earth, and plunge them in the bark-bed.

In America the roots of the *Galanga* being used by the Indians to extract the poison communicated by their poisoned arrows, it derived the name of Arrow-root.

MARLE, a kind of clayey, or strong earthy substance, of a chalky nature, generally placed deep in the earth, and is of a fertile quality, by its salt and oily properties, and is used to manure land. See MANURE.

Marle is of different natures in different parts.

Some is nearly of the nature of fullers earth, and is of a fat enriching quality, and of which there is blue, grey, yellow, and red coloured; the blue is esteemed to be the best.

Some is a kind of soft stone, or rather of a slaty nature, of a blueish and grey colour, and is called stone or slate Marle, found commonly near river-sides, and sides of hills, &c. and though hard when dug, easily dissolves by rain and frost.

Clay Marle resembles a fat sort of clay or loam, and is sometimes mixed with chalk stones.

Spitting or delving marle, is of a compact, strong, fat temperature, generally of a brown colour; and is met with in the sides of hills, and in some wet boggy grounds.

There are some other sorts of Marle of less note, which lie very deep, and not so easily obtained.

The sure sign of the goodness of Marle is when it readily dissolves by wet or frost.

All the sorts of Marle are accounted good manure for improving light, loose, sandy land

in particular, especially the fat kinds of Marle, though it may be applied with success to most sorts of land, observing, however, to use it more sparingly on strong soils, lest it bind it too close; but to sandy ground there can be no danger, and proves one of the best dressings for such kind of land.

It is commonly laid upon the land as it is taken from the pits; but some burn it, when one load will go as far as three or four.

MARTYNIA, *Martynia*.

This genus consists of two tender herbaceous flowery plants of South America, an annual and a perennial, both for the hot-house; rising with erect stalks, garnished with oblong simple leaves, and terminated by short spikes of large monopetalous bell-shaped flowers.

Class and order, *Didynamia Angiospermia*.

Characters.] CALIX, is five-parted and withering. COROLLA, is monopetalous, bell-shaped, the tube ventricose, and the limb five-parted at top. STAMINA, two long and two short incurved filaments, and connivent connected antheræ. PISTILLUM, an oblong germen, simple style, and bilobed stigma. PERICARPIUM, an oblong, quadrangular, quinquelocular capsule, opening in two at top, and having oblong seeds.

The species are;

¹MARTYNIA *Annua*.

Annual Martynia.] Rises with an upright, robust, hairy, branching stalk, three feet high; garnished with large oval-oblong, angulated, entire, hairy, viscous leaves; and from the forks of the stalk, and ends of the branches, short spikes of large reddish-purple flowers.

²MARTYNIA *Perennis*.

Perennial Martynia.] Hath thick knotty roots, sending up several robust, simple, succulent, purplish stalks, a foot high; garnished with oblong, serrated, thick, close-fitting leaves; and terminated by short spikes of blue flowers.

Both the species flower here in July and August, and are very ornamental; each flower is of one bell-shaped petal, succeeded by large, oblong, thick, tough capsules, which in the annual sort ripen here in autumn, but the second seldom ripen seeds in England.

These two plants being inhabitants of the hottest parts of the world, will not succeed here without artificial heat, so require the aid of a hot-house.

In respect to their duration, the first continues but one season, the other several years by the root, but the stalks decay annually in autumn.

The first sort is propagated by seed, sowed in pots in spring, and plunge them in a hot-bed, or in the bark-bed in the stove, giving sprinklings of water; and when the plants are two or three inches high, plant them out in separate small pots, which plunge also in the bark-bed, allowing them shade and water; and when they are a little advanced in growth, shift them into larger pots, managing them as above.

The second sort is propagated by dividing the roots in spring, planting each off-set in a pot of rich mould, and plunged in the bark-bed.

It may also be encreased by cuttings or the stalks planted in pots, and plunged in the bark-bed.

MAS *Planta*, a Male Plant; a dioecious plant, which produces male flowers only. See the class *Dioecia*.

All the plants of this kind belong to the class *Dioecia*, and the plants of which have Male and female flowers always on separate roots, i. e. the Males on one plant, and the females on another; so that the plants furnishing the Male blossoms, are properly Male Plants, and those producing female flowers, are termed female plants. See FEMINEUS *Planta*.

Of this kind are spinach, hemp, *Myrica* *Menispermum*, and many others.

Male Plants never produce seed; which is produced only from the females; but both Male and female plants rise from the same seed.

MASCULUS *Flos*, a Male Flower; a flower of the classes *Dioecia* and *Monoecia*, which is furnished with stamina, &c. or Male organs; but not the pistillum style and stigma, the female organs. See STAMINA, PISTILLUM, and FEMINEUS *Flos*.

Male Flowers are produced either upon separate plants from the females, as in all the plants of the class *Dioecia*, or on the same plant with the females, as in cucumber, melon, and all other plants of the class *Monoecia*, so that Male and female flowers, separated on distinct plants, constitute the class *Dioecia*; and separated on the same plant, the class *Monoecia*; those of the latter are also androgynous, that is, a mixture of both Male and

female flowers on the same plant. See ANDROGYNA *Planta*, and the classes *Dioecia* and *Monoecia*.

MATRICARIA, Feverfew.

The plants are hardy herbaceous perennials of upright growth, valuable in medicine, and to ornament the pleasure garden, rising two or three feet high, garnished with compound pinnated leaves, and terminated by many compound radiated flowers.

Class and order, *Syngenesia Polygamia Superflua*.

Characters.] CALIX, a compound radiated flower, having a hemispherical general cup, composed of linear imbricated scales. COROLLA, the general flower is compound and radiated, having the disc composed of numerous funnel-shaped hermaphrodite florets, five-parted and spreading at top, and oblong flat female florets compose the radius. STAMINA, in all the hermaphrodites five short filaments and cylindric antheræ. PISTILLUM, an oblong germen, slender style, and in the hermaphrodites a bifid patent stigma, in the females two revolute ones. PERICARPium, none, many oblong naked seeds.

There are several species, but not more than one that have any particular merit, viz.

MATRICARIA *Parthenium*.

Common Feverfew.] Hath very fibrey clustering roots; crowned with numerous compound leaves; upright stalks branching on every side, two or three feet high; garnished with compound plane leaves, of seven oval folioles, cut into many parts; and all the branches terminated by many compound, radiated, white flowers, having a yellow disc.

Varieties.] With full double flowers—with semi-double flowers—with double fistular flowers—with a fistular disc and plane radius—with short-rayed flowers—with rayless flowers—with rayless sulphur-coloured heads—with finely curled leaves.

This species and all its varieties flower abundantly in June, each flower composed of numerous hermaphrodite and female florets, the former compose the disc, the latter the radius, or border, and which, in the double and in the fistulous kinds, are very ornamental in gardens, but of disagreeable odour, and are all succeeded by plenty of seed in autumn.

The plants are mostly perennial in root, though in some moist soils are rather biennial or but of two or three years duration.

They

They have all a disagreeable odour, but possess exceedingly great merit as medical plants, being very efficacious in many disorders, and for which properties they are worthy of a place in every garden.

Considered also as plants of ornament, all the doubles and fistular flowered kinds, and the curled-leaved sorts, are proper furniture for any of the compartments of the pleasure-garden, where in assemblage they will effect a very agreeable variety, and the flowers will continue a month or six weeks in beauty.

Propagation.

The propagation is by seed, parting the roots, and by cuttings.

By Seed.—All the varieties are tolerably permanent from seed, where they stand separate at a distance. Sow it in March and April, upon a bed or border of light earth, and rake it in; and when the plants are two or three inches high, plant them out in nursery rows, six inches asunder, to remain till autumn, then transplant them finally, and they will all flower the following summer.

By parting the Roots.—All the sorts may be propagated in plenty by this method; but is effectual for continuing any approved variety of the double-flowered and curled-leaved kinds, or any other sort; observing previous to this method of propagation, that in order to encourage the plants to afford slips, their flower-stalks, as soon as the flower begins to fade, should be cut down close, when the plants will more readily push out fresh heads, or off-sets at bottom, both for continuing the roots, and for propagation; and they may be slipped or divided for encrease, either in autumn or spring.

By Cuttings.—This, like dividing the roots, is the certain method for continuing any particular variety. The cuttings of the young stalks planted in spring or summer, in a shady border, in the usual way, will readily grow, and become good plants by autumn.

Remark: it is always proper to raise some of the best varieties every year or two from seed, as before directed, to supply the place of any old roots that may prove biennial.

MEDEOLA, Climbing African Asparagus.

The plants are herbaceous, one of which is a climbing exotic of Africa, cultivated here as a green-house plant; is adorned with pin-

nated leaves, and hexapetalous, spreading, revolute flowers.

Class and order, *Hexandria Trigynia*.

Characters.] CALIX, none. COROLLA, six oblong-oval, spreading, revolute petals. STAMINA, six awl-shaped filaments, and incumbent antheræ. PISTILLUM, three corniculated germens, three styles, and recurved stigmas. PERICARPIUM, a roundish, trifid, trilocular berry, and three heart-shaped seeds.

There are but two species, one of which a tall climber, the other a small erect plant; but it is the climbing sort that is usually cultivated, of which there are two varieties, both for the green-house.

MEDEOLA *Asparagoides*.

Climbing African Asparagus.] Hath roots composed of several oblong, fleshy knobs, united at top; sending up annually long, climbing, very branchy stalks, winding round any support four or five feet high; pinnated leaves, composed of oval, spear-shaped, alternate folioles; and from the sides of the branches white flowers, singly, and by twos on each foot-stalk.

Variety.] Narrow-leaved; having weaker stalks, and longer and narrower leaves.

Both the varieties flower here in October and November, each flower of six spreading, rolled petals, and the seed ripen in spring.

They are perennial in root, and annual in stalk, which generally die to the ground every summer, and new ones shoot up in autumn, continue their growth all winter, and exhibit their leaves and flowers in full vigour.

They must be potted in light rich earth, and placed among the green-house plants to have shelter in winter; afford them moderate watering all the year, and larger pots occasionally.

The propagation is by parting the roots; they furnish off-sets freely, and the proper time to take them off is in summer, when the stalks are decayed: plant each in a pot of good earth, and place them in the shade, and give occasional light waterings; they shoot up stalks in the end of August, or early in September; place sticks for them to twine upon, and in autumn move them into the green-house, where they will exhibit their foliage, and flower most part of winter.

MEDICAGO, (*Medica*) Medick.

This genus furnishes a shrubby ever-green for the green-house and shrubbery, herbaceous

annuals for the pleasure-garden, and that celebrated herbaceous perennial called Lucerne, for field culture, as fodder for cattle; all of them garnished with trifoliate leaves, and papilionaceous flowers.

Class and order, *Diadelphia Decandria*

Characters.] CALIX, is monophyllous, bell-shaped, and divided into five acute segments. COROLLA, is papilionaceous, consisting of an oval, entire, reflexed standard, two oblong-oval wings, and an oblong, bifid, obtuse, reflexed carina, bending from the vexillum. STAMINA, ten diadelphous filaments, and small antheræ. PISTILLUM, an oblong, incurved, compressed germen, short style, and small stigma. PERICARPIUM, a long, compressed, inflexed pod, inclosing several reniforme seeds.

There are many species, but not more than three which have merit for our collection, one shrubby ever-green, one herbaceous annual, and an herbaceous perennial.

Shrubby Kind for the Green-house and Shrubbery.

It is retained commonly as a green-house plant, but will also succeed in the full ground in a warm situation.

¹MEDICAGO *Arborea*.

Tree Medicago, or Shrubby Moon-trefoil.] Hath a shrubby stalk, branching numerous and erectly six or eight feet high, having the younger branches covered with a hoary silvery down; closely garnished with trifoliate, ever-green leaves, each composed of three small wedge-shaped lobes, hoary underneath; and from the sides of the branches, long foot-stalks, terminated by clusters of bright yellow flowers, succeeded by moon-shaped pods.

This is a beautiful ever-green and flowering shrub, and exhibits a plentiful bloom, from spring till autumn, and if sheltered in winter, continue in flower most part of the year.

It being a native of Italy, it, with us, is consequently a little tender, and requires shelter in winter, either of a green-house, or of a warm sheltered situation in the full ground, for it will live in the open air in the shrubbery in moderate winters; but as being rather impatient of severe frost, it is proper always to keep some also in pots to move to shelter among the green-house plants.

Herbaceous Annual Sort for the Pleasure-Garden.

There are several annual sorts, but not more than one proper as garden plants, which is comprehensive of several varieties, known in gardens by the names of Snails, and Hedgehogs, &c. so called from the different odd shapes of their seed-pods.

²MEDICAGO *Polymorpha*.

Polymorphous Medicago, or Snail and Hedgehog-trefoil.] Hath trailing herbaceous stalks, branching diffusely; garnished with trifoliate leaves, having indented stipulæ; and from the sides of the branches papilionaceous yellow flowers; succeeded by snail-shaped pods, of many different forms in the varieties.

Varieties] Common Snail Medicago, having large smooth pods, shaped and twisted like a snail—Hedgehog Medicago, having large prickly snail-shaped pods, being armed with spines, pointing every way like a hedgehog—with turbinated pods—with globular pods—with orbicular pods—with long crooked pods—with double pods—with clustered pods—with twisted pods—with jagged leaves.

All these plants are admitted into the pleasure-ground principally for the singularity of their seed-pods; they are very hardy, and easily raised from seed in the common ground.

They all flower, and exhibit their singular seed-pods in June and July, ripening seeds in autumn.

Herbaceous Perennial for Field Culture.

³MEDICAGO *Sativa*.

Cultivated Fodder-Medicago, or Lucerne.] Hath a strong fibrey, deeply-penetrating, perennial root; many upright, smooth, annual stalks, rising two or three feet high; garnished with trifoliate, alternate leaves, having spear-shaped lobes; and from the axillas racemous foot stalks of purple flowers; succeeded by contorted pods.

This species is in great estimation as an article of husbandry for fodder, and is now cultivated in fields in great plenty in many places, is of such quick growth, as often to afford four or five different cuttings every summer.

Varieties of it are] With yellow flowers—With saffron-coloured flowers—with violet-coloured flowers—with striped flowers.

Pro-

Propagation of three Species.

First sort.—The *Medicago Arborea* is propagated by seed and cuttings.

By Seed.—In March or April sow it on a warm border in shallow drills, half an inch deep; or, to bring them forwarder, may sow them in pots, and plunge them in a hot-bed just to bring up the plants an inch or two high, then harden them by degrees to the open air; in winter following, all of them raised in either method, require shelter from frost; and in spring plant some singly in pots, in order to be managed as green house plants, and plant some also out in nursery-rows, in the full ground in a dry warm situation, to take their chance the year round.

By Cuttings.—In March or April cut off some robust young shoots, form them into cuttings from six to eight or ten inches long, plant them in a bed of light rich earth, or, to forward them more, may plant some in pots and plunge them in a hot-bed; in either method, give occasional waterings, and shade from the mid-day sun; they will all be well rooted by the end of summer, and next spring they may be transplanted, some into separate pots for shelter in winter; others in nursery rows in the full ground.

Second Sort.—The *Polymorphous Medicago*, is propagated by seed, sowed annually where the plants are to remain, in the latter end of March or in April. Sow them in patches towards the fronts of the borders, several seeds in each, but when the plants come up, and a little advanced in growth, thin them to one or two of the best in each patch, they will all flower, and exhibit their seed-pods in June and July.

Third Sort.—The cultivated *Medicago*, or Lucerne, is propagated by seed in open fields, sowed commonly in drills, where the plants are to remain; and once raised, is of many years duration.

This plant is now greatly extolled as a most excellent and profitable summer's fodder for all sorts of cattle; it comes up in great abundance, and is of such quick growth, as often to afford four or five different mowings from May until September; is generally given to the cattle green, cutting it down when from about ten to fifteen inches high, while the stalks remain soft and tender; it is also sometimes made into hay for winter use; though its chief uses is to cut and eat green; for which purpose there is scarcely any plant in

nature equal to it, as considering, in the first place, it presents itself very early in spring, before any other green fodder can be had, and during summer affords several distinct mowings for all sorts of cattle; therefore in consideration of the goodness of the nature of the plant as fodder, and the great abundance it affords, it highly merits culture, and succeeds in almost any soil, and the same crops continue good for many years.

It prospers best in light dry soils, and in which it is of longest duration; for in strong, or very moist land, although it may flourish at first, yet it is often apt to go off in three or four years; whereas in suitable dry ground, the same crop will flourish for half a century, and often prospers well in any dry barren ground, where hardly any other crop will succeed.

But to proceed to its propagation, which, as already observed, is by seed in the spring of the year.

The ground is to be prepared for the reception of the seed by proper ploughing or digging; but for large quantities in fields, ploughing is the eligible tillage, repeating it as the nature of the land shall require; together with repeated harrowings, to render the soil fine for the reception of the seed, which should generally be sowed in shallow drills, and the proper season is March and April.

The seed is sold by most of the nursery and seedsmen from about eight pence to a shilling per pound, and from six or eight to ten or twelve pounds is sufficient for an acre of land; that is, by drill-sowing six or eight pounds will be enough; but by broad-cast, it will require ten or twelve.

Drill-sowing is the most commonly practised, and is the most commendable method of sowing this seed; therefore draw shallow drills scarce an inch deep, and half a yard or two feet asunder: sow the seeds in the drills thinly with an even hand, and cover them in evenly with the earth, the depth of the drills; but this method of drill-sowing is sometimes performed with a drill-plough, furnished with a hopper, for sowing the seed as the drills are formed, covering them in the above depth; some, however, sow the seed by broad cast, and harrow it in, as the most expeditious method; but by drilling, the plants standing distant in rows, affords a much better opportunity of cleaning the crop from weeds by broad-hoeing.

In either method of sowing, the plants will soon come up, and be ready for mowing in June or July.

Remark. However, the crop will require occasional cleaning from weeds: if in rows it may be expeditiously performed by broad-hoeing, which should be performed for the first time soon after the Lucerne comes up, and which must be repeated occasionally, especially after each mowing; but in broad-cast sown crops, the plants rising promiscuously, the hoeing cannot be so readily performed; it, however, must be done as well as possible, at the same time cutting up the weakest plants where too thick, leaving them all at proper distances for the broad-hoe to pass between, for the plants spread exceedingly, provided they have room, and each send up numerous stalks.

In June or July the Lucern will be grown fifteen or eighteen inches high, or more, and begin to flower, when the first mowing may be performed; and the plants shooting up again strongly, afford another cutting in autumn, which is all that should be performed the first year.

The second year, however, and every year afterwards, will afford three or four cuttings at least; early in May the first crop will be ready for mowing; which may be performed when the plants are about a foot high, or a little more or less; and in a month or five weeks interval, another such crop will be ready, and this succeeded by another, &c. but when designed to make it into hay, two or three crops may be sufficient; or it may be fed off occasionally with sheep in spring, summer, and autumn; but which should generally be taken off in winter, until about February or March.

MEDICINAL PLANTS. Plants that are used in medicine.

Vast numbers of plants possess Medicinal properties, and are used accordingly. A great many of which grow wild in this country, and great numbers are of foreign growth, and imported hither dried, from many different parts of the world; but many eminent medicinal plants are also cultivated here in our gardens, the principal sorts of which are fully treated of as they occur in the course of this work under their respective genera.

A list, however, of the principal Medicinal Plants of our gardens and fields collected into one point of view in this place, may be convenient in assisting the memory in selecting

the proper sorts for a collection, referring to their respective genera for their culture; we therefore exhibit in the following alphabetical arrangement, a list of the genera which furnish the most material Medicinal Plants, pointing out those species in each genera, by their respective specific names, which are the most commonly used, consisting of herbaceous, perennials, biennials, and annuals, and of some trees and shrubs; remarking, that some of most of the sorts are also valuable for other uses besides medicine; some for oeconomic uses, and some for variety and ornament in gardens; all of which are illustrated under their proper heads; observing also, that most of the sorts in this list are hardy enough to grow here in the open ground, some of which grow wild in the fields, &c.

The above list of Medicinal Plants, by being collected from the different parts of the work under one head, will greatly assist the memory

M E L

in making a collection of these kinds, or for procuring them for use; many of which however, possess a considerable share of merit for other domestic uses, as well as for variety and ornament in gardens, as before suggested; all of which, together with their general culture, is fully explained under their respective genera, as above, as they alphabetically arrange in the course of the work.

MELIA, *Azedarach*) Bead-tree.

This genus consists of some deciduous and ever-green exotic trees of the Indies, proper for the shrubbery, green-house and stove; rising near twenty feet high; adorned with large pinnated or winged-leaves, and clusters of pentapetalous flowers.

Class and order, *Decandria Monogynia*.

Characters.] CALIX, is small, monophyllous, and five-parted. COROLLA, five long, narrow, spear-shaped, spreading petals, a cylindric, monopetalous nectarium much indented at the brim. STAMINA, ten very small filaments inserted into the top of the nectarium, and small oblong antheræ. PISTILLUM, a conical germen, cylindric style, and capitated quadrivalvular stigma. PERICARPIUM, a globular drupaceous fruit, containing a roundish, five-furrowed, quinculocular nut, each cell having one seed.

There are but two species, one of which is a deciduous tree for the green-house and shrubbery, having an ever-green variety for the stove; and the other species is also of the temperature of stove-plants.

Shrubbery and Green-house Kinds.

¹MELIA *Azedarach*.

Azedarach, or common *Deciduous Bead-tree of Syria*.] Rises with an upright robust stem, branching widely all around, about twenty feet high; large bipinnated, or double-winged deciduous leaves, of numerous folioles, each wing terminated by an odd one; and from the sides of the branches long bunches of small blue flowers; succeeded by roundish oblong, deeply five-furrowed, yellowish fruit, not eatable.

The fruit of this plant in Catholic countries is strung like beads, to compose some sort of rosaries; whence the name of Bead-tree.

This shrub is cultivated here sometimes in the shrubbery, but more commonly as a green-house plant; for, being a native of hot countries, in these parts it is rather tender. Some should be kept in pots to have shelter in severe weather,

weather, as a reserve, in case those in the shrubbery should be destroyed.

It is very ornamental in its large, compound, doubly-winged foliage, which are often near two-feet long.

Hot-house Kinds.

Variety.] (Melia Azedarach.)

Ever-green Semperflorous, Common Bead-tree of Ceylon.] Hath an upright stem, branching widely all around, about twenty feet high; large bipinnated ever-green leaves; and long paniculated bunches of blueish flowers, succeeded by roundish purple fruit; flowers always, or at least most part of the year.

²*MELIA Azadirachta.*

Azadirachta, or Indian Bead-tree.] Hath an upright robust stem, branching widely, and grows twenty feet high or more, covered with a dark-purple bark; pinnated or singly-winged leaves, of five or six pair of oblong lobes, terminated by an odd one; and from the branches long paniculated bunches of white flowers; succeeded by oval, olive-shaped, purple fruit, not eatable.

The flowers of all these shrubs are, separately, small, each of five spreading petals; but many being collected into long clusters, they are tolerably conspicuous.

All the three species merit culture in every garden accommodated with proper conveniences, they being very ornamental in their pinnated foliage.

The first sort, however, will succeed tolerably in the open ground in a dry warm situation, though it is rather subject to be hurt by severe frost: it is nevertheless proper to have some always in every curious shrubbery, to take their chance of all weathers, where, by the display of their elegant bipinnated foliage, they will effect a very distinguishable variety: it is also proper to have some always in pots, and managed as green-house plants, both to encrease the variety, and be as a reserve in case those fully exposed should be killed in severe weather.

But the other two sorts, the ever-green variety of the common Bead-tree, and the *Azadirachta*, being natives of very hot countries, require the almost constant aid of our stoves here.

The propagation of all the sorts is by seed, assisted by hot-beds.

First Sort.—The seeds are obtained from abroad, and generally arrive in spring, which

sow in pots of light rich earth, and plunge them in a hot-bed of tanner's-bark or dung, under frame and glasses; in which they will come up in a month or six weeks, giving frequent waterings, and fresh air; and in June should be fully exposed in a moderate shade until October, then placed under a frame, &c. there to enjoy the free air all winter in open weather, and sheltered from frost; and in March following plant them in separate small pots, which plunge in a bark-bed, &c. tho' this is not absolutely necessary, but if practised, it will greatly facilitate their rooting and first effort of growth; observing to indulge them freely with fresh air; and in June, as before observed, move them into it fully for the remainder of the summer, and allow them shelter again in winter, as above: which after being repeated three or four years, shifting them occasionally into larger pots, some of the strongest and most woody plants may be committed to the full ground under a warm wall, or in a dry sheltered part of the shrubbery; and the proper season for this work is the first fortnight in April; reserve a quantity also in pots to have the management of green-house exotics, lest those in the open ground should be cut off by the frost.

Second and Third Sorts.—Both these sorts are also propagated by seeds, sowed in pots and plunged in the bark-bed, and managed nearly as the first sort, only as being of much more tender quality, must be kept always in pots, and plunged in the tan-bed in the stove during their infant state; afterwards, having acquired some considerable size and strength, they may be placed in the open air for about two months in the heat of summer, and the rest of the year in the hot-house; manage them as other woody exotics of that department. See STOVE PLANTS.

MELIANTHUS, Honey-flower.

Two tall, ligneous, floriferous, perennial exotics for the green-house and shrubbery, constitute this genus, rising with durable ligneous stalks, four or five feet high or more; ornamented with large winged leaves; and terminated by long spikes of tetrapetalous flowers.

Class and order, *Didynamia Angiospermia.*

Characters.] CALIX, is large, unequal, five-parted, and coloured. COROLLA, four spear-shaped, narrow, spreading, reflexed-pointed petals, and a monophyllous, short, compressed, indented nectarium, situated in

the lower segment of the calix. STAMINA, two long and two short filaments, and oblong, heart-shaped antheræ. PISTILLUM, a four-cornered germen, erect style, and quadrifid stigma. PERICARPIUM, a quadrangular, semi-quadrifid capsule, having acute distinct angles, and divided by partitions into distended cells, each having one globular seed.

There are but two species, both natives of Africa, and being rather of a tender nature, are very commonly treated as green-house plants; but they will also often succeed all the year in the open-ground, in warm dry situations; it is, however, proper to cultivate some by both methods.

The species are;

¹MELIANTHUS *Major*.

Major Melianthus, or Honey-flower.] Hath a thick, ligneous, spreading root; many upright, ligneous, durable stalks, rising six or eight feet high; garnished with large pinnated leaves, of four or five pair of serrated lobes, terminated by an odd one, and have single stipulæ growing close to the foot-stalks; and from the sides and top of the stalks long spikes of chocolate-coloured flowers.

²MELIANTHUS *Minor*.

Minor Melianthus.] Hath a thick, ligneous, somewhat, spreading root; upright, ligneous, soft, durable stalks, rising four or five feet high, garnished with smaller pinnated leaves, of four or five pair of folioles, terminated by an odd one, and have two distinct stipulæ; and from the sides and ends of the branches long, loose, pendulous bunches of flowers tinged with green, saffron-colour, and red.

Both the species flower about June; each flower is of four spear-shaped spreading petals; and each plant produces many flowers annually, but rarely are succeeded by seeds in England.

The plants are very ornamental, both in foliage and flowers, and merit admittance in every collection.

They are durable both in root and stalk, for although the stems are somewhat of an herbaceous nature, they become woody and abiding, more especially if sheltered occasionally in winter; but those fully exposed are sometimes killed down to the ground in severe weather, but the roots generally remaining sound, send up new stalks again in the following spring.

Considered as green-house plants, it is proper to keep some always in pots to have shelter in winter, in case those in the open ground should be destroyed.

And for the pleasure-garden, plant some in a dry soil, in a sheltered warm exposure.

Their propagation is easily effected by suckers, and cuttings.

By Suckers.—These rise in tolerable plenty from the root, especially of the first sort; and may be taken up in autumn or spring, with fibres, and planted some in pots for the green-house, others in a warm dry part of the nursery, &c.

By Cuttings.—In spring or summer take off a quantity of young cuttings towards the tops of the stalks or branches, plant them in pots, and plunge them in a hot-bed, giving waterings, they will readily put out roots: or in default of a hot-bed, cover them close with hand-glasses, giving occasional shade, they will also take root; managing them afterwards as directed for the suckers.

MELISSA, Baum, or Balm.

It furnishes hardy, fibrous-rooted, herbaceous perennials, for medical uses, and variety in gardens, rising with upright slender stalks, from one to two or three feet high, garnished with simple, oblong, opposite leaves, and verticillate clusters of small monopetalous ringent flowers.

Class and Order, *Didynamia Gymnospermia*.

Characters.] CALIX, is monophyllous, bell-shaped, angular, bilabiated at top, and permanent. COROLLA, is monopetalous, with a cylindric tube, and ringent above; having the upper lip short, round, erect, arched, and indented in two, the lower one trifid, with the middle part largest. STAMINA, two longer and two shorter filaments, and small antheræ that join by pairs. PISTILLUM, a quadrifid germen, slender style, the length of the corolla, situated with the stamina, under the upper-lip, and a bifid reflexed stigma. PERICARPIUM, none; four naked seeds lodged in the permanent calix.

There are several species, but the following perennials are the only sorts for general notice.

¹MELISSA *Officinalis*.

Common Officinal Baum.] Hath fibrey perennial roots; many upright, square, branchy, annual stalks, rising two or three feet high; garnished

garnished with oblong, indented, opposite leaves, by pairs, two or three inches long, and half as broad; and from the upper axillas verticillate clusters of small white flowers, upon single foot-stalks.

Variety.] With variegated leaves.

The common Baum is a valuable medical plant, the virtues of which are universally known, and ought to be allowed a place in every garden, and may be encreased in great plenty by parting the roots.

The variegated kind exhibits an agreeable variety in the pleasure garden.

²MELISSA *Grandiflora*.

Grandiflorous Melissa, or Hettrurian Calamint.] Hath fibrey perennial roots; upright annual stalks, rising about a foot high; garnished with oblong-oval, indented, hairy, opposite leaves; and from the upper axillas verticillate clusters of large purple flowers, on forked foot-stalks.

³MELISSA *Calamintha*.

Common Calamint of the Shops.] Hath fibrey perennial roots; upright, square, branchy, hairy stalks, rising a foot high; roundish, indented, opposite leaves; and verticillate clusters of small blueish flowers, on forked foot-stalks as long as the flowers.

All these three species of *Melissa* flower in June and July; each flower is of one ringent, labiated petal, and are disposed in a verticillus, or whorls, in small heads, or clusters, going quite round the stem, on short foot-stalks (see VERTICILLUS); and are succeeded by ripe seeds in autumn, but these are hardly ever wanted, since all the sorts multiply greatly by root.

They are all perennial in root, but annual in stalk, and all so hardy as that they will grow in almost any soil and situation.

The plants are fragrant, warm, and accounted cordial and cephalic; their chief virtue resides in the leaves.

As to their merit in gardens, they are proper both for use and ornament.

The *Melissa Officinalis*, or common Baum, merits a place in every garden for its admirable medical qualities, as well as for some culinary uses; is easily propagated by slipping the roots, and should be disposed in the kitchen-garden among the aromatics, in rows about a foot asunder (see the *Propagation*); and its variegated sort may be disposed in the pleasure-ground. So refreshing is the smell of both the varieties, so salutary and cooling when made into tea, by way of medicine, that they have the first claim to a place in our

gardens. Great quantities of the common green sort are cultivated in the gardens about London for supplying the markets, and is of such quick growth, that it often affords three or four cuttings each summer, to cut young for immediate use; though when wanted for principal medical purposes, or to dry for keeping, it should generally stand till arrived nearly at full growth, and just beginning to flower, then cut it in dry weather, and dry it in the shade, as directed for the mint. When any is designed for market, either young or at full growth, tie it in bunches, a good handful in each; which in London sell at from six pence to a shilling per dozen of bunches.

The second sort is commonly introduced into pleasure-gardens, as a plant of ornament and variety.

But the third sort is chiefly considered as a medical plant, though inferior to the common Baum, and as it grows wild in England, is rarely cultivated, except in physic gardens.

Propagation of all the Sorts.

The propagation of all the sorts is effected plentifully by parting the roots, which encrease exceedingly by off-sets annually.

Autumn or spring is the proper season for this work, though it may be done any time in open weather, from the decay of the stalk in autumn until spring, before new ones begin to arise; the most eligible season, however, is September or October, that the off-sets may take good root before winter, and be firmly established against spring; particularly the common Baum.

The method is, the whole root may either be taken up and divided into as many slips as are furnished with fibres; or the main root may stand, and slip off a quantity of off-sets around the out-side; plant those of the common sort, &c. for use, in the kitchen-garden, in four-feet wide beds, in rows of a foot or eighteen inches asunder, and a foot distance in each row; they will spread and encrease into large bunches the following summer, and afford a good cutting or two the same year; those intended for ornament or variety, such as the variegated common Baum, and the and the *Grandiflorous Melissa*, should be dispersed singly in the different compartments where they are wanted.

All the culture these plants require is keeping them clean from weeds: and cut down all remaining stalks in autumn; at which time also clear off all weeds from the beds of common

mon Baum, and dig the alleys and spread a little of the earth over the surface of the beds between the plants, whereby the beds will remain neat all winter, and it will prove beneficial to the plants.

A plantation of Baum will remain in good condition several years; though if renewed every third or fourth year, is the way to continue a succession of crops in full perfection.

MENTHA, Mint, Penny-Royal, &c.

The plants are hardy, herbaceous, aromatic perennials for the kitchen-garden, of admirable salutiferous properties, both for culinary purposes and medicine; have all creeping perennial roots, sending up stalks annually; some erect and two or three feet high, others trailing and scarce a foot long; all the sorts are garnished with simple, oblong, and oval leaves, and terminated by verticillate spikes, and clusters of numerous, small, monopetalous, tubulous flowers.

Class and order, *Didynamia Gymnospermia*.

Characters.] CALIX, is monophyllous, tubular, erect, five-parted, and permanent. COROLLA, is monopetalous, tubular, erect, and divided into four parts, the upper largest and emarginated. STAMINA, four didynamious filaments, and roundish antheræ. PISTILLUM, a quadrifid germen, slender style, and spreading bifid stigma. PERICARPIUM, none; four seeds lodged in the calix.

To this genus is now joined the *Pulegium*, or Penny-Royal.

There are many species of *Mentha*, most of which grow wild in this country by the sides of brooks, rivers, and watery ditches; but of which there are seldom more than three species cultivated, viz—common green Spear-Mint—Pepper-Mint—and *Pulegium*, or Penny-Royal.

The most material species are;

¹MENTHA *Viridis*.

Green Mint, or common Spear-Mint.] Hath long creeping very spreading roots; upright, square, single, green stalks, rising two or three feet high; garnished with oblong, serrated, close-fitting, smooth, very green leaves; and the stalks terminated by purplish flowers, in oblong erect spikes; the stamina longer than the corolla.

Varieties.] Broad-leaved—narrow-leaved—curled-leaved—variegated-leaved.

This is the species of *Mentha* the most commonly esteemed and cultivated in kitchen-

gardens for all culinary uses, as for sauces, salads, &c. and for several medical purposes: and the curled leaved and variegated sorts of it, are employed in the pleasure-garden for variety. It grows wild in England, but has been long cultivated in gardens, and is superior in quality to the two immediately succeeding species, which are also of the Spear-Mint kind.

The appellation Spear-Mint is derived from spear-like form of the spikes of flowers.

²MENTHA *Sylvestris*.

Wild, long, hoary-leaved Spear-Mint.] Hath long, thick, spreading root; upright, square stalks, two feet and a half high; oblong, serrated, hoary, close-fitting leaves; and the stalks terminated by pale-red flowers in oblong erect spikes, the stamina longer than the corolla.

³MENTHA *Rotundifolia*.

Round-leaved Spear-Mint.] Hath long spreading roots; upright stalks, two feet high; large, roundish, rough, crenated, close-fitting leaves; and the stalk terminated by flowers in oblong erect spikes.

These last two species, *Mentha Sylvestris* and *Rotundifolia*, grow wild here in moist places, are often distinguished by the names of Horse Mint; and are sometimes cultivated, though are supposed inferior to the first species, *Mentha Viridis*, which is very distinguishable from both these species; as also from the following:

⁴MENTHA *Piperita*.

Pepper-Mint.] Hath long, thick, creeping roots; upright, branchy, purple stalks, two feet and a half high; garnished with oval-oblong, serrated, dark-green leaves, having foot-stalks; and the stalks and branches terminated by purple flowers in roundish heads, the stamina shorter than the corolla.

This species is of a hot biting taste; is in universal estimation as a medicinal herb, greatly used for distilling, and of which is prepared that fine salutary cordial, called Pepper-Mint Water.

The following varieties of *Mentha* are of different species, and cultivated principally for variety—Orange Mint, having roundish leaves, smelling like orange-peel—gold striped orange Mint—yellowish orange Mint—reddish orange Mint—hoary white Mint—silvery spotted Mint—hoary variegated white and green Mint—variegated white and green, tinged with red. Most of these varieties are strongly

strongly scented, some like an orange, others resembling baum, and some like penny-royal.

Penny-Royal Kinds.

⁵*MENTHA Pulegium.*

Pulegium, or Penny-Royal.] Hath small, fibrey, very spreading roots; small, trailing, roundish, rooting stalks, spreading every way, taking root as they advance; garnished with small, oval, obtuse, crenated leaves; and the stalks terminated by verticilli of purple flowers, having the stamina longer than the corolla.

This species is a fine aromatic; it grows wild upon commons, &c. in many parts of Britain; and is cultivated in kitchen-gardens as a culinary herb.

⁶*MENTHA Cervina.*

Cervine Upright Penny-Royal.] Rises with erect stalks, branching on every side, a foot and a half high; garnished with linear or very narrow thickish leaves; and terminated by verticilli of purple flowers.

All these six species of *Mentha*, and respective varieties, are perennial in root, but the stalks rise in spring and decay in autumn.

They flower in June and July: the flowers are mostly very small, each of one tubular petal, of no beauty, and are succeeded by ripe seeds in autumn; but the seeds are rarely used, the plants being all generally propagated either by parting the roots, by young off-set plants, or by cuttings.

The plants are all exceedingly hardy, and prosper in any common soil of a garden.

They are all of a warm, fragrant, aromatic, and cordial nature, and their virtues reside in their stalks and leaves, and most of the Mint kinds possess excellent medical properties.

With respect to their particular merit as garden plants; the common green Spear-Mint is valuable both as a culinary and medical herb; but the Pepper-Mint principally for medical uses, and for which it is greatly esteemed, and is generally distilled: and the Penny-Royals are proper both for kitchen uses and medicine. Observing, that for all of which purposes they merit culture in every kitchen-garden, where they should be disposed chiefly in four-feet wide beds, having foot-and-a-half alleys between, the plants, placed in rows lengthways in the beds, six or seven rows in each, as directed in their propagation.

For kitchen uses the common green Mint and Penny-Royal are the most proper whilst young and tender, as in spring and beginning of summer; but by cutting down some of their stalks occasionally in summer and autumn, a succession of young shoots may be continued from Mint until October or November; and by the aid of hot-beds, young Mint may be obtained all winter until the common crop comes up in spring, as directed in their propagation.

But when any of the sorts of *Mentha* are required for drying to keep, or are wanted for distilling or other medical uses, they should be permitted to grow up to their full height, till just beginning to flower; they are then in the greatest perfection for those purposes.

When any of these plants are intended to be dried for keeping for winter use, cut them in dry weather, and spread them in a dry airy place to dry, but not in the sun, which would dry them too fast, and exhaust their goodness; therefore mark this, and spread them, or hang them up in bunches, where they may be out of the wet and sun, and dry gradually.

Propagation of the Mint Kinds.

Previous to the work of propagation we will in the first place just hint, that for the reception of all the sorts for use, prepare, in the kitchen garden, four-feet wide beds, having foot-and-half alleys between, for the convenience of going in to clean, water, and cut the crops, as also for earthing the beds a little in autumn, by way of dressing, both for neatness and to encourage the plants.

But to the propagation: all the sorts of Mint are propagated either by parting the roots, by young off-set plants, or by cuttings.

By Parting the Roots.—In autumn or early in spring, before the young shoots begin to appear, dig up from any old plantation a quantity of roots, and divide them into smaller parts, and of which chuse the strongest and freshest for planting; then proceed to plant them in drills, which draw with an hoe lengthways the bed, an inch and a half deep, and half a foot asunder, seven in each bed; and along the bottom of each drill place the roots of the mint thinly, covering them over with the earth, to the depth of the drills, then lightly rake the surface smooth, and the work is done.

They will readily grow, and afford plenty of young Mint the ensuing spring and summer.

ner for fallads, and culinary uses; also, if suffered to run up, will afford one or two good cuttings at full growth for drying, or for distilling.

By Young Plants.—In beds of Mint of some standing, young shoots rise numerously in spring, so as to admit of thinning; and a quantity of the most robust of which, drawn out with fibres at their bottom, form fine sets or plants for making a new plantation; therefore in April or May, when the shoots are advanced five or six inches long, take the opportunity of showery weather, and proceed to take up a quantity of the strongest, having a knife to assist in raising and separating them from the old roots, they will readily rise with roots to each; then proceed with line and dibble to plant them in rows, six inches apart, and four inches asunder in the rows, seven rows in each bed, each plant half way into the ground, and finish with a good watering, repeating it occasionally; and they will very soon take root, spread at bottom, and afford a full crop the same year.

By Cuttings.—In May or June, in moist weather, cut off a quantity of the strongest shoots or stalks near the bottom, and divide them into cuttings six inches long: plant them by dibble in rows, six inches asunder, in beds as above, give water directly, and repeat it in dry weather; they will soon take root, spread at bottom and produce a full crop the same summer.

The above three methods of propagation holds good with all the sorts of Mint.

Observe, however, those designed to form variety in the pleasure-garden should be disposed in patches in different parts.

A plantation of Mint for use, will afford several cuttings every summer, when it is only required young for present use, for culinary purposes; but when required for drying to keep till winter, or wanted green for medical use, they should generally be suffered to stand until July, till nearly full grown, and just coming into flower; which being then cut down close, the roots will send up another crop fit to cut again towards Michaelmas: each cutting, whether to be cut young, or when at full growth, should always be cut as close to the ground as possible.

When any is designed for market, bind them in bunches, a large handful in each, they sell at about nine pence or a shilling per dozen.

The general culture of all the sorts, is clearing them from weeds in spring and sum-

mer, cutting down all remaining stalks every autumn; clearing off also any autumnal weeds; and in October or November dig the alleys, and spread a little of the earth over the beds; this will give an air of culture and neatness, and prove beneficial to the crop.

A plantation of Mint, &c. will be of many years duration, but to have a constant succession of good full crops, a fresh plantation should be made every four or five years.

Forcing Mint for Winter Use.

Young green Mint is often required in winter for fallads, sauces, &c. but this can only be obtained by aid of hot-beds, and the common green Mint is the properest sort; therefore, any time in winter from November until the beginning of February, a hot-bed may be made for this purpose. Make it but moderate, about two feet thick of dung will be sufficient, and covered with garden-frames and glasses, or in default thereof, may be arched over and covered with mats; as soon as it is made and framed, earth it over with rich mould, six inches thick, then take up a quantity of roots out of the natural-ground bed, and spread them close together upon the surface of the earth of the hot-bed, and mould them over closely an inch deep with fine earth, and put on the lights, or if mat-coverings are used, cover only on nights, and bad weather; but frames and glasses are the most eligible for the middle of winter; observing to tilt the lights to let off the steam, and to admit fresh air: the plants will soon come up plentifully, when continue to admit fresh air in fine weather, and give moderate waterings, and they will soon be ready for use.

When the plants thus raised are an inch or two high, or a little less or more, they may be cropped for use; they will readily break out again, and fresh shoots rise from the bottom; so that the same bed will furnish a supply of plants a long time; and two beds made at different times, may be sufficient for the whole winter.

By the above practice of forcing Mint, you may obtain it young and green from the time the natural ground Mint goes off in autumn, until it comes in again in spring.

When it is, however, intended to force Mint every winter, a fresh plantation should be made annually in the open ground for that purpose, to furnish a sufficiency of roots fit to take up at forcing time, without disturbing those of the principal crop.

Penny-Royal Kinds.

Both the Penny-Royal species delight in a moist soil; they, however, will both prosper in any good earth of the kitchen-garden.

They are propagated in great plenty either by slipping their roots, in autumn or spring, or by cuttings of their rooting-stalks, which spreading upon the ground emit roots from every part; and shoots of them may be taken off plentifully in spring, each well furnished with roots; the slips or cuttings in either way, are to be planted by dibble, in rows a foot asunder; they will quickly set to growing, and spread about each way, and furnish a full crop for use in spring and summer.

Their culture is nearly the same as the Mint, and a plantation will be of several years duration.

MENISPERMUM, Moonseed.

It furnishes some hardy climbers of America, for the shrubbery, rising with climbing, ligneous, durable stalks, twining round any support twelve or fifteen feet high, garnished with roundish peltate leaves, and bunches of polypetalous dioecious flowers.

Class and order, *Dioecia Dodecandria*.

Characters.] **CALIX**, male and female flowers on separate plants, having a perianthium of two short narrow leaves. **COROLLA**, four exterior oval petals, and eight oval concave interior ones. **STAMINA**, twelve or more filaments in the males, and short quadrilobed antheræ, and in the females eight filaments, having the antheræ barren. **PISTILLUM**, two small, oval, incurved germina, solitary recurved styles, and bifid stigma. **PERICARPIUM**, two roundish, reniforme, unilocular berries, having one large reniforme seed.

The chief species are;

¹**MENISPERMIUM** *Canadense*.

Canada Round-leaved Moonseed.] Rises with several climbing ligneous stalks, twining upon support twelve or fifteen feet high; large peltated, cordate, roundish, angular leaves, on long twining footstalks; and from the axillas loose bunches of greenish flowers.

²**MENISPERMUM** *Virginicum*.

Virginian Lobated-leaved Moonseed.] Rises with climbing ligneous stalks, twining round support twelve or fifteen feet high; large peltated, cordate, lobated leaves; and loose bunches of greenish flowers.

Both these climbers flower here in July, each separate flower is of about twelve oval petals, four exterior, and eight interior

ones; and are succeeded by ripe seeds in autumn.

These plants are employed as climbers in the shrubbery to form a variety, placed to twine round the stems of trees, or any other support, or their numerous stalks and branches will twine and interweave one among another, and assume a bushy growth: it is, however, proper to allow them some support, for in America, their native soil, they climb up trees to a considerable height; so that here they are proper furniture for wilderness quarters to climb among trees and bushes.

Their propagation is either by layers in autumn, which will be well rooted in one year; or, as they spread exceedingly in root, sending up many shoots, which being separated in autumn, each with roots to it, they will form proper plants.

They may also be raised from seeds, sowed in spring in the open ground, half an inch deep; they will rise the same year, managing them as other hardy seedlings.

MESEMBRYANTHEMUM, (*Ficoides*) Fig-Marigold.

This genus comprises a numerous tribe of succulent, curious, floriferous exotics, of Africa, for the green-house collection, &c. consisting of one or two annuals, and many perennials; all of them with very succulent stalks and branches, some trailing and herbaceous, others erect and shrubby, and some acaulis; garnished with thick succulent leaves, of various singular forms in different species; and monopetalous multipartite flowers.

Class and order, *Icosandria Pentagynia*.

Characters.] **CALIX**, is monophyllous, acutely five-parted and permanent. **COROLLA**, is monopetalous, and deeply divided into many narrow spear-shaped segments in several series. **STAMINA**, twenty or more filaments, and capillary antheræ. **PISTILLUM**, an obtuse five-cornered germen under the corolla; and mostly five, but sometimes ten or more styles, with simple stigmas. **PERICARPIUM**, a roundish fleshy capsule, having as many cells as there are styles, with numerous roundish seeds.

There are between forty and fifty different species; all African plants from the Cape of Good-hope; near forty of which are retained in our gardens for variety, one of which is annual (Ice Plant); all the rest are perennial for the green-house collection; and all the sorts are of the succulent tribe, both in stalk and leaves, some with trailing stems, some with

with shrubby firm stems, others loose and pendulous, and some acaulis; and their leaves being mostly thick and fleshy, are of many different shapes, &c. in different species; some long and round like a cylinder, others three-square, some taper, some tongue-shaped, scymetar-shaped, &c. some opposite and connate, or connected at the base, and some distinct; many are papulose, or pimply, others punctated, or dotted; some impunctated, or intirely spotless, or smooth, &c. all as in their following descriptions.

Annual Sort.

¹MESSEMBRYANTHEMUM *Crystallinum.*

Crystalline Mesembryanthemum, commonly called Diamond Ficoides, or Ice-Plant.] Rises with a short, thick, succulent stalk, dividing low into many trailing, very spreading, succulent branches, bespangled all over with icy pimples, very pellucid and glittering; oval, undulate, alternate, papulose or pimply, glittering leaves; and from the sides of the branches numerous, almost close-fitting, white flowers, tinged with red or crimson; succeeded by plenty of seed in autumn.

This singular and curious plant being closely covered with large pellucid pimples, full of moisture, shining brilliantly like diamonds or bubbles of ice; whence it derives the name, as above; it is in great esteem by the curious for its singularity, and highly merits a place amongst the tender annuals of the pleasure-garden.

Perennial Sorts, all for the Green-House.

²MESSEMBRYANTHEMUM *Geniculiflorum.*

Jointed flowered Mesembryanthemum.] Hath a shrubby succulent stalk; half-taper, papulose or pimply, distinct leaves; and white flowers, sitting close to the axillas, having quadrifid cups.

³MESSEMBRYANTHEMUM *Noctiflorum.*

Noctiflorous, or Night-flowering Mesembryanthemum.] Hath a thick, shrubby, succulent stalk; half-cylindric, smooth, distinct leaves; and purple and white flowers on foot-stalks, having quadrifid cups; the flowers opening on nights.

⁴MESSEMBRYANTHEMUM *Splendens.*

Splendent, or Shining Mesembryanthemum.] Hath a shrubby, firm, succulent stalk and branches; semi taper, recurved, unspotted, smooth, shining leaves, growing distinct in clusters; and whitish flowers, having the cups terminating in digitate points.

⁵MESSEMBRYANTHEMUM *Umbellatum.*

Umbellated Mesembryanthemum.] Hath a shrubby, firm, succulent stalk; awl-shaped, rough-spotted leaves, connate at the base, but spreading at top; and white flowers in a corymbus resembling an umbel.

⁶MESSEMBRYANTHEMUM *Calamiforme.*

Calamiforme, or Quill-leaved Mesembryanthemum.] Is acaulis, or without stalk; almost taper, impunctated or spotless, ascending leaves, connate at the base; and octagynous, or eight-styled, white flowers.

⁷MESSEMBRYANTHEMUM *Bellidiflorum.*

Daisy-flowered Mesembryanthemum.] Is acaulis, or without stalk; narrow, three-cornered, spotless leaves, having the top indented into three parts; and small purplish flowers.

⁸MESSEMBRYANTHEMUM *Deltoides.*

Deltoid-leaved Mesembryanthemum.] Hath a shrubby, succulent stalk; deltoide-shaped, triangular, short, thick, indented, spotless, distinct leaves; and pale-purple, fragrant flowers, singly.

⁹MESSEMBRYANTHEMUM *Barbatum.*

Bearded Star-pointed Mesembryanthemum.] Hath a shrubby, firm, succulent stalk and branches; sub-oval, papulose, or pimply leaves, distinct, bearded at the point in a radiated manner; and purple flowers.

¹⁰MESSEMBRYANTHEMUM *Hispidum.*

Hispid, or Bristly Mesembryanthemum.] Hath a shrubby, firm, succulent, hispid, downy stalk; cylindrical, papulose, distinct leaves; and pale-purple flowers.

Varieties.] With violet-coloured flowers — with orange coloured flowers — red flowers.

¹¹MESEMBRYANTHEMUM *Villosum.*

Villose, or Hairy Mesembryanthemum.] Hath a shrubby, firm, succulent, hairy stalk; narrow, semi taper, channelled, downy, spotless leaves, connate at the base.

¹²MESEMBRYANTHEMUM *Scabrum.*

Rough-leaved Mesembryanthemum.] Hath a shrubby, succulent stalk; awl-shaped, distinct leaves, having all the under-side very rough and prickly; and violet-coloured flowers, with chaffy cups.

¹³MESEMBRYANTHEMUM *Emarginatum.*

Emarginated Mesembryanthemum.] Hath a shrubby, succulent stalk; awl-shaped, roughish leaves, in clusters; and purple flowers, having the petals emarginated, and with spinous cups.

¹⁴MESEMBRYANTHEMUM *Uncinatum*.

Uncinated Mesembryanthemum, or Buck's-horn Ficoides.] Hath a shrubby, jointed, succulent stalk; having the joints terminated by triangular, acute-pointed, connate leaves, indented underneath; and purple flowers.

¹⁵MESEMBRYANTHEMUM *Spinosum*.

Spinous, or Prickly Mesembryanthemum.] Hath a shrubby, succulent stalk and branches, armed with branching spines; taper, three-square, punctated, distinct leaves; and reddish-purple flowers.

¹⁶MESEMBRYANTHEMUM *Tuberosum*.

Tuberous-rooted Mesembryanthemum.] Hath a headed, tuberous root; shrubby, firm, succulent stalks; awl-shaped, blistered or pimply, distinct leaves, patulent or spreading at top; and purple flowers.

¹⁷MESEMBRYANTHEMUM *Stipulaceum*.

Stipulaceous Mesembryanthemum.] Hath a shrubby, firm, succulent stem; sub-triquetrous, compressed, punctated, distinct leaves, in clusters, having the base bordered; and purple flowers, nearly in a corymbus.

¹⁸MESEMBRYANTHEMUM *Craffifolium*.

Craffifoliate, or thick-leaved Mesembryanthemum.] Hath a nearly cylindrical, loose, creeping stem; semi-cylindrical, thick, smooth, connate leaves, triquetrous at the top; and purple flowers.

¹⁹MESEMBRYANTHEMUM *Falcatum*.

Falcated-leaved Mesembryanthemum.] Hath a shrubby, firm, succulent stem; sub-scymitar-shaped, incurved, punctated, distinct leaves; and purple flowers.

²⁰MESEMBRYANTHEMUM, *Glomeratum*.

Glomerated Mesembryanthemum.] Hath a shrubby, succulent, diffuse, paniculated stalk; taper, trigonal, compressed, incurved, punctated leaves; and numerous purple flowers in conglomerated panicles.

²¹MESEMBRYANTHEMUM *Loreum*.

Loreated Mesembryanthemum.] Hath a loose, pendulous, succulent stalk; semi-cylindrical, long, recurved, connate leaves, in clusters, having the interior part of the base gibbous; and reddish purple flowers.

²²MESEMBRYANTHEMUM *Filamentosum*.

Filamentose Mesembryanthemum.] Hath a pendulous, loose, succulent stem, dividing into hexagonal branches; triquetrous, slightly-punctated leaves, almost connate at their base, with rough angles; and small-petaled, obsolete-purple flowers.

²³MESEMBRYANTHEMUM *Acinaciforme*.

Scymitar-leaved Mesembryanthemum.] Hath a loose, procumbent stalk; scymitar-shaped, spotless, connate leaves, having angular rough keels; and purple flowers, with spear-shaped petals.

²⁴MESEMBRYANTHEMUM *Micans*.

Glittering Mesembryanthemum.] Hath a shrubby, firm, succulent, rough stem; sub-cylindrical, pimply, silvery, glittering, distinct leaves; and orange-coloured flowers.

²⁵MESEMBRYANTHEMUM *Rostratum*.

Rostrated, or Heron's bill Mesembryanthemum.] Is acaulis, or without stalks; semi-cylindric, connate leaves, having the outside set with tubercles; and yellow flowers.

²⁶MESEMBRYANTHEMUM *Corniculatum*.

Corniculated, or Horned Mesembryanthemum.] Hath a loose, creeping, succulent stalk; triquetrous semi-cylindric, horned, rough punctated, connate leaves; and yellow and orange-coloured flowers, with ten styles.

²⁷MESEMBRYANTHEMUM *Bicolorum*.

Bicolor, or Two-coloured Mesembryanthemum.] Hath a shrubby, firm, succulent stem; awl-shaped, smooth, punctated, distinct leaves; and two-coloured flowers, *i. e.* purple without and yellow within.

²⁸MESEMBRYANTHEMUM *Glaucum*.

Glaucous, or Grey-leaved Mesembryanthemum.] Hath an erect, shrubby, succulent stem; three-square, acute, punctated, distinct leaves; and yellow flowers, having the calycinal folioles oval-cordate-shaped.

²⁹MESEMBRYANTHEMUM *Ringens*.

Ringent Mesembryanthemum, or Dog's-chap Ficoides.] Is sub-acaulis, or almost without stalk; thick, three-cornered, ciliate, indented, dotted leaves; and yellow flowers.

Variety.] Cat's-chap *Mesembryanthemum*.³⁰MESEMBRYANTHEMUM *Difforme*.

Deformed-leaved Mesembryanthemum. Is acaulis; having thick, deformed, dotted, connate leaves; and yellow flowers.

³¹MESEMBRYANTHEMUM *Dolabriforme*.

Axe-leaved Mesembryanthemum.] Hath low, procumbent, succulent stalks; axe-shaped, punctated leaves; and yellow flowers, opening on nights.

³²MESEMBRYANTHEMUM *Expansum*.

Expanded Mesembryanthemum.] Hath low, loose, procumbent, succulent stalks; spear-shaped, plane, expanded, impunctated, or unspotted, distinct leaves, opposite and alternate,

nate, at a distance ; and yellow flowers, white within.

³³MESEMBRYANTHEMUM *Linguiforme*.

Tongue-leaved Mesembryanthemum.] Is acaulis, or without stalk ; tongue-shaped, tall, impunctated, smooth leaves, having very thick margins ; and large yellow flowers, with ten styles.

Varieties.] With broad leaves—with narrow leaves—long-leaved.

³⁴MESEMBRYANTHEMUM *Veruculatum*.

Veruculiforme-leaved Mesembryanthemum.] Hath a shrubby, firm, succulent stalk, three-square-cylindric, bowed, acute, unspotted, pellucid, distinct leaves, connate at the base ; and yellow flowers in clusters.

³⁵MESEMBRYANTHEMUM *Tortuosum*.

Tortuose Olive-leaved Mesembryanthemum] Hath a low, loose, procumbent, succulent stalk ; plane, oblong-oval, sub-papillose, connate leaves, in clusters ; white flowers with saffron middles, having triphyllous two-horned cups.

³⁶MESEMBRYANTHEMUM *Albidum*.

White-leaved Mesembryanthemum.] Is acaulis, having three-square, thick, firm, entire leaves, of a whitish colour ; and large golden-yellow flowers.

³⁷MESEMBRYANTHEMUM *Pugioniforme*.

Dagger-leaved Mesembryanthemum.] Hath a shrubby, succulent stalk ; awl-shaped, triquetrous, very long, spotless, alternate leaves ; and large, golden-yellow flowers, with ten styles.

All these thirty-seven species of *Mesembryanthemum*, being natives of Africa, in this country they require shelter of a green-house, &c. in winter ; they are all succulent in stalk, branch, and leaves, as before suggested. The first of which is an annual of great singularity ; all the others are perennial, and mostly durable in stem and foliage ; those described shrubby, rise with firm stems of different heights, often branchy ; the others described pendulous, have loose straggling stems and branches, inclining to the ground ; and the acaulis sorts have no stalks at all : their leaves are universally very thick, succulent, fleshy, and of so many various shapes, situations, directions, and many of them curiously punctured, or dotted, with transparent points ; others papillose, or covered with pellucid pimples, as in each respective description, that, together they exhibit a singularly agreeable variety at all times of the year, and merit a place in every curious green-house collection. They are also very ornamental in their flowers, which in different sorts appear at different seasons of the year, as in spring, summer,

autumn, and winter, and many of the sorts so floriferous as to appear covered with their flowers.

The flowers of all the species are universally monopetalous, but each is multifid or finely divided almost to the bottom, into numerous narrow segments, in several series, all uniting at the base, appearing like some sorts of marigolds, and which in their native soil, Africa, are succeeded by abundance of fruit, shaped somewhat like a fig, hence the name Fig-Marigold (*Ficoides*).

The *Mesembryanthemum Crystallinum* is a very tender annual while young ; is raised annually from seed in spring, by aid of hot-beds, until June, when it will endure the open air till October, and then perishes ; though if in autumn it is placed in a hot-house, it will often live all winter. It is commonly planted in pots, to move to different parts occasionally ; but if planted in the full ground, it grows considerably stronger, even to luxuriance ; it, however, when confined in pots, flowers the most abundantly.

All the perennial sorts are of the temperature of green-house plants, so must be kept constantly in pots to move to that conservatory in winter ; though some of the shrubby kinds are hardy enough to succeed all winter under a garden-frame, and sometimes in a warm border against a south wall ; it is, however, proper to allow the principal part the winter's shelter of a green-house.

As all the sorts are of a succulent nature, always replete with moisture, they should be potted in a poor, light, dry earth ; if sandy, or of a rubbishy nature the better ; however, any common light sandy earth, free from dung, is proper, or a compost of light dry materials. See COMPOST.

They require shelter from October till May or June, must have but little water in winter, but frequent in summer, when in the open air in dry weather.

Propagation and general Culture.

Their propagation is, the first sort by seed annually in spring in a hot-bed ; and all the others by cuttings of their stalks or branches, in summer in the common ground ; though their rooting may be facilitated by aid of artificial heat : observe the following directions for each sort.

First Species.—This sort is raised annually from seed sowed in March or beginning of April, in a hot-bed under frame and glasses, as directed for the *Amaranthus Tricolor*, *Celosia Cristata*, or Cock's-Comb, Globe *Amaranthus*,

ranthus, and other tender annuals, as one bed may raise the whole; observing to mould the hot-bed with fine rich light earth, that is perfectly dry, six inches thick; the seed may then be sowed in the earth of the bed in very shallow drills, covering it scarcely a quarter of an inch deep; or may be sowed in pots of fine mould, the same depth, plunging the pots in the earth of the hot-bed; the plants will soon rise, but they come up very weak, and advance very slowly at first, as well as being exceedingly tender, and impatient of cold and moisture in their infant growth; indulge them, however, with fresh air daily at all opportunities, as directed in the culture of the above named annuals; likewise allow them water occasionally, but use great caution in this, and always apply it as moderate and light as possible. When the plants are an inch or two high, prick out some of the strongest, either in the same hot-bed, or in a fresh one, three inches apart, or in small pots singly, giving very light waterings, and shade from the mid-day sun, till fresh-rooted; here to remain a month, or thereabouts, continuing the admission of air, as above, and support the heat of the bed; and then if they are removed with balls into pots, and placed in a new hot-bed, it will forward them greatly; at which time those intended to remain finally in pots, should be planted in proper sized ones (twenty-fours), to remain, which plunge in the hot-bed: let the whole remain in the bed under the frame and glasses. Continue the above management until the middle or latter end of June, then remove them to the full air; some to remain in the pots, others may be turned out with balls into the open borders, where they will grow freely, and spread their branches abundantly all around upon the ground, two or three feet every way.

As to future culture, those in pots must be frequently watered in dry weather; but those in the borders require no other care than to be kept clean of weeds, suffering their branches to spread about upon the ground.

To save good seed of this species, some of the potted plants should, when in full bloom, be placed either in a frame to have occasional shelter of the glasses in very wet weather and cold nights, whereby they will ripen seeds; or, if placed in a stove, or in a glass-case near the front, where they may have the free air, but defended as above, they will ripen seed more effectually; they, however, in fine dry

warm autumns, will sometimes ripen seed without the above precaution, but this is not to be depended on.

Perennial Sorts.—The propagation of all the perennial species, is effected by cuttings of the stalks and branches, any time from April till July; observing those planted before the beginning of June should generally be planted in pots, and plunged in a hot-bed, but those in June or July, succeed in the open ground.

In chusing the cuttings, observe to cut them off from about two or three to five or six inches long, according to the nature of the plants, and strength of the shoots; observing to divest them of the lower leaves, if any, and then, previous to planting, lay the cuttings in a dry airy room, for some time, to heal over the wound, or cut part, as is necessary to all succulent cuttings; some will require to lie only three or four days, others of the most succulent nature, eight or ten; for the cut part must be healed, otherwise the moisture issuing therefrom would be apt to rot the cuttings after being planted.

The cuttings being ready, then having a compost of light dry soil, either in pots or in the full ground, plant the cuttings therein, from about one inch to two or three deep, according to their length, closing the earth firmly about each, and directly give a little water; then those in pots, if early in the year, may be plunged in a hot-bed, or in the bark-bed; but if in summer, may plunge them in a dry border; observing to allow all of them occasional shade in sunny days, from about ten until three or four o'clock, till they are rooted, especially those in the open air, by a covering of mats, giving sprinklings of water in dry weather, once or twice a week; remarking that if heavy rains fall, it is proper to shield these kinds of cuttings from it as much as possible, but let them enjoy moderate showers.

In six weeks, or a little more or less time, the cuttings will be rooted, and in a growing state, when those that were struck in the full ground must be potted, those already in pots, may remain in the same; and all of them in both cases, placed in a sheltered situation till October, then removed into the green-house, or a good garden-frame furnished with glasses for the winter.

As to their general culture, it is the same as for other succulents of similar temperature; giving them shelter every winter, from October

tober until May, or beginning of June, and from thence to the end of summer place them in the open air: water them sparingly in winter, but freely in summer in dry hot weather; and shift them annually into larger pots. See GREEN-HOUSE PLANTS.

MESPILUS, Medlar.

This genus consists of deciduous fruit-trees and flowering shrubs, and a very ornamental ever-green; all hardy, of upright growth, and garnished with spear-shaped, and oblong-oval foliage, and quinquepetalous flowers; in some singly, but in the greater part in bunches, from the sides and ends of the branches; succeeded by globular, baccaceous, eatable fruit, in some sorts as large as moderate apples.

Class and order, *Icosandria Pentandria*.

Characters.] CALIX, is monophyllous, divided into five concave, patent, permanent segments. COROLLA, five roundish concave petals, inserted into the calix. STAMINA, twenty or more filaments inserted into the calix, and simple antheræ. PISTILLUM, a roundish germen below the corolla, five erect styles, and capitated stigmas. PERICARPIUM, a globular, umbilicated bacca, crowned by the connivent calix, and contains five gibbous, stoney seeds.

In this genus old botanists arranged the hawthorn, cockspur-haw, azarole, and some other species, now of the genus *Cratægus*, &c. whose flowers are also icosandrous, but have only two styles, whereas in all the proper species of *Mespilus*, now under consideration, the flowers have five styles, which is an obvious generic distinction between these two genera.

The real species, therefore, of this genus, are the following seven, six deciduous, and one ever-green, all of the tree and shrub kind.

Deciduous Kinds.

The first of these (common Medlar) is considered principally as a fruit-tree, also sometimes for variety; the others chiefly as flowering shrubs for ornament.

¹MESPILUS *Germanica*.

German Mespilus, or Common Medlar.] Rises with a deformed tree-stem, branching irregularly fifteen or twenty feet high; spear-shaped leaves, downy underneath; and large close-fitting, white flowers, singly from the sides of the branches; succeeded by large

roundish brown fruit, the size of middling apples, ripen in October, but not eatable till beginning to decay.

Varieties.] Common great German Medlar—smaller Nottingham Medlar—pear-shaped Italian Medlar.

This species and varieties are all cultivated in the English gardens for the fruit, but the German or Dutch Medlar, and the Nottingham kind, are the most common; and the latter of which two, though a smaller fruit, is rather preferable for richness and poignancy of flavour. Remarking of all these kinds of fruit, that they are never eatable until they begin to rot; for when firm and sound, are of a singularly austere disagreeable taste, yet having lain some time after being gathered, till they begin to assume a state of decay, and become soft, they acquire a delicious flavour, extremely agreeable to many, to others altogether unpalatable.

All the sorts ripen in the latter end of October, or beginning of November, when being gathered, some should be laid in moist bran, in several layers, to forward their decay, others on straw in the fruitery; those in the bran will begin to be ready for use in about a fortnight, and those laid on straw will come gradually forward in succession.

²MESPILUS *Arbutifolia*.

Arbutus-leaved Mespilus.] Mespilus with a shrubby stem, branching erectly five or six feet high; lanceolate, crenated, alternate leaves, downy underneath; and from the sides and ends of the branches, small white flowers in clusters; succeeded by small, roundish, purple fruit, like haws.

³MESPILUS *Amelanchier*.

Amelanchier, or Shrubby Medlar, with black fruit.] Rises with several shrubby, slender, hairy stems, branching moderately about four feet high, having purplish branches; oval, serrated leaves, downy underneath; and small white flowers, in clusters at the ends of the branches; succeeded by small black fruit.

⁴MESPILUS, *Chama-Mespilus*.

Chama-Mespilus, or Dwarf Medlar, commonly called Bastard Quince.] Hath a shrubby, slender, smooth stem, branching weakly four or five feet high, having purplish branches; oval, serrated, smooth leaves, on long footstalks; and from the axillas, purple flowers, collected into round heads, with narrow, purplish, deciduous bractæ; succeeded by small red fruit.

⁵Mes-

⁵MESPILUS *Cotoneaster*.

Cotoneaster, commonly called Dwarf Quince.] Rises with a shrubby, smooth stem, branching four or five feet high, the branches slender and reddish; oval entire leaves, on short foot-stalks; and from the axillas, small, close-fitting, purple flowers, two or three together; succeeded by small, roundish, bright-red fruit.

⁶MESPILUS *Canadensis*.

Canada Snowy Mespilus.] Hath a shrubby, smooth stem, branching four or five feet high, having smooth, purplish branches; oval-oblong, serrated, smooth leaves, on long foot-stalks; and all the branches terminated by clusters of snowy-white flowers; succeeded by small, purplish fruit, like haws.

*Ever-green Kind.*⁷MESPILUS *Pyracantha*.

Pyracantha, or *Ever-green Thorn*] Rises with a shrubby, spinous stem, branching diffusely twelve or fourteen feet high, the branches slender and flexible, with a dark-greenish bark, armed with long sharp spines; spear-shaped-oval, crenated, ever-green leaves; and all the shoots terminated by numerous clusters of whitish flowers; succeeded by large bunches of beautiful red berries, remaining all winter, and exhibiting a very ornamental appearance.

All these seven species of *Mespilus* are of the tree and shrub kind; the first six sorts are deciduous, the seventh an ever-green, the leaves universally simple; those of the *Mespilus Germanica* very large; the others mostly of moderate size; and which in most of the sorts grows upon short foot-stalks. They all flower abundantly every summer, the flowers universally hermaphrodite, and consist each of five large, roundish petals, twenty stamina, and five styles; and all succeeded here by plenty of fruit of the berry kind; see the *Characters*. The fruit of some is as large as middling apples, as before observed, as in the common Medlars; others scarcely the size of haws.

They are all very hardy, and succeed in any common soil and situation, and their propagation and culture is very easy.

With respect to their use in gardens, the first sort and varieties is cultivated as a fruit-tree, principally as standards, sometimes also as espaliers for variety; and are also often introduced into the shrubbery plantation to diversify the collection; all the other six species are very proper furniture for any ornamental

plantation, where they will effect variety very agreeably with their different foliage; and their flowers make a fine appearance, as also their fruit in autumn and winter, which, if not devoured by birds, remain long on the branches, and afford a fine variety in those seasons; observing to dispose the deciduous kinds in assemblage, principally with others of that tribe; and the ever-green sort also chiefly with those of its own nature; arranging each sort according to its gradation of height; but as the *Pyracantha* being remarkably ornamental, both as an ever green, and singularly beautiful in its numerous clusters of fine red berries, covering the branches in winter, it in particular should have a conspicuous situation; this sort, however, being rather of flexible growth, is most commonly trained against walls or the fronts of houses, both for the support of its flexible branches, and that it may exhibit its berries more ornamentally; it, however, may also be trained as a standard, like the other sorts, in the open shrubbery, and all of them suffered to branch out into spreading heads.

When it is designed to have any of the common Medlars as fruit-trees, they may be trained either as dwarfs, for dwarf standards, or for espaliers, or trained as half or full standards; and managed in either of these modes of training nearly as other fruit-trees, particularly the apple and pear; and are raised either by seed, by grafting, or by budding, but either of the two latter methods are the most certain for continuing the sorts without variation; observing after shortening their first shoots from the graft or bud, where it shall seem necessary, to force out a proper supply of wood to form a head; train the branches afterwards principally at full length, and let the standards branch out in their own way.

Propagation and Culture.

All the sorts are easily raised from seeds, layers, and by grafting and budding.

By Seed—By this method all the sorts may be propagated plentifully in the common ground; observing, however, that it is most eligible to raise the *Medlars* principally by grafting or budding, to continue the sorts; but in respect to sowing the seed, this should generally be sowed in autumn, in a bed of common earth: they usually lie a year, or more, before they germinate, that is, like haws and holly-berries, &c. they rarely come up before the second spring; when water them frequently in dry weather; and in autumn

tumn or spring following, the largest seedlings may be thinned out and planted in nursery-rows, two feet by one asunder; and in another year plant out all the rest in the same manner; and in three or four years, they will be proper for the garden or shrubbery.

By Layers — In autumn, or any time from that season until February or March, lay the young branches by the common method, they will be properly rooted by autumn following, when transplant them in nursery-rows like the seedlings.

By Grafting and Budding. — Either of these methods should generally be practised for raising the common Medlars, for they are apt to vary from seed; but all the other sorts may also be readily propagated by the same methods; observing, that the stocks generally used on which to work most of the sorts is the *White Thorn*, i. e. *Crataegus Oxyacantha*, raised from seed, as directed under that article; but the pear-stock is rather to be preferred for the common Medlars, when intended for fruit-trees; and the work of grafting and budding them is in the usual way, low in the stock to form dwarfs; and for half, or full standards, it may also either be performed low in the stock, and train the first shoot for a stem, or let the stock form a stem, and work them at from about three or four to five or six feet height. See GRAFTING and INOCULATION.

Observe that those intended for fruit-trees, whether dwarfs, or half or full standards, they, with respect to training, should, for dwarfs, have the first shoots from the graft or bud headed down short in spring, if necessary, to force out a proper supply of bottom-branches, which train as for other dwarf fruit-trees, either for standard-dwarfs or espaliers; or if for half or full standards, that if worked low in the stock, train the first shoot of each for a stem, then top it at the proper height, to force out laterals to form the head; but if worked high in the stock, the first shoots may either be shortened or suffered to grow as it shall seem proper, according to the natural disposition of the leading shoot, with respect to its furnishing lateral branches; remarking, after this training the first year or two, to give the tree its first proper formation, you are to desist from any general shortening of the branches, practising it only occasionally to particular shoots to procure more wood, if necessary, to fill any vacancy, or to reduce

any irregular growth, or to cut off dead parts; but otherwise train the branches principally at full length, and let the standards assume nearly their own natural way of branching. See DWARF-TREES, ESPALIERS, and STANDARD-TREES, &c.

MIMOSA, Sensitive Plant, &c.

This genus comprises shrubby and herbaceous plants, but mostly of the shrub kind, some trailing, others erect, all natives of the Indies, &c. retained here in stoves as great curiosities, particularly for the very singular sensibility of the leaves of some sorts, which on being touched, suddenly recede, contract and fall down in a very wonderful manner: all of them garnished with pinnated leaves, and monopetalous, funnel-shaped, five-parted, polygamous flowers at the axillas and ends of the branches in clusters and spikes.

Class and order, *Polygamia Monoecia*.

Characters.] CALIX, is monophyllous, small, and quinque-dentate. COROLLA, is monopetalous, funnel-shaped, and five-parted at the brim. STAMINA, many long capillary filaments, and incumbent antheræ. PISTILLUM, an oblong germen, short filiforme style, and truncated stigma. PERICARPIMUM, a long pod, having transverse partitions, containing many roundish seeds.

The name *Mimosa*, of this genus, signifies mimick, originating from the sensibility of the leaves, which by their motion mimick, or imitate, as it were, the motions of animals.

To this genus Linnæus joins many of the *Acacias*, and it comprises upwards of forty different species; though not more than a quarter of them are common in the English gardens; or that possess any particular merit either for curiosity or ornament, and none for use. Of the sorts cultivated here in our stoves, &c. some are of the shrub and tree kind, and two or three are herbaceous perennials and annuals; are mostly of the sensitive kinds, except the *Acacia* sorts, which are motionless, as expressed under their proper heads, i. e. sensitive and humble kinds, and senseless kinds. The former of which are exceedingly curious plants in the very singular circumstance of their leaves receding rapidly from the touch; for the leaves being winged, each composed of numerous small lobes, all of which on being touched, hastily run up close together; and in some sorts the foot-stalks and all is affected, so as instantly to fall downward, as if fastened by hinges.

Shrubby

Shrubby, Sensitive, and Humble Kinds.

They have all winged leaves, each wing of many small pinnæ; some only contract the lobes of the leaves and pinnæ at the touch; others not only contract every part of their leaves, but which, together with their foot-stalks, suddenly drop downward; and for distinction sake, the former are called Sensitive *Mimosas*, and the latter Humble Sensitive; but the leaves of both sorts soon recover their usual position.

¹*MIMOSA Sensitive.*

Common Sensitive Humble Plant.] Rises with an under-shrubby prickly stem, branching six or eight feet high, armed with crooked spines; conjugated, pinnated leaves, with bijugated partial lobes, or wings, having the inner ones the least, each leaf on a long foot-stalk; and at the sides and ends of the branches many purple flowers in roundish heads; succeeded by broad, flat, jointed pods, in radiated clusters.

This is somewhat of the humble-sensitive kind; the leaves, foot-stalks and all, recede from the touch, though not with such facility as in some of the following sorts.

²*MIMOSA Pudica.*

Bashful Humble Plant.] Rises with an under-shrubby, declinated, prickly stem, branching two or three feet around, armed with hairy spines; pinnated, digitated leaves, each leaf being of five or more long folioles, attached by their base to a long foot-stalk, and spread out above like the fingers of a hand; and at the sides and ends of the branches roundish heads of greenish white flowers; succeeded by small, jointed, prickly pods.

This is truly of the humble sensitive kind, for by the least touch the leaves instantly recede, contract close, and, together with the foot-stalk, quickly decline downward, as if ashamed at the approach of the hand.

³*MIMOSA Pernambuco.*

Pernambuca Slothful Mimosa.] Hath under-shrubby, procumbent, unarmed stems, branching two or three feet around; bipinnated leaves, of three or four pair of short, winged foliola; and at the axillas drooping spikes of pentandrous flowers, the lower ones castrated.

This sort receding very slowly from the touch, only contracting its pinnæ a little when smartly touched; hence the name Slothful Mimosa.

⁴*MIMOSA Asperata.*

Rough Sensitive Mimosa.] Hath a shrubby, upright, prickly, hairy, rough stem, branching four or five feet high, armed with short, broad, whitish spines; bipinnated, prickly leaves, of five or six pair of foliola, or wings, arranged opposite, having two thorns between each pair; and at the upper axillas globular heads of purple flowers; succeeded by short, flat, jointed pods, in clusters, spreading each way like a radius.

This is only moderately sensitive in its foliola, but not in the foot-stalks.

⁵*MIMOSA Punctata.*

Punctated Sensitive Mimosa.] Rises with a shrubby, upright, taper, punctated or spotted, unarmed stem, branching erectly five or six feet high; bipinnated leaves, of four or five pair of long, winged folioles, having each about twenty pair of pinnæ; and at the axillas and termination of the branches oblong spikes of yellowish decandrous flowers, the inferior ones castrated; succeeded above by oblong seed-pods.

This sort, though naturally shrubby and perennial in its native soil, yet in this country it sometimes decays in winter.

It is only sensitive in the foliola, but quick in the motion.

Herbaceous Sensitive and Humble Kinds.

Of these sorts two are perennial of the trailing kind; and one is annual, of somewhat erect growth; have all winged leaves, with the wings formed of many small pinnæ.

⁶*MIMOSA Viva.*—(Perennial.)

Lively Sensitive Mimosa.] Hath herbaceous, trailing, unarmed, repent stems, very branchy, spreading widely around, rooting at the joints as they advance; conjugated pinnated leaves, with quadrijugated, roundish, partial lobes, or wings; and at the axillas globular heads of yellowish flowers; succeeded by short, flat, jointed pods.

This species is only sensitive in the foliola, but is the most lively of that kind, it being so susceptible that all the foliola recede rapidly from the least touch, whereby it has the distinctive appellation of vivacious, or lively *Mimosa*.

⁷*MIMOSA Quadrivalvis.*—(Perennial.)

Quadrivalve Humble Mimosa.] Hath herbaceous, slender, quadrangular, prickly stems, branching and spreading all around, armed with recurved spines; bipinnated leaves of

two or three pair of winged lobes, having each many pinnæ; and at the axillas globular heads of purple flowers, succeeded by quadrivalvular pods.

This is of the humble sensitive kind, both leaves and foot-stalks recede from the touch.

⁸MIMOSA Plena—(Annual).

Double-flowered Sensitive annual Mimosa.]

Rises with an herbaceous, erect, round, unarmed stem, closely branching and spreading every way, three or four feet high; bipinnated leaves of four or five pair of winged lobes, of many pairs of pinnæ; and at the axillas and termination of the branches spikes of yellow pentandrous flowers, the lower ones double; succeeded by short, broad pods.

This annual is only sensitive in the foliola, but extremely susceptible of the touch or air.

Shrubby Insensible Kinds.

These are of the *Acacia* kind, formerly a distinct genus, but now all species of *Mimosa*; but their leaves are destitute of motion or sensibility at the touch; there are about three noted species in the English gardens, all for the stove.

⁹MIMOSA Cornigera.

Horned Mexican Mimosa, commonly called Great Horned Acacia.] Hath a shrubby, upright, deformed stem, branching irregularly, armed with very large, horned like, white spines, by pairs, connated at the base; bipinnated leaves thinly placed; and flowers growing in spikes.

This species is esteemed a curiosity for the oddity of its large spines, resembling the horns of animals, and which are often variously wreathed, twisted, and contorted.

¹⁰MIMOSA Farnesiana.

Farnesian Fragrant Acacia.] Hath a shrubby stem, branching many feet high, armed with distinct spines; bipinnated leaves, having eight pair of partial lobes, or wings; and globular, close fitting spikes of yellow sweet-scented flowers.

¹¹MIMOSA Nilotica.

Nilotic True Egyptian Acacia.] Hath an upright tree-stem, branching many feet high; armed with spreading spines; bipinnated leaves; and globular spikes of flowers, having foot-stalks. From the exudation of the leaves of this sort, is procured the drugs called *Succus Acaciæ* and Gum-arabic.

These eleven species of *Mimosa* are the most noted sorts in the English gardens; all the shrubby kinds are durable in root, stem, and branches; those of the perennial herbaceous kinds, are also often abiding; but the annual sort always perish root and branch at the approach of winter. They are all natives of the Indies, and in this country require the continual shelter of a hot-house, or of a hot-bed of similar temperature under frames and glasses; though they can hardly be supported alive in winter unless placed in a stove; so all the sorts must constantly be kept in pots, and placed principally in that department, especially during the winter; nor will they succeed well in the open air in summer, except about a month during the greatest heat; but the sensitive and humble kinds, if exposed to the open air even in the hottest days will be deprived of their sensibility during the time they remain so exposed, therefore should always be kept under glasses, in a stove if possible; or in default of such a convenience, the plants might be raised from seed in spring in any common hot-bed under frames, &c. as directed for tender annuals, and continued constantly under the glasses, and thereby will afford pleasure all summer by the oddity of their sensitive foliage; however to have them to remain in perfection the year round, some must be continued always in a stove, as before observed, for the warmer they are kept, the stronger will be their sensible quality.

The sensitive and humble kinds in particular, frequently flower in this country, and produce seeds. The *Mimosa Farnesiana* is also often very floriferous here, which are very fragrant; the flowers of all are, separately, but small, but generally grow in bunches; each flower is monopetalous and funnel-shaped, with many stamina. See the *Characters*.

The sensitive and humble plants are in great estimation among the curious for the singular sensibility lodged in their leaves; which has two kinds of motion, the one occasioned by the action of warm nourishing vapours; the other artificial, in consequence of being touched or shaken; that with whatever body it is touched or irritated, either by the hand, a stick, or the least wind blowing, the wings of the leaves suddenly close, and the foot-stalks fall down; but they all soon recover their proper position, especially in a warm stove.

It is remarkable, the sensibility of some reside particularly in the articulation or joinings of the lobes of the leaves to the partial foot-stalks, as in the simple sensitive; in others both in the joinings of the lobes, and in the articulations of the mid-rib, to which they are attached, as also to the main or common foot stalk, as in the humble sensitive kind.

The motion of these plants is owing to a strong contraction; each foot-stalk seems to terminate with a kind of joint, on which the lobes and leaves turn in all directions with surprising facility, and the main foot-stalk seems attached to the branches by a joint, so as to turn up and down as by a hinge.

In the experiments of trying the sensibility of these plants, that in touching the upper leaves, if in contracting they fall and touch those below them, those will also all contract and fall, so that as one touch another they will continue falling one after another for a considerable time in a curious manner.

The time which the leaves, &c. require to recover themselves, after falling by any touch or irritation, is according to the vigour of the plant, hour of the day, serenity of the atmosphere, and temperature of the heat of the stove, &c. so are often from about ten or fifteen minutes to an hour or more, before they are fully reinstated in their former proper positions.

It is remarkable that the plants each evening naturally contract themselves, and expand again in the morning.

Propagation and Culture of all the Sorts.

The propagation of all the sorts both sensitive and *Acacias*, is by seed in spring in a hot-bed, or in the bark-bed in the stove; and some of the sensitive kinds also by layers and cuttings.

By Seed.—It is sold at the nurseries and seed-shops. Sow it in pots of light rich mould, covering it with fine earth a quarter of an inch deep, and plunge the pots in the hot-bed, if in a common hot-bed under frames and glasses; manage them nearly as directed for tender annuals, such as the *Amaranthus Tricolor*, and others of that quality; and if in a bark-bed in the stove, very little trouble is required: observing to give moderate sprinklings of water, and when the plants are two or three inches high, prick them singly in small pots, which plunge also in the hot-bed, &c. giving water and occasional shade till rooted, repeating the waterings frequently, and continue the plants in the hot-bed under

glasses, or plunged in the bark-bed of the stove, being both necessary to facilitate their growth, preserve them in vigour, and encrease the sensibility of the sensitive kind; allowing air in common with the other plants in the bed. Remarking, that to preserve the perennial sorts, both shrubby and herbaceous, they must be kept in the stove all winter, and indeed principally the year round, when they will be of several years duration, flower in summer, and ripen seeds in autumn, particularly some of the sensitive kinds.

But in want of a stove, as before hinted, those who are curious to have some sensitive plants, may nevertheless have the pleasure of them in summer, by aid of a common dung hot-bed under frames and glasses, but not in winter; that is, raise some plants, either of the annual sort or any of the other kinds, by seed in spring, in a hot-bed under a frame, &c. as above directed, keeping up the heat of the bed until the middle of June, and continue the plants always under the frame, tilting one end of the lights a little, occasionally in warm days to admit fresh air; and as the plants rise in height raise the frame at bottom, to allow them full room to grow; or about Midsummer, or soon after, some of the low spreading kinds may be turned out with balls, or plunged in their pots into a warm sunny border, and covered with large hand-glasses, which may be lifted off occasionally just to view the plants. By those methods the plants may be preserved through the summer in their sensitive quality, tho' not equal in perfection to those in stoves; nor can they be preserved alive in winter out of a stove.

By Layers.—Any of the shrubby kinds that afford spreading branches may be layed any time in summer, in pots plunged contiguous in the bark-bed, where they will readily take root, and be ready to pot off singly in autumn.

By Cuttings.—The sensitive and humble kinds often branch out profusely, so as to furnish plenty of young shoots in summer, of which take cuttings, plant them in pots, and plunge them in the bark-bed, they will readily take root and form proper plants.

But after all, seedlings generally form the best plants; however, any of the other two methods is eligible in default of seed.

With respect to the general culture of all the species, they must always be kept in pots; and to preserve them all the year, must be placed in the stove, plunged chiefly in the

bark-bed, giving frequent watering both in summer and winter, but most in the summer season; shifting them into larger pots as they encrease in growth: observing, that although most of the sorts will live in the open air about a month or so in the heat of summer, it will be best to expose them but sparingly, rather place them in an airy glass-case for a month or two in the summer, moving them to the stove again in due time.

MIRABILIS, Marvel of Peru, or Four-o'clock-flower.

This genus consists of three large-growing bushy, very floriferous perennials, from Peru in South America, admirably ornamental for the pleasure-ground in summer, but which, although naturally perennial, often prove annual here: all of them, however, rising with annual stalks, three or four feet high, branching widely all around; closely ornamented with large, oblong, entire leaves; and numerous, beautiful, monopetalous, funnel-shaped flowers, of beautiful colours.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, is pentaphyllous, erect, ventricose, the leaves oval and persistent. COROLLA, is monopetalous and funnel-shaped, having a long slender tube resting on the nectarium; the limb or upper part erectly spreading, plaited, and obtusely quinquefid, and with a globose nectarium under the corolla. STAMINA, five slender, unequal, inclined filaments, and roundish antheræ. PISTILLUM, a roundish germen within the nectarium, slender style, and globular stigma. PERICARPIUM, none, the seed is an oval pentagonous nut.

There are but three species, all of which are natives of Peru, in the Spanish West Indies, and in this country are tender, generally requiring to be forwarded in spring in a hot-bed until June.

The species are:

¹MIRABILIS *Jalap*.

Jalap Mirabilis, or Common Marvel of Peru.] Hath a large, thick, fleshy root; an upright, thick, jointed stalk, dividing and branching numerously, widely, and erectly, a yard or more high; garnished with oblong, broad, opposite leaves; and all the branches and shoots terminated by numerous flowers in clusters, of different colours in the varieties.

Varieties.] With white flowers—with yellow flowers—with purple flowers—with red flowers—with white and yellow flowers—

white and purple flowers—purple and yellow flowers—red and yellow flowers.

Several other varieties often rise from seed; and it is remarkable that although several of the above colours and variegations are sometimes common to the same plant, yet it is rare that a plant of this species produce flowers of one of those colours alone; sometimes, however, the same plant will exhibit only white and purple flowers separate, and sometimes both colours in the same flowers, intermixed with the plain ones; the same is also observable in the red and yellow; others have plain flowers of several different colours; and sometimes variegated flowers also on the same plant.

The root of this species was supposed to be the true officinal jalap, but which is since discovered to be the root of a species of *Convolvulus*.

²MIRABILIS *Longiflora*.

Long-flowered Mirabilis.] Hath a large, thick, fleshy root; a thick stalk, dividing low into many declinated spreading branches, extending two or three feet every way; large, heart-formed, hairy, viscous leaves, in opposite pairs; and all the branches and shoots terminated by white flowers in clusters, having very long tubes, nodding downward.

³MIRABILIS *Dichotoma*.

Dichotomous, or Forked Mirabilis.] Hath a thick fleshy root; an upright, thick, swollen, jointed stem, branching forkedly, two or three feet high; oblong opposite leaves; and smallish red flowers at the axillas, singly and close fitting.

All these plants flower in July, continuing in plentiful succession until October, very conspicuous and elegant. Having the singularity of being shut all day, and expand towards the evening when the sun declines; hence the inhabitants of the Indies, where they grow naturally, called them Four-o'clock-flowers: their time of opening here, however, depends on the weather, for if cloudy, or that the sun is not very vehement, they often open great part of the day.

The flowers are universally hermaphrodite, and of one funnel-shaped tubular petal, having the lower part a long narrow tube, and the upper spreading. See the *Characters*.

These plants are naturally perennial in root, which, however, if not preserved here in winter, prove but of one year's duration, but if sheltered from frost and wet during the winter season, they will remain alive, and shoot.

shoot out strongly again in spring: in this country, however, the plants are commonly considered as annuals; because they rising from seed in the spring, and the same year produce flowers and perfect seed; and if left to nature in the open air, totally perish in winter, at the first attack of frost or excessive wet; but, as aforesaid, if in autumn when the stalks begin to assume a state of decay, the roots are taken up, and preserved in sand in a dry room all winter, and planted again in spring, they shoot out afresh stronger than at first, and sometimes obtain four or five feet stature, with very spreading heads; or if plants growing in pots, having the stems cut down in autumn, and the pots placed in a green-house, or garden-frames under glasses, the roots may also be preserved sound, and will shoot out again in spring as above.

The roots generally become large, tuberous and fleshy, covered with a dark rind.

All the species are of a tender nature, scarcely able to endure the open air here fully day and night, until May or June; that is, they being raised from seed in spring, chiefly in hot-beds under glasses, continued and forwarded there until the beginning of June, then fully exposed in the borders or pots, they become large branchy plants in July and August, and continue flowering until October or November, till prevented by the cold.

They are all elegant furniture for the principal compartments of the pleasure ground, they being both very ornamental in their large branchy growth, closely garnished with leaves, and by flowering so numerously seem as if entirely covered with flowers, in constant plentiful succession from July till the beginning of winter, as aforesaid.

The roots of all these plants is a strong purgative, and given in a double quantity operate equal to the true jalap.

Their Propagation and Culture.

The propagation of all the species is by seed in the spring, either in a warm border, or in a hot-bed; but the latter will forward the plants to considerably the earliest and greatest degree of perfection.

First, by raising them in warm Borders.—Remark, we only recommend this in default of the convenience of hot-beds; and April is the proper season for this mode of sowing these sorts: chuse a warm south border, open to the sun; there sow the seed in shallow drills, half an inch deep, and six inches asunder: if

the place is covered with hand-glasses, or with a frame and lights, or any other occasional shelter on nights and cold weather, it will forward the germination of the seed, and growth of the young plants: in June they will be fit to transplant into the borders or in pots, chuse moist weather, and give water and occasional shade till rooted, they will then readily grow and acquire a tolerable size; but these will hardly attain a large size so soon, nor flower so early by a month or six weeks, as those brought forward in a hot-bed.

By Hot-beds.—By sowing and forwarding in hot-beds, under frames and glasses, is the only method by which we can obtain Marvel of Peru in due perfection in the proper season: therefore in March prepare a hot-bed under frame and lights, as directed for tender annuals, such as balsamine, &c. and earth it all over about six inches deep; sow the seed in the earth of the bed, in shallow drills half an inch deep, as aforesaid, or in pots of rich earth the same depth, plunging them in the earth of the bed. The plants will soon rise; indulge them with fresh air daily, in common with other plants of the bed, by tilting the glasses, and give frequent refreshments of water. When they are near two inches high, prick them into another fresh hot-bed to forward them, placing them either in the earth of the bed, four or five inches asunder, or plant them singly in small pots (thirty-twos), and plunge them in the bed: as soon as planted give water, and shade them from the mid-day sun occasionally till fresh-rooted, continuing the care of admitting fresh air every mild day; and towards the middle or latter end of May, when they have acquired some size and strength, begin to inure them by degrees to the full air, so as by the first or second week in June they may be removed into it fully, at which time chuse mild cloudy weather, if showery the better; take up those growing in the bed, with balls of earth about their roots, and plant them in the borders; or if in pots, they may be readily turned out with the whole ball entire, and planted without their ever shrinking or feeling their removal; some may also be planted in large pots to remain in order for moving to ornament any particular compartment: observing to give water directly, and bestow occasional shade to such as shall require it, together with a repetition of waterings to the whole, till they have struck fresh root and begin to grow: after this they will not require any farther culture, except occasional

sional support of stakes, which will be more particularly necessary in the *Mirabilis Longiflora*.

They will mostly begin flowering in July, and will furnish plenty of ripe seed in autumn for the purpose of propagation another year.

But as we before suggested, that if the roots are taken up in autumn, i. e. October, or early in November, dried, cleaned, and laid in dry sand, in any dry room, secure from frost and wet, they will remain sound; and in spring, if planted in large pots, and in March or April plunged in a hot-bed under a deep frame, they will shoot out remarkably strong, sometimes four or five feet high, flower earlier by a month than seedlings of the same year.

Or such of the plants as grow in pots, that having their stems cut down in October or November, may be placed in their said pots in a green-house, near the windows, all winter, kept from wet, the roots will remain sound, and in spring treat them as above.

MOMORDICA, Male Balsam Apple.

The plants are herbaceous trailers, of which there is a hardy perennial, cultivated both for variety and medical use, having long trailing stalks, garnished with broad simple leaves, and monopetalous monoecious flowers.

Class and order, *Monoecia Syngenesia*.

Characters.] CALIX, male and female flowers apart on the same plant, having monophyllous, concave, five-parted cups, and those of the females are placed on the germen. COROLLA, is monopetalous, large, rough, spreading, and adheres to the calix. STAMINA, three awl-shaped filaments in the males, with eared antheræ, two of them bifid, one single. PISTILLUM, a large germen under the corolla, taper trifid style, and three oblong gibbous stigma. PERICARPIUM, an oblong-oval trilocular fruit, opening with elastic force, filled with many compressed seeds.

There are several annual species of but little merit; but the sort commonly cultivated is the following perennial.

MOMORDICA *Elaterium*.

Elaterium, or Wild Spurting Cucumbers.]

Hath thick, fleshy, spreading roots; many trailing, angular, rough stalks, branchy and spreading two or three feet all around; garnished with large, angular, heart-formed, rough, grey leaves, on long rough foot stalks; and at the axillas small, monoecious, yellow flowers; succeeded in the females by oval, cucumber-like, hispid fruit, that dart out their seeds with great velocity.

This species is one of the *Noli me tangere*, or Touch-me-not kinds, for upon handling the ripe fruit, it instantly bursts with elastic violence, and discharge its juice and seeds with amazing force all around to a great distance, often causing consternation to strangers who happen to touch them.

This plant is very hardy, and grows freely from seed in the common ground, and is of several years duration.

The fruit affords the officinal elaterium for medicine.

The propagation of this plant is by seed in autumn or spring, in a bed of common earth, sowed either by broad-cast and raked in, or in drills half an inch deep; and when the plants have leaves two inches broad, transplant them, those intended for use in rows three or four feet asunder; and may also disperse some in the pleasure-ground for variety: give occasional watering till fresh-rooted.

From the self-sowed or scattered seeds, many young plants often rise spontaneously.

MONADELPHIA, the name of the sixteenth class of the Linnæan system, consisting of plants with hermaphrodite flowers, having all the stamina monadelphous or united into one body, with the style passing through them: examples of monadelphous plants are hollyhock, lavatera, marsh-mallow, &c. and consists of five orders, arising from the number of styles (five). See CLASSIS.

MONANDRIA, the name of the first class in the Linnæan system: consisting of plants with hermaphrodite flowers, having but one stamina. Examples of Monandrous plants are Indian arrow-root, blite, &c. and consists of two orders, derived from the number of styles (two). See CLASSIS.

MONARDA, (*Monarda*) Lion's Tail.

It consists of herbaceous, fibrous-rooted, floriferous perennials and biennials, of upright growth for the pleasure-ground, rising with angulated erect stems, two or three feet high, adorned with oblong simple leaves, and terminated by large heads of monopetalous ringent flowers.

Class and order, *Diandria Monogynia*.

Characters.] CALIX, is monophyllous, tubulous, cylindric, channelled, five-parted at top, and permanent. COROLLA, is monopetalous, with a cylindric tube, ringent above, divided into two lips, the upper one narrow and entire, and the under broad, reflexed, and three-parted. STAMINA, two bristly filaments involved in the upper lip, and

and compressed erect antheræ. **PISTILLUM**, a quadrifid germen, filiforme style, involved with the stamina, and acute bifid stigma. **PERICARPIUM**, none, four naked seeds lodged in the calix.

There are about three species cultivated in our gardens; are all North American plants, and hardy enough to succeed here in the open ground; proper for ornamenting the pleasure-ground as flowery plants.

The principal species are;

¹**MONARDA Fistulosa**.—(Perennial).

Fistulous Canada Monarda.] Hath a fibrey, strong, spreading root; upright, obtuse-angular, hairy stems, rising a yard high, branching out at top; oblong, broad-based, pointed, hairy, opposite leaves, on long foot-stalks; and all the stalks and branches terminated by large heads of fistulous purple flowers.

²**MONARDA Didyma**.—(Perennial).

Didynamus Pensylvanian Scarlet Monarda, or Oswego Tea.] Hath a creeping root; upright, acute-angular stems, rising two feet high; oval-lanceolate, smooth, opposite leaves, on short foot-stalks; and the branches terminated by large heads of bright-red flowers, sometimes having didynamous stamina.

The leaves of this species are remarkably odoriferous, and in North America are sometimes used for tea.

³**MONARDA Punctata**.—(Biennial).

Punctated Virginian Monarda.] Hath fibrey roots; upright square stalks, branching quite from the bottom to top, about two feet high; spear-shaped, serrated leaves, of different sizes in clusters at each joint; and large verticillate, yellow flowers, having the corolla punctated or dotted with purple.

All these plants flower here abundantly in July, make a very ornamental appearance; succeeded by ripe seed in autumn, by which all the sorts may be raised; the perennial sorts also by roots and cuttings. See the *Propagation*.

The flowers are universally hermaphrodite, monopetalous, and ringent, numerous and collected into heads, each having a leafy involucre.

All the three species are very hardy, the first and second are perennials, the other is biennial, and sometimes annual, if raised early in spring. They all succeed in any open compartment, and are proper furniture for the embellishment of the pleasure-ground, in the elegance of their flowers, which are very

conspicuous, continuing long in full beauty, and are all fine aromatics.

The propagation of all the sorts is by seed; the perennials also by parting the roots, and by slips and cuttings.

By Seed.—Sow it in autumn, or early in spring, in a bed of good earth, and rake it in: the plants will soon rise, and be fit to prick out in June, in nursery rows half a foot asunder, giving water, and let them remain till October or November, then transplant them where they are to flower.

By planting the Roots.—Autumn or early in the spring is the proper time, when, of the two perennial sorts, divide or slip the roots into sets; almost every bit will readily grow, planting them either in a nursery for a year, or, if strong, at once where they are to remain, and each will flower next summer.

By Slips, &c.—In May or June take off some robust slips or cuttings of the branches, five or six inches long, plant them in a shady border, giving occasional waterings, and they will readily grow, and form good plants by autumn.

MONOECIA, the name of the twenty-first class in the Linnæan system, consisting of plants with male and female flowers, separated on different parts of the same plant. Examples of monoecious plants, are cucumber, melon, gourd, &c. and consists of eleven orders, from the number of styles (eleven). See **CLASSIS**.

MONOPETALA, Monopetalous, of one petal; applicable to flowers only; and a corolla formed of one leaf, or petal, is termed Monopetalous. A Monopetalous corolla is sometimes wholly entire, without any division; sometimes is cut into two parts, *bifidum*; in three, *trifidum*, or *tripartite*; in four, *quadrifidum*; in five, *quinqesfidum*; in many, *multifidum*, &c. See **COROLLA**.

MONOPHYLLA, Monophyllous, or one leaved, applicable most commonly to the calix of flowers; for a calix of one leaf only, is termed Monophyllous, and which sometimes consists of one entire piece without divisions, *integerrimum*; sometimes cut into two, *bifidum*; some into three, *trifidum*; in four, *quadrifidum*; in five, *quinqesfidum*; in many, *multifidum*, or *multipartite*. See **CALIX** and **PERIANTHIUM**.

MORUS, Mulberry-tree.

This genus is wholly of the tree kind, and mostly deciduous; consisting of about six or seven species, four of them hardy for the open ground;

ground; some of which as fruit-trees, and some for variety; and two are tender exotics, rarely cultivated here: all of them adorned with large, heart-shaped, oval, and oblong, rough leaves; and monoecious apetalous flowers, the males in amentums, and the females in round heads, formed of the succulent calixes, which become the fruit.

Class and order, *Monoecia Tetrandria*.

Characters.] CALIX, monoecious flowers, the males collected into amentums, having cups divided into four oval concave parts; and the females into round clusters, having cups composed of four roundish, succulent, permanent leaves. COROLLA, none. STAMINA, in the males, four subulate filaments, and simple antheræ. PISTILLUM, in the females a cordate germen, two subulate, long, reflexed styles, and simple stigmas. PERICARPIUM, none, the female calixes become large, fleshy, succulent berries, full of tubercles, each tubercle having an oval acute seed.

The most remarkable species of this noted genus are the four following, all of hardy growth; the first of which is the common Mulberry of our gardens.

¹MORUS *Nigra*.

Common Black-fruited Mulberry-tree.] Rises with an upright, large, rough trunk, dividing into a large, branchy, very spreading head, rising twenty feet high or more; large, heart-shaped, rough leaves; and monoecious flowers; succeeded in the females by large, succulent, black berries.

Variety.] With jagged leaves and smaller fruit.

This species is the proper Mulberry-tree for general cultivation in this country for its fruit; the tree being a plentiful bearer, and the fruit ripen in good perfection in August and September.

²MORUS *Alba*.

White Mulberry-tree.] Rises with an upright trunk, branching twenty or thirty feet high; garnished with large, oblique, heart-shaped, smooth, light-green, shining leaves; and monoecious flowers; succeeded by pale-whitish fruit.

Variety.] With purplish fruit.

³MORUS *Papyrifera*.

Paper Mulberry-tree of Japan.] Grows twenty or thirty feet high; with large palmated leaves, some trilobate, others quinquelobed; and monoecious flowers, succeeded by small black fruit.

In the countries where this tree grows naturally, the inhabitants make paper of the bark.

⁴MORUS *Rabra*.

Red Virginia Mulberry.] Grows thirty feet high; with very large, heart-shaped, rough leaves, hairy underneath; and monoecious flowers, succeeded by large, reddish berries.

All these trees are very hardy, succeed in any common soil and situation. The *Morus Nigra*, Black Mulberry, is the only sort proper to cultivate as a fruit-tree for its fruit, the others are principally employed here to form variety in our ornamental plantations, of which the White and Paper Mulberry, are the most common, the red sort being very scarce in the English gardens; the black, and the white-fruited kinds, are also eminent for their leaves to feed silk-worms, they being the principal food of these valuable insects; but the White Mulberry leaves are in the most esteem for this purpose; and abroad, in France and Italy, &c. vast plantations of the trees are made solely for their leaves to feed silk-worms, which amply reward the possessors with the annual supply of silk they spin from their bowels: plantations of the same trees has formerly been recommended in this country for the purpose of silk-worms, to introduce the manufacturing of raw silk, since it is observable that where the trees thrive, the silk-worms will also prosper: all recommendations, however, have proved fruitless, although it in time might probably turn to a national advantage.

The leaves of these trees are generally late before they begin to come out, the buds seldom beginning to open till the middle or towards the latter end of May, according to the temperature of the season; and when these trees in particular begin to expand their foliage, it is a good sign of the near approach of fine warm settled weather: the white Mulberry, however, is generally forwarder in leafing than the black.

The flowers and fruit come out soon after the leaves; the males in amentums, as before hinted, and the females in small roundish heads; neither of which are very conspicuous, nor possess any beauty, but for observation; the female or fruitful flowers always rise on the extremity of the young shoots, on short spurs; and with this singularity, the calixes of the flowers become the fruit, which is of the berry kind, and being composed of many tubercles,

tuberances, each of these furnish one seed. See *Characters*. The fruit ripens here gradually from about the middle of August until the middle of September; which in dry warm seasons ripen in great perfection, but when it proves very wet weather, they ripen but indifferently, and prove devoid of flavour.

Considered as fruit trees, the black-fruited kind is the only proper sort to cultivate, the trees being not only the most plentiful bearers in this country, as before noticed, but the fruit are larger, and much finer flavoured than the white kind, which is the only sort, besides the Black Mulberry, that bear fruit in England.

The Black Mulberry, therefore, as a fruit-tree, may be trained either as a standard, half-standard, dwarf-standard, and as wall-trees and espaliers. Standards is the most common mode of cultivating them, in gardens and orchards, and in which they bear very abundantly; but in large gardens, where there is scope to work upon, a few trees may be also trained in each of the other above methods: they will effect the greater variety; and those against walls and espaliers will generally have larger fruit, ripen sooner with an improved flavour; and which will be succeeded by those upon the standards: remark, however, to allot a sufficiency of standards to furnish the principal crop of fruit, which, if for private use, half a dozen trees may be sufficient, though I have known one large tree furnish more Mulberries than was necessary for the supply of a great family.

The trees may be planted either in the kitchen-garden, orchard, or pleasure-ground, allowing them a dry situation and sunny exposure, both of which being requisite to promote the early ripening of the fruit, and give it due flavour; standard Mulberries are often disposed singly on grass ground, in which when grown up into spreading heads, they have a fine effect, and their fruit may be always readily gathered; though when growing on cultivated ground, it is probable the fruit may be larger; the standards should stand twenty or thirty feet asunder at least, to give full scope to their spreading heads; and the dwarfs, for walls and espaliers, fifteen or twenty feet distance from one another; remarking, that in all the above modes of training, not to practise any general shortening of the shoots, but, except on particular occasions, leave them mostly at full length; for as

the fruit is produced near the ends of the young wood, shortening would be cutting off the parts designed by nature to yield the fruit. See their *Propagation*, &c.

Mulberry-trees rarely bear any considerable quantity of fruit till they are many years old; and old trees are always not only the most fruitful, but the fruit larger and of a richer flavour.

Ripe Mulberries are an agreeable sweet fruit, of a refreshing relish, and fine cooling quality, and therefore excellent for the desert; also proper for some culinary uses, as for tarts, &c. and the syrup of Mulberries is well known.

The bark of the root of these trees being a fine bitter astringent, is admirable for killing worms in the human body.

Propagation of all the Sorts.

The propagation of all the sorts is by seed, by layers, and by cuttings; also by grafting and inoculation.

By Seed.—All the sorts may be raised in amazing plenty from seeds in the open ground, but remarking, that when they are designed principally as fruit-trees, I would not recommend this practice, because the seedling-trees are apt to vary, and out of numbers so raised, there may be but few good sorts, or that prove good bearers; therefore for fruit-trees, layers, cuttings, grafting, &c. are the only certain methods to continue the approved sorts. By seed, however, is eligible enough where large quantities are required for barren plantations, or for shrubberies, &c. it is generally procured from France or Italy; and March is the proper time of the year of sowing them, which may be either in a warm border, or in a moderate hot-bed, earthed half a foot deep, and arched with hoops to be matted in nights and cold weather. Sow the seeds in shallow drills near half an inch deep: give refreshments of water occasionally, and when the plants appear, mat them in cold nights and morning frosts, repeating the waterings all summer in dry weather; and in winter continue the occasional shelter of mats when frosts approach. And after having two years growth in the seed-bed, plant them out in nursery-rows two feet asunder, and half a yard apart in the lines: here let them remain a few years, training them for their several purposes, as above mentioned, the principal part for standards, with single stems, six feet high; others for half-standards; and a few for dwarfs, heading down the

the dwarfs, while young, near the ground, to force out branches near the bottom, to train either for dwarf-standards, or for walls or espaliers.

But the following are the only methods of propagation by which we can with certainty continue the approved sorts; in all of which methods always, if possible, propagate from trees remarkable for bearing large fruit, and plentiful crops.

By Layers.—Where great quantities are required, some trees should be planted for stools, having the heads taken off near the ground to force out plenty of bottom-shoots near the earth for laying; for the branches of the full-grown trees are often so far from the ground, that they cannot be brought down low enough to be layed; in this case, however, where only a few are wanted, some large pots, boxes, or baskets of mould may be elevated upon stands near the branches proper for laying. In either method lay the shoots by slit-laying, heading them to one eye above the surface; thus they will readily take good root, sufficient for transplanting by autumn following, in nursery-rows: as for the seedlings, train them in the same manner.

By Cuttings.—October and November is the proper season; chuse young shoots of the former summer, from healthful good-bearing trees, cutting them off from about eight or ten to fifteen inches long, plant them in a shady well-sheltered place, in rows, setting them two thirds at least in the ground; many of them will be properly rooted next autumn. But the most expeditious method is to give them the aid of a hot-bed; in March, therefore, plant a parcel of middling cuttings in pots of earth, and plunge them in any moderate hot-bed, it will greatly facilitate their rooting; being careful to harden them by degrees to the full air; give occasional shelter in the following winter, and in spring plant them out in the nursery-way, treating them as above directed.

By Grafting and Budding.—This is rarely practised, since they grow so freely by layers and cuttings; grafting and budding, however, are also certain methods for continuing the proper sorts; and when intended for practice, it must be performed on seedlings of any of the species, in the usual method.

Culture as Fruit-trees.

As before observed, they as fruit-trees may be trained both as standards in the open-ground, and as dwarfs for walls and espaliers,

As Standards.—They may be both full standards, half-standards, and dwarf-standards, but principally as full or half-standards. To have them full-standards, train them with a single, upright, clean stem, six feet high at least, then top them to branch out laterally at that height to form a head. Half standards train with four or five feet stems, then let them branch into heads. Dwarf-standards may have half a yard or two-foot stems, at which height encourage branches all around for a head, (see STANDARD-TREES, DWARF-TREES, &c.) observing to assist the whole a little at first, when necessary, in forming their heads somewhat regular, by pruning irregular growths, as directed for other standard and dwarf fruit-trees. In either of these forms they may be planted out in the garden or orchard; where let them principally take their own natural growth, giving no other pruning than regulating or retrenching any cross-disposed, or other irregular branches, or thinning where much too close. Never shorten the shoots, unless their ends are dead; for the fruit-spurs always arise towards the extreme part of the young wood, as already observed.

Thus will all these kinds of standard Mulberries gradually form themselves into a bearing state, though they rarely begin to bear any great quantity till twelve or fifteen years old.

As Dwarfs for Walls, &c.—Although the fruit ripen very well upon standards, yet when trained against walls and espaliers, the size and flavour is often considerably improved; therefore it is proper to have a few trees trained in both these ways, i. e. walls and espaliers, for variety: one mode of culture often serves both. They are at first to be headed down low in the nursery, to procure branches near the ground, as directed under the article DWARF-TREES, &c. then, being thus furnished with some lower branches, plant them against a south-wall, or in espaliers, fifteen feet asunder; where train their branches along horizontally, regularly to the right and left, six inches asunder, each at full length, for the reason already given, unless where shortening is necessary to obtain a supply of wood to fill the allotted space; which should be regularly covered with bearing-branches quite from bottom to top of the wall or espalier, at the above distance from one another; observing each year in summer and winter pruning, to cut out all superfluous and irregular shoots; at the same time train in different

rent places of each tree some regular lateral shoots, both towards the lower and upper parts, to be coming forward to a bearing state, that every part of the tree may be filled with bearing shoots, advancing one after another, and as the foremost shoots become too long, and require cutting off, the laterals will one after another, as just observed, be ready to supply their places; and likewise of such parts as become cankered or dead.

When these trees are required for plantations for variety, they should be trained up either to full stems, six feet high at least, and then suffered to branch out in their natural way, or may be trained as half-standards for smaller shrubberies, or even some as dwarfs, to cause a greater variety.

MOTUS, Motion. The term Motion, applied to plants, is expressive of the direction of growth in different parts of plants.

The direction of the Motion of the roots and stems is totally opposite; the former either running directly downward into the ground, or horizontally under the surface; and the stems direct their Motion towards the air and light of the sun, mostly in an upright position; but many run horizontally along the surface of the earth.

The causes which concur in promoting the Motions of plants, are the moist and warm vapours of the earth to the root, and the air and light of the sun to the stem; for place any number of plants growing in pots, in a room which only admits a small portion of light at one place, the stems will all incline towards that side; in close dark thickets the young trees always lean to the part where the most light penetrates; and the new shoots of an espalier, or wall-tree, detach themselves from the espalier or wall, in quest of the free air and light.

The force of Motion seems to be greater in roots than in stems; the root without ever once going out of its way pierces the hardest soils, penetrates into walls, which it overturns, and even into rocks, which it splits; whereas stems and branches surmount an obstacle, by leaving their natural direction, and over-topping it.

Although the natural direction of most stems or trunks be to ascend, as was before observed, yet some by their weakness, or natural tendency descend, and sometimes by means of roots breaking out all along the stems and branches, as in strawberry, penny-royal, and many other repent plants, such

stems are by these roots striking into the earth, tethered as it were to the ground, and only their extremities can direct their course upwards.

Leaves and flowers also direct their course towards the air, and light of the sun; leaves always turn their upper surface outward to the air and light; very obvious in wall-trees, and that if a branch is over-turned, so that the leaves are turned the contrary way; they will all naturally direct their surfaces again gradually upward to the light and air, tho' this often costs them several days growth; many flowers also present their surface directly to the sun, and follow the diurnal course of that luminous body, such as the sun-flower, and most of the compound flowers; in all of which the disk or surface looks towards the east in the morning, the south at noon, and the west at night.

During the heat of the sun the pinnated or winged leaves, particularly of the papilionaceous tribe, rise vertically upward; the opposite lobes or folioles, which compose these leaves, rise so as they are generally applied close together by their upper surfaces; but in that state of the atmosphere which generally precedes a storm, or during a close moist cloudy air, the lobes of the same sort of leaves extend themselves commonly along the foot-stalk; and after sun-set they incline still lower, and hang vertically down under the foot-stalk, and are applied close together like the leaves of a book, by their lower surfaces; this Linnæus calls the sleep of plants.

Many simple leaves, when the surface is exposed to an ardent sun, become concave above, but gradually recover as the heat declines.

But of all the Motions of leaves, none is so sudden and rapid as that of the sensitive and humble plants. See **MIMOSA**.

Another kind of Motion in plants is elasticity, which is resident particularly in some sorts of seed-vessels, such as the yellow balsamine, and spurting cucumber, &c. in which their fruit, when arrived at maturity, burst open like a spring, and dart out their seeds also with elastic force to a considerable distance.

MOULD, or Earth. See **EARTH**.

MULCH, a sort of strawey dung, somewhat moist, and not rotted, and is useful in gardening, to protect the roots of new-planted choice trees or shrubs from severe frost in winter; and from being dried by the fierce sun or drying

drying winds in spring and summer, before they are well rooted; for both of which purposes, it is spread evenly on the surface of the ground round the stem of the tree, as far as the roots extend, about three or four inches thick; but which may be augmented in winter if the severity of the frost render it necessary.

MULTICAPSULARE, Multicapular, or many capsules; plants whose seed-vessel is formed of several capsules united in one as it were, such as those of columbine, peony, aconite, larkspur, and the like. See **CAPSULA**.

MULTIFIDUS, Multifid, many parts, a flower, or calix of a flower that is divided into many segments; the term is also applicable to leaves. See **FOLIA**.

MULTIFLOROUS, many flowers on one foot-stalk; or,

MULTIPLICATUS *Flos*, a Multiplied Flower; one whose petals are multiplied in number beyond their natural, or characteristic, or single state, in two, three, or more series; and such kinds are commonly called double flowers.

All Multiplied Flowers, however, are unnatural productions, because the singles of every genus are the original, and the doubles are accidentally produced from the seeds of the singles; for a corolla in its single state, whether of one or several petals, is that proper from which to draw the characters of any genus; never from doubles, which being only varieties, are not to be depended on; so that among botanists, double flowers are often termed vegetable monsters, and are disregarded; but, on the other hand, double flowers are often the florist's pride.

But a double flower is properly that whose petal or petals are twice repeated, though in the common acceptation of the word *double*, all flowers whether the petals are twice, thrice, or many times repeated in several series, are among florists generally called by the general name of double flowers; in some the petals are often so multiplied as to obliterate the parts of fructification, in which state they come under the denomination of luxuriant. See **LUXURIANT FLOWERS**.

Multiplication is less common in flowers naturally of one petal, than those with several; in the former, however, it frequently happens, as in *campanula*, &c. though not full in the highest luxuriance; but in the latter are subject to all degrees of luxuriance from the lowest to the highest, exemplified in *anemone*, *ranunculus*, *marsh-marigold*, &c. See **PLENUS Flos**.

MUSA, Plantain-tree, or *Banana*.

It consists of very tall-growing herbaceous perennials of the Indies, for the hot-house collection, rising each with an upright, tapering, soft stem, fifteen or twenty feet high; adorned at top all around with enormous leaves, two or three yards long, and proportionably broad; and from their centre a large fungus flower stalk; terminated by a vast nodding spadix of monopetalous, ringent flowers; protruded from the spatha; succeeded by a great cluster of cucumber-shaped fruit, a single cluster weighing sometimes forty or fifty pounds; are esculent and of a delicious flavour.

Class and order, *Polygamia Monoecia*.

Characters.] **CALIX**, male, female, and hermaphrodite flowers on the same spadix, having female-hermaphrodites on the lower part, and male-hermaphrodites above, all in clusters, each bunch having a spatha for a cup, which is deciduous. **COROLLA**, each floret of the spadix is ringent, forming an upper lip, and a nectarium the lower lip. **STAMINA**, in the females six subulate filaments, five of them in the corolla, the other in the nectarium, and is double the length of the others, and terminated by a linear antheræ, the rest have none; but in the males are equal in the length, and have all antheræ. **PISTILLUM**, a large, long, triquetrous germen below the receptacle, a cylindric erect style, and capitated roundish stigma, but no stigma in the males. **PERICARPIUM**, in the females a very long, fleshy, obsoletely-triquetrous, trilocular, baccaceous fruit.

The plants of this genus having stems so soft and porous as not to deserve the name of trees, only in stature, especially as they are perennial only in root, the stems dying down to the ground annually in their native soil, after having borne their crop of fruit; they are naturally so quick in growth, as to shoot from the bottom to fifteen or twenty feet height, flower, and produce ripe fruit, all in the space of nine or ten months: the stem is about half a foot thick, and of so soft a nature, as it may be easily cut down at one stroke.

The species are;

Musa Paradisiaca.

Tree of Paradise, or Common Plantain-tree.]

Hath a strong, fibrey, very spreading root; an herbaceous, upright, taper stem, rising fifteen or twenty feet high; terminated by a cluster of very large leaves, about two yards long, and half a one broad; and a large,

long, nodding spadix of whitish-yellow, polygamous flowers, having the males persistent; succeeded in the others by an exceeding large cluster of long, narrow, yellowish, delicious fruit.

Some authors have supposed this tree, from the prodigious size of its leaves, to be that whose leaves our first parents used for cloathing in paradise; and also that the fruit is the forbidden apple which Eve gave to Adam: the sacred text, indeed, calls the leaves employed for this purpose, fig leaves; but the fruit of this is also often by the most antient authors called a fig, its nature and taste also resembles that fruit; and its leaves, by reason of their great size and solidity, were much more proper for a veil or covering than those of any species of *ficus*, which being seldom more than eight or ten inches long, and five or six broad, whereas those of the species of this genus, *Musa*, are two or three yards long with proportionable breadth, could not fail of being pitched upon in preference to all others, especially as they might be easily sewed together with the numerous thread-like filaments, that may with the utmost facility be peeled from the stem of the tree.

²MUSA *Sapientium*.

Sapient, Spotted Musa, or Banana-tree.] Rises with an upright, herbaceous, spotted stem, twelve or fifteen feet high; terminated by a cluster of leaves near two yards long, and half a one broad; a large nodding spadix of flowers, having the males deciduous; and large clusters of short, oblong, very luscious fruit.

³MUSA *Bihai*.

Bihai, or Broad-leaved Musa.] Rises with an upright soft stem, fifteen or twenty feet high; with leaves near three yards long, and one broad; and an erect spadix of flowers, having a persistent spatha; succeeded by large clusters of fruit.

These curious exotics thrive freely here in our stoves, flower and produce their enormous bunches of fruit in tolerable perfection; but as the plants grow very tall, and the leaves so exceeding large, they require very capacious stove-room, both in width and height: they must be potted in large pots of rich mould, and plunged constantly in the bark-bed, watering them plentifully in summer three or four times a week, and about twice in winter.

Their propagation is by suckers arising from the root, particularly after having fruited,

which may be taken off at any time in summer, with fibres to their bottom, planted in pots, and plunged in the bark-bed, and they will readily grow; observing according as their roots advance in growth to shift them into larger pots.

MUSCI, Mosses, a tribe or family of imperfect plants, which constitute the second order of the twenty-fourth class, *Cryptogamia*. See CLASSIS.

The plants of this order are for the most part so exceedingly minute, that their fructification are either entirely concealed, or, from their minuteness, or situation, are imperfectly visible. There are of this order not less than eleven genera, each of which comprehending many species, and are mostly very diminutive and creeping; with exceedingly weak stems, creeping and rooting as they extend, closely set with small close-fitting leaves; and extend themselves in a tufted manner, forming a sort of carpet on the ground, trees, and stones; the smallest seldom exceed the third of an inch in height, and the largest not above five or six; mostly perennial and evergreen, delight chiefly in moist shady situations, and are remarkably slow of growth; the flowers so very small that their fructifications have not by the finest glasses been yet perfectly discovered, so as to distinguish their sex; though supposed to be universally male and female distinct; sometimes they sit close to the branches, and sometimes elevated upon long slender foot-stalks, and are succeeded by seed, by which they propagate themselves.

Though from the exceeding minuteness of these plants, it was formerly supposed they were only excrescences produced from the earth, trees, &c. but are no less proper plants than those of greater magnitude, though imperfectly visible in some of their essential parts; for many insects are so small that they are hardly visible, much less so must be their eyes, mouth, &c. yet they possess all the perfect parts of life; so it is of the order of plants under consideration, being possessed of proper flowers and seed.

The supposed male flowers consist entirely of the antheræ and their covering; a sort of very small cawl-shaped *calyptra*, suspended over the tops of the stamina, like an extinguisher.

The supposed female flowers are generally formed into a vastly small cone, composed of numerous scales, each said to contain in its wing a single seed, as fine as the smallest dust.

None

M Y R

None of these plants are ever cultivated, so only mention them for their singularity, and as constituting the second order of the remarkable class *Cryptogamia*.

Some of the Mosses grow in great plenty upon trees, particularly fruit-trees growing close in orchards, especially on cold, moist, barren soils, and frequently prove very injurious to such trees: the only remedy is to cut down some of the trees to admit the sun and air, and then thin the branches of the remainder; and in winter with an instrument of iron hollowed on the edge to fit the branches, scrape off the roughest of the Moss, and by two or three repetitions it will be destroyed, but more effectually if the ground between the trees is also ploughed or digged a due depth, to give vigour to the roots, that the trees may assume a free growth at top.

Most of the plants of this numerous tribe have the singular property, after being preserved dry several years, that being moistened they will resume their original verdure.

Some of these plants have a wonderful efficacy in preserving dry such bodies as are susceptible of moisture, and retaining for a long time the humidity of young plants out of ground; for which reason tender young plants or cuttings, &c. as are to be sent to any distance, if wrapped up in some sorts of moss, it will greatly preserve their vegetative faculty.

MYRICA, Candleberry Myrtle.

The plants are of the shrub kind, consisting of hardy deciduous shrubs for the pleasure-garden, and ever-greens for the greenhouse; all of which rising with shrubby, branching stems, from about three to five feet high; garnished with oblong, simple, entire leaves; and dioecious, apetalous flowers in amentums; succeeded by clusters of small berries; which of some of the species affords a sort of green wax, with which candles are made; hence the name of Candleberry Myrtle.

Class and order, *Dioecia Tetandria*.

Characters.] **CALIX**, male and female flowers on separate plants, in oblong, oval amentums, imbricated on all sides, formed of many small, concave, moon-shaped scales, serving as calixes, each containing one flower. **COROLLA**, no petals. **STAMINA**, in the males four, and sometimes six filaments, and great didymous antheræ, with the lobes bifid. **PISTILLUM**, in the females an oval germen,

M Y R

two styles, and simple stigmas. **PERICARPIUM**, an unilocular berry, having one seed.

There are four species in the English gardens, two of them hardy and deciduous, and the others tender and ever-green.

Hardy Deciduous Kinds.

¹**MYRICA** *Cerifera*.

Ceriferous, or Wax-bearing Myrica, commonly called Candleberry Myrtle.] Hath an upright shrubby stem, branching five or six feet high, with yellowish-brown branches; lanceolate, slightly-ferrated, shining green leaves, three inches long, and one broad, placed irregularly on very short foot-stalks; and dioecious, amentaceous, small, whitish flowers at the sides of the branches; succeeded in the female plants by clusters of small blue berries, replete with a sort of green waxy matter.

Variety.] Dwarf Carolina Candleberry Myrtle with broad leaves.

They are natives of North America, but have been long residents of our gardens, and both the varieties are choice furniture for the shrubbery; whilst young they often retain their leaves like an ever-green great part of winter; but when older they constantly shed their leaves in autumn: the leaves of both sorts possess a very agreeable fragrance of an aromatic nature, like a Myrtle.

It is from this species the North Americans procure the wax for candles, before mentioned.

²**MYRICA** *Gale*.

Gale, Sweet Willow, or Dutch Myrtle.] Hath under-shrubby, upright stems, branching three or four feet high; lanceolate, slightly-ferrated leaves, an inch and a half long, on very short foot-stalks; and dioecious, amentaceous, small, whitish flowers; succeeded in the female plants by clusters of small berries.

This grows naturally on some boggy grounds both in England and other northern parts of Europe: it is cultivated as furniture for the shrubbery, but must have a moist situation.

Ever-green Kinds for the Green-house.

³**MYRICA** *Quercifolia*.

Oak-leaved African Myrica.] Hath a shrubby stem, branching three or four feet high; oblong, oppositely-sinuated, close-fitting, smooth leaves,

leaves, an inch and a half long, and half as broad; and whitish-green flowers, in oval amentums; succeeded by small round berries.

Variety.] With hairy leaves.

MYRICA Cordifolia.

Heart-leaved Ethiopian Myrica.] Hath a shrubby, slender stem, branching four or five feet high; heart-shaped, serrated, close-fitting leaves; and roundish amentums of flowers; succeeded in the female plants by small berries.

All these shrubs flower in June and July, which in the first and second sorts are succeeded by berries in our gardens; but in the others rarely any in England; neither flowers nor fruit are ornamental; so that the merit of the shrubs consists in the variety and aromatic fragrance of their leaves, and for which they demand admittance in every good collection; and are all kept in the nurseries for sale.

The flowers consist of oblong-oval amentums of many apetalous florets. See the *Characters*.

Their Propagation.

Their propagation is by seed, layers, and suckers.

By Seed.—The seed are procured from the places where the respective species grow naturally. Sow them as soon as they can be procured, in boxes of rich earth, half an inch deep, and at the approach of hot weather move them to shade, to remain all summer, they sometimes come up the same year, if sowed early, otherwise often not till the second; however in winter remove the hardy kinds under a warm hedge, and the others in garden-frames to have shelter of the glasses in bad weather, and they will all come up the second spring; giving water all summer, shelter again in winter, and in spring plant them out, the hardy sorts in nursery rows to remain two or three years till proper for the shrubbery; and plant the tender sorts in pots, to be placed among the green-house plants.

By Layers.—Chuse for this operation the young wood, which lay by slit-laying in autumn; and during the following summer water them plentifully in dry weather, and they will be tolerably rooted by the autumn following; but if not, let them remain another year, to effect it properly; then transplant the hardy sorts in nursery-rows, to remain till

fit for the shrubbery; and the tender kinds plant in pots to manage as green-house plants.

By Suckers.—The hardy sorts sometimes send up a few suckers, which in autumn may be taken up with roots, and planted out in the nursery for a year or two.

Cuttings of all the sorts may also be tried, though not to be depended on: chuse the quite young shoots, and if some are planted in pots plunged in a hot-bed and covered close with a hand-glass, some of them may probably take root.

MYRTUS, Myrtle-tree.

This celebrated plant of antiquity comprises many elegant varieties of the shrub kind, for our green-house collections, and some beautiful species for the hot-house, all delightful ever-greens of great fragrance; rising with branchy stems eight or ten feet high, or more, in their native soil; closely garnished with simple entire leaves, and quinquepetalous, hermaphrodite flowers from the sides of the branches, succeeded by oval berries.

Class and order, *Icosandria Monogynia*.

Characters.] CALIX, is monophyllous, five-parted, placed on the germen, and permanent. COROLLA, is quinquepetalous, the petals oval, and inserted into the calix. STAMINA, twenty or more capillary filaments inserted into the calix, and very small antheræ. PISTILLUM, a germen under the corolla, slender style, and obtuse stigma. PERICARPIMUM, an oval umbilicated trilocular berry, each cell having one kidney-shaped seed.

To this genus Linnæus adds the *Pimento*, or all-spice, a beautiful ever-green aromatic, and hot-house plant.

There are about four species of this genus retained in the English gardens; one is the common Myrtle, a very comprehensive species, being the parent of all those different varieties of Myrtle found in our green-house collections: the other three species are for the stove.

Green-house Kind.

One species only is for the green-house, the common Myrtle, but which, as before observed, affords many varieties.

The species are;

MYRTUS Communis.

Common Myrtle-tree.] Rises with a shrubby, upright, firm stem, branching numerously all around into a close full head, rising eight or ten feet high; very closely garnished with

with oval-lanceolate, entire, mostly opposite leaves, from half an inch to an inch and a half long, and one broad, on short foot-stalks; and numerous, small, pale flowers from the axillas, singly on each foot-stalk, having diphyllous involucrum; each flower succeeded by a small, oval, dark-purple berry.

The botanic description is, *Myrtus* with solitary, or singly-placed flowers, having a diphyllous involucrum.

The most material varieties are;

Broad-leaved Roman Myrtle.—Hath oval, shining, green leaves, an inch and a half long and one broad, and is remarkably floriferous.

Gold-striped broad-leaved Roman Myrtle.

Broad-leaved Dutch Myrtle.—Hath spear-shaped, sharp-pointed, dark-green leaves, an inch long, and about three quarters of one broad.

Double-flowered Dutch Myrtle.

Broad-leaved Jews Myrtle.—Having the leaves placed by threes at each joint; by which particular circumstance this species is in universal estimation among the Jews in their religious ceremonies, particularly in decorating their tabernacles, and for which purpose many gardeners about London cultivate this variety with particular care, to sell to the above people, who are often obliged to purchase it at the rate of six-pence or a shilling for a small branch; for the true sort having the leaves exactly by threes, is very scarce, and is a curiosity; but by care in its propagation, taking only the perfectly ternate-leaved shoots for cuttings, it may be encreased fast enough, and is worth the attention of the curious, and particularly those who raise Myrtles for the London markets.

Orange-leaved Spanish Myrtle.—Has oval, spear-shaped leaves, an inch and a half long or more, and one broad, in clusters round the branches, and resemble the shape and colour of orange-tree leaves.

Gold striped-leaved orange Myrtle.

Common Upright Italian Myrtle.—Hath its branches and leaves growing more erect, the leaves oval, lanceolate-shaped, acute-pointed, and near an inch long, and half a one broad.

Silver-striped upright Italian Myrtle.

White-berried upright Italian Myrtle.

Portugal Acute-leaved Myrtle.—Has spear-shaped, oval, acute-pointed leaves, about an inch long.

Box-leaved Myrtle.—Hath weak branches, small, oval, obtuse, lucid-green, closely-placed leaves.

Striped box-leaved Myrtle.

Rosemary-leaved Myrtle.—Hath erect branches, small, narrow, lanceolate, acute-pointed, shining, green, very fragrant leaves.

Silver-striped rosemary-leaved Myrtle.

Thyme-leaved Myrtle.—Hath very small closely-placed leaves.

Nutmeg Myrtle.—Hath erect branches and leaves; the leaves oval, acute-pointed, and finely-scented like a nutmeg.

Broad-leaved Nutmeg Myrtle.—Silver-striped-leaved.

Cristated, or Cock's-comb Myrtle, frequently called Bird's-nest Myrtle.—Hath narrow, sharp-pointed leaves, cristated at intervals.

These are the principal varieties of the *Myrtus Communis*; but of which sorts there are several intermediate varieties of less note; and more may still be obtained from seed, though the plants are rarely raised from seed in England, but mostly by slips and cuttings.

They are all beautiful ever-green shrubs of exceeding fragrance; exotics originally of the southern parts of Europe, and of Asia and Africa, and consequently in this country require shelter of a green-house in winter; all of which, though rather of the small-leaved kind, have their foliage closely placed, and remain all the year, and are very floriferous in summer; and when there is a collection of the different sorts, they afford an agreeable source of variety with each other; they therefore claim universal esteem as principal green-house plants, especially as they are all so easily raised from cuttings, and of such easy culture, as to be attainable in every garden, where there is any sort of green-house, or garden-frames furnished with glasses for protecting them in winter from frost: but some of the broad-leaved sorts are so hardy as to succeed in the full ground, against a south-wall and other warm exposures all the year, by only allowing them shelter of mats occasionally in severe frosty weather: so that a few of these sorts may be also exhibited in a warm situation in the shrubbery: observing, however, all the sorts are principally to be considered as green-house plants, and a due portion of them must always remain in pots to move to that department in winter. See their *Propagation and General Culture.*

Stove Kinds.

There are several species of the stove temperature, as being natives of the Indies; but there

there are not more than the four following sorts commonly met with in the English gardens, all of which are beautiful ever-greens, with larger leaves than the *Myrtis Communis*, and are mostly strong aromatics.

¹*MYRTUS Zelanica.*

Ceylon White-berried Myrtle.] Hath a shrubby upright stem, branching erectly six or eight feet high; oval, shining-green, opposite, very odoriferous leaves, on short foot-stalks; and all the branches terminated by pedunculi, each sustaining many flowers; succeeded by snowey-white berries, but rarely in England.

²*MYRTUS Pimenta.*

Pimento, or Jamaica All-spice-tree.] Rises with an upright tree-stem, branching regularly, twenty or thirty feet high, having a smooth brown bark; large, oblong-oval, stiff, shining, very odoriferous leaves, like those of bay, placed alternate; and at the sides and termination of the branches large loose bunches of greenish flowers; succeeded by round, dusky, hard, spicy fruit, called all-spice, or Jamaica pepper.

This species is wholly an admirable fine aromatic, its leaves are remarkably fine scented; and its fruit is that valuable spice, Jamaica pepper, or all-spice, so called because it is supposed to partake of the odour and taste of most other spices. The tree grows in great abundance in the island of Jamaica, where its fruit is made a considerable branch of trade; is generally gathered a little before it acquires full growth, and dried in the sun ten or twelve days, is then packed up ready for exportation to Europe.

³*MYRTUS Dioeca.*

Dioecious American Myrtle.] Rises with an upright tree-stem, branching many feet high; oblong, thick, opposite, odoriferous leaves; and at the axillas and ends of the branches pedunculi dividing into trichotomous panicles of dioecious flowers; succeeded by small, globular, spicy berries.

Every part of the tree is a strong aromatic.

⁴*MYRTUS Brasiliانا.*

Brazilian Inodorous Myrtle.] Rises with a branching stem, having a whitish bark; broad, oval, shining, opposite, inodorous, or scentless leaves, and naked pedunculi, sustaining solitary flowers with ciliated petals; succeeded by large oval fruit.

All these five species of *Myrtus* are exotics of the shrub and tree kind, though in this country, as being confined in pots, the largest

of them assume only the growth of moderate shrubs. The first species, Common Myrtle, is considerably the most noted species of this genus in this country; where in most of our green-house collections one or other of the varieties is found in tolerable plenty; but all the varieties of it highly merit notice. The other four species are rare in England, they however are retained in many curious gardens, in the stove collection, more particularly the *Pimento*, which is a very beautiful odoriferous ever-green, and exhibits a fine variety in the stove at all seasons: in short all the species, both green-house and stove kinds, have a pretty effect as ever-greens, and some of the sorts flower very ornamentally, particularly of the Common Myrtle.

With respect to flowering, all the varieties of the *Myrtus Communis* flower here in July and August, most of which are very floriferous, but more particularly the broad-leaved Roman kind, which is often covered with flowers; and in some of the sorts are succeeded here by berries ripening in winter. Some of the stove kinds also flower here, but are rarely succeeded by fruit in England.

The flowers, however, of most of the sorts are small, but numerous; and are all formed each of five oval petals, and many stamina. See the *Characters*.

As all the species require occasional shelter here, they must be kept always in pots, for moving to the proper places of shelter, according to their nature; the *Myrtus Communis* and varieties to the green-house in winter; the others to the stove, to remain all the year; therefore let all the sorts be potted in light rich earth, and, as they advance in growth, shift them into larger pots, managing the Myrtles as other green-house shrubs; and the stove-kinds as other woody exotics of the stove. See their *Propagation and General Culture*; also GREEN-HOUSE and STOVE PLANTS.

But, as we before observed, the broad-leaved *Myrtus Communis*, being hardier than the smaller-leaved kinds, some of them may also be turned out into the full ground in a warm situation against a wall, &c. allowing them shelter of mats in frosty weather, and mulch the ground over their roots: they will frequently succeed tolerably, and effect a good variety in such places.

Propagation and General Culture.

The propagation of the *Myrtus Communis* and varieties is effected abundantly by slips

or cuttings, also by layers; but as the former strike freely, it is the most eligible method for raising any considerable quantity, as also the handfomest plants, which may be struck either in natural earth, or by aid of hot-beds, to bring them more forward.

By Slips and Cuttings.—The young shoots, either of the same or former year's growth, of from about two or three to five or six inches long, either slipped or cut off, are the proper parts for planting; and, as above said, may be struck either in natural earth without artificial heat, or by aid of hot-beds; but by the latter you may greatly facilitate the rooting and first effort of growth. By either method the work may be performed any time from March or April until August, though June or July is the most common season practised, especially when intended to use the shoots of the year, which are generally in prime order in July, and often strike freely the same year without aid of hot-beds; the young shoots of the former year will also often strike tolerably, especially if planted in spring or early in summer, or by aid of hot-beds may be made to strike root readily at any time in the spring or summer season. By aid of a hot-bed, however, all the sorts, both of one or two years shoots, may be greatly facilitated in rooting: a dung hot-bed under common frames and lights will do, though a bark hot-bed of a stove, &c. is considerably the most eligible and effectual, and may be readily used any time in spring and summer for this purpose; and by which assistance vast numbers of cuttings may be struck with the utmost facility in a short time, with but little trouble; and plants thus struck in spring or early in summer, may be so much forwarded as to form pretty little plants the same year, and be fit to pot off separately early in autumn. We will, however, exhibit separate directions for both methods, i. e. striking them in natural earth, and by hot-beds.

First, by striking them in natural earth: we noticed above, that the planting might be performed any time from March till August; observe in respect to this, that if you would begin in spring, or early in summer, you must chuse principally the shoots of the former year; and if you do not begin planting till June or July, but particularly the latter month, the young shoots of the year will be arrived at a proper growth, and will root freely. Observe in chusing the shoots, either of the former or same year, to chuse the straight

clean growth, of from about two or three to four or five inches length, and as robust as possible; which divest of the lower leaves, two parts of three of their length, they are then ready for planting; then having some large wide garden-pots, or rather flat wide earthen pans, six inches deep, with holes at bottom to discharge the wet, such as are used by the setting-gardeners about London, who raise prodigious quantities of Myrtle annually for the supply of the markets; fill the pots or pans with light rich mould, in which plant the slips or cuttings, many in each pot or pan, if required, putting them in within an inch of their tops, and about an inch or two asunder; give directly some water to settle the earth closely about each plant; then either plunge the pots, &c. in a shallow garden-frame, and put on the glasses, or under oiled paper-frames, or cover each pot or pan close with a low hand-glass, which is rather the most eligible for facilitating their rooting; in either method, however, observe to plunge the pots in the earth, and keep them close covered with the glasses, &c. where practicable, to exclude the air, for this will promote the quick emission of roots the same season; remembering to afford them occasional shade from the mid-day sun, but if under oiled paper none is wanted; and give plenty of water three or four times a week at least, or oftener in very hot weather; thus they will be rooted in a month or six weeks, which will appear by their exhibiting signs of growth at top; at which period inure them gradually to the full air, still supplying them duly with water during the hot weather, whereby they will shoot in height; and those planted early will often branch out laterally a little the same year, so as to commence pretty little plants by autumn: let them remain in the full air until October, then remove them in their pots or pans into the green-house, or under a good garden-frame for the winter, and in spring the forwardest in growth may be potted off separately in small pots; but if rather small and weak, or but indifferently rooted, let them have another summer's growth, and pot them out separately in September or spring following, as it shall seem proper; managing them as other green-house shrubs of similar temperature, and shift them into larger pots annually, or according as they shall require.

For want of frames and glasses of any sort to strike the cuttings under, oiled paper-frames.

frames may be used, which may be obtained at an easy expence, and are excellent for striking many sorts of cuttings; they admit the rays of light and heat sufficiently, at the same time afford such an agreeable shade that no other is required, and which is of such a nature as greatly to promote the rooting of cuttings.

But Myrtle cuttings will sometimes strike in the open ground without any coverings; and if planted betimes in summer, either in pots or pans, as above mentioned, and plunged in a shady border, or the slips planted in the earth of such a border of rich earth; and in either method plentifully supplied with moisture, they will often root tolerably the same year, and shoot a little at top; though rarely make so good plants by autumn as those forwarded in the above manner, nor near so strong as those struck in the following method by aid of artificial heat.

By Aid of Hot-beds.—By the assistance of hot-beds, either that of dung, under frames and glasses, oiled paper-frames, or in the bark-bed in the stove, &c. but rather the latter; but by either method the rooting and first growth of the slips may be greatly forwarded; a bark-bed in particular in the stove, &c. is the most eligible, and effectual for this purpose, and in which vast numbers of slips or cuttings may be readily struck, at any time from March until August, both in shoots of the former year, and of the same year's growth, from three or four to five or six inches long: and that those struck in spring and early in summer, will form fine young plants for potting off early in the proceeding autumn. However, in default of bark hot-beds, one of dung under glasses may suffice; but if furnished with both, give preference considerably to a bark-bed.

Therefore being furnished with pots, or rather wide pans, as before directed, filled with fine rich earth, take off a quantity of slips or cuttings, the most robust shoots; which if in spring or early in summer, those of the former year must be chosen; and at a more advanced season, those of the same year will be arrived to a proper growth for this purpose: observing for either sort to strip off the under leaves, as before advised; then plant them in the pots or pans, as already exhibited, give a general watering, and directly plunge them in the hot-bed, affording occasional slight shade from the fierce sun, and water them frequently; they will thus root in a fortnight

or three weeks, and advance in growth; observing to inure them gradually to the open air, if the temperature of the weather permits, in a sheltered situation; or in a frame, if cold weather, and from thence by degrees expose them fully for the remainder of the summer, in a sheltered place, and supply them duly with water in dry weather, they will be fine plants by September; and, as before observed, those raised early will be then fit to pot off singly into small pots; and the latter plantings will be fit for potting in spring, or autumn following; removing them all to shelter towards the middle or latter end of October.

In striking the cuttings by the above method, if, as soon as they are planted and plunged in the hot bed, each pot or pan is covered close with a low hand-glass, it will still contribute to facilitate their rooting the more effectually; for being close covered, it will force out roots sooner, and prevent the cuttings from running up weak; observing, however, when they begin to advance at top, to remove the glasses.

By the above methods of artificial heat, in striking Myrtle cuttings, you may make two or three plantings each season, where large quantities are required; the first planting in March or April, of the best last year's shoots; the second early in June, of the succeeding best shoots; or about Midsummer, or soon after, may plant shoots of the year; and in a month or six weeks after, the next best shoots also of the same year will be come forward, and of which may be made another plantation; plunging each planting in the bark-bed, &c. as above; thus may you have three young crops advancing in different stages of growth each year in store-pans; some ready for potting off singly every autumn and spring, whereby a large stock may be always kept up, as is necessary for those who raise them for sale, especially about London, for Covent-garden market, where amazing quantities are brought for sale at all times of the year, which sell from six-pence to half a crown per pot, according to the size and goodness of the plants.

Those who propagate large quantities of these plants annually, should always keep some strong bushy plants for furnishing slips or cuttings for this purpose.

Propagation by Layers.—Such plants as are furnished with young bottom branches or shoots situated low enough for laying, may be

be layed in spring, in the usual way; every shoot will readily emit roots, and be fit to transplant into separate pots in autumn.

By Seed.—These may be sowed in spring, in pots of light mould, and plunged in a moderate hot-bed; they will soon come up, which when two or three inches high, pot them off separately in small pots; manage them as the others, and probably as they advance in growth may discover some new varieties.

With respect to the general culture of all these sorts of common Myrtle, they succeed in the open air from May until the end of October, when remove them in their pots to the green-house, or into a deep garden-frame under glasses, allowing air freely in all mild weather, by opening the glasses wide; giving water once or twice a week or ten days in winter, and every other day at least in summer; and according as they advance in growth, shift them into larger pots, which may be necessary every year to one or other of them. See GREEN-HOUSE PLANTS.

In training these shrubs, observe, as they naturally branch out all around, so to be feathered quite to the bottom, in a beautiful manner, that if you design any small form standards, with bushy heads for variety, trim off the lower shoots gradually so as to form a straight clean stem, two or three feet high or more, then suffer them to branch out every way at top to form a head: but those which are intended to be low and branchy quite to the bottom, should have the lateral shoots encouraged nearly in their own way, whereby they will be feathered all the way from bottom to top, and assume a more picturesque appearance.

Let them afterwards for the most part assume their own natural growth, except when their heads become thin, straggling, and irregular; then shorten with a knife such shoots as shall appear proper, either in order to force out laterals to make good deficiencies, or to form regularity.

Never practise clipping these shrubs with garden-shears into globes, pyramids, &c. as sometimes done; but let all necessary trimming be performed by knife, and that only in cases of irregularity as above, for they always appear the most agreeable when they grow nearly according to nature.

If their heads at any time become very irregular, or thin and stubby, by heading down all the branches pretty short in spring,

and shifting them into larger pots of fresh mould, with the ball of earth about their roots, affording plenty of water all summer, they will all branch out again numerously, and form handsome full heads by the succeeding autumn.

Sometimes when Myrtles are become very weak straggling shooters, with naked unsightly heads; if headed down, as above, in April or May, turned out of the pots, and plunged in a warm border of rich soil, giving plenty of water, they, by sending their fibres into the fresh earth, often break out with fresh vigour, and become fine full-headed plants by the end of summer, when they may be taken up with balls and potted in fresh earth.

As the sorts in general encrease in size, shift them into larger pots. See GREEN-HOUSE PLANTS and SHIFTING PLANTS.

Propagation of the Stove Kinds.

The four kinds of *Myrtus* for the stove, are commonly propagated by seeds; though, when any are pretty branchy, it may also be tried by layers and cuttings.

By Seed.—This is procured from abroad by the dealers, preserved in sand, &c. and arrives in spring, which sow as soon after they arrive as possible, in pots of fresh rich mould, and plunge them in a bark-bed, they will come up the same season; which, when of two or three inches height, plant out in separate small pots, plunge them also in the bark-bed, supply them with water, and manage them as other woody plants of similar temperament.

By Layers.—The first sort in particular often branch out low; lay some of the young shoots in spring, by slit-laying or wiring, &c. plunging the pots in which they are layed in the tan; they will probably be rooted in one year, though it is frequently two before they strike good root, when pot them off separately.

By Cuttings.—In May or June cut off some short young shoots from such of the plants as afford them, plant them in pots of fresh compost, plunge them in the bark-bed, and cover them close with a low hand-glass, giving due refreshments of water; they will soon take good root the same year, and be fit to plant in separate small pots.

In the general management of these sorts, keep them always in the stove, except about a month

a month in the heat of summer, when they may be trusted abroad. Let them shoot nearly in their own way, keeping them, however, to upright stems, and suffer their heads to branch out according to nature, except

just reducing very irregular shoots: give frequent waterings in common with other woody plants of the stove department, and shift them occasionally into larger pots. See STOVE PLANTS.

N.

NARCISSUS (*Narcissus*) Daffodil.

This genus retains a numerous family of eminent, bulbous-rooted, herbaceous perennials of the flowery race, for embellishing the pleasure-garden, having all large tunicated, bulbous roots, crowned with several long narrow leaves, and erect naked flower-stalks, rising from about eight or ten to fifteen or eighteen inches high, each terminated by a spatha, protruding one or more large hexapetalous flowers, having a large cup-shaped nectarium in the centre.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, is an oblong, compressed spatha, opening on one side, and withering. COROLLA, six large, oval petals, inserted into, and surrounding a large cup-shaped nectarium; the nectarium is monopetalous, and placed directly in the centre of the corolla, and resembles a sort of cup or dish. STAMINA, six short awl-shaped filaments affixed to the tube of the nectarium, and oblong antheræ. PISTILLUM, a roundish three-cornered germen below the corolla, long slender style, and trifid stigma. PERICARPIUM, a roundish, obtuse trigonous, trilocular, trivalvular capsule, having numerous roundish seeds.

To this celebrated genus belong also all the sorts of *Jonquilla*, or *Jonqui*.

There are about twelve species, some of them furnishing a numerous train of beautiful varieties; one of the species, Common Daffodil, grows wild in England, &c. but it nevertheless possesses merit as a garden-flower: most of the others are originally of foreign growth, but are hardy enough to prosper in our flower-borders, and several of

which have long adorned our gardens. All of them produce their flowers from a spatha or sheath; some having but one, and some many flowers from the same spatha, though the greater part are uniflorous, but the multiflorous kinds, called *Polyanthos Narcissus*, having superior merit, are in most esteem among the florists; but all the sorts are very ornamental flowers.

Each flower of all the species of this genus being furnished with that appendage, called *nectarium*, which in these plants is always placed in the centre of the corolla, and which, as it in shape resembles a sort of cup or little dish, among gardeners it is commonly, but erroneously called the cup; therefore in the following descriptions of the species, when we occasionally mention the cup, it must always be understood the nectarium.

The species are;

1. *NARCISSUS, Pseudo-Narcissus.*

Bastard Narcissus, or common Yellow English Daffodil.] Hath a large, oblong, bulbous root; sending up several long, narrow, light-green leaves, a foot long and half an inch broad, a little hollow along the middle; amidst them, an upright flower-stalk, twelve or fifteen inches high; terminated by an uniflorous spatha, protruding one large yellow flower, having oval petals, and a bell-shaped, erect, golden cup or nectarium, waved, and equal in length with the corolla; flowering in March and April.

Varieties of this are.] Common single-flowered pale-yellow Daffodil—deep-yellow—golden-cupped—double flowered—long tubed-flowered—short tubed—dwarf-stalked.

This

This species grows wild in great plenty in many of our woods and coppices, and under hedges in several parts of England; from which places in the counties round London the herb folks bring prodigious quantities in the spring of the year, when in bloom, root and all, and sell them about the streets. Its commonness renders it of but little esteem with many; considered, however, as an early and elegant flower, together with its exceeding hardiness, and easy culture, are sufficient merits to entitle it to a place in every garden.

²NARCISSUS *Bicolor*.

Two-coloured Incomparable Narcissus.] Hath a large, oblong, bulbous root; crowned with long, narrow, dark-green leaves, twelve or fourteen inches long; an upright flower-stalk, about fifteen inches high, terminated by an uniflorous spatha, protruding one large flower with white petals, and a bell-shaped, spreading, golden nectarium, waved on the margin, and equal in length with the corolla; flowering in April.

Varieties.] Common single-flowered—femi-double flowered—double-flowered—double-flowered, with the interior petals some white, and some yellow—with sulphur-coloured flowers.

³NARCISSUS *Poeticus*.

Poetic Daffodil, or common White Narcissus.] Hath a large bulbous root; crowned with several long, narrow, light-green leaves, a foot in length, and near half an inch broad, a little hollow along the middle; amidst them an upright flower-stalk twelve or fifteen inches high, terminated by an uniflorous spatha, protruding one large, expanded, nodding, pure-white flower, having a short rotated or wheel-shaped nectarium, slightly crenated and fringed on the border with a purple circle; flowering in May, and is of exceeding fragrance.

Varieties.] With purple-cupped flowers—yellow-cupped flowers—double-flowered: all of them with entire white petals.

This species is the ancient celebrated *Narcissus* of the Greek and Roman poets, which they so greatly extol for its extreme beauty and fragrance.

⁴NARCISSUS *Bulbocodium*.

Bulbocodium, Yellow Daffodil, commonly called Hoop-petticoat Narcissus.] Hath a small bulbous root, crowned with several narrow, subulate, rush-like leaves, six or eight inches long; amidst them a slender, taper flower-stalk, six inches high, terminated by an uniflorous spatha, protruding one yellow flower,

having the nectarium much larger than the petals, and very broad and spreading at the brim; flowering in April.

From the large spreading nectarium of this species, which being three or four times longer than the petals, narrow at bottom, and widening gradually to the brim, so as to resemble the shape of some old-fashioned hoop-petticoats, it obtained the name Hoop-petticoat *Narcissus*.

⁵NARCISSUS *Serotinus*.

Late-flowering small Autumnal Narcissus.] Hath a small bulbous root; crowned with a few narrow leaves; amidst them a jointed flower-stalk, eight or nine inches high, terminated by an uniflorous spatha, protruding one white flower, having a short, six-parted, yellow nectarium; flowering in autumn.

⁶NARCISSUS *Tazetta*.

Tazetta, or Multiflorous Daffodil, commonly called Polyanthos Narcissus.] Hath a very large, roundish, bulbous root; long, narrow, plane leaves; an upright flower-stalk, rising from ten or twelve inches to a foot and a half high; terminated by a multiflorous spatha, protruding many large, spreading, white and yellow flowers in a cluster, having bell-shaped nectariums shorter than the corolla; flowering in February, March, and April, and is very fragrant.

The varieties of this are very numerous, consisting of about eight or nine principal sorts, each of which having many intermediate varieties.

Principal Varieties are,] With entire white flowers in large bunches—with white petals and yellow nectariums—white petals and sulphur-coloured nectariums—white petals and orange-coloured nectariums—with entire yellow flowers—yellow petals and orange coloured cups—yellow petals and sulphur-coloured cups—double-flowered of each of these varieties: all which are multiflorous, or many flowers in a cluster from each spatha.

Of each of these principal varieties are many intermediate ones, as above observed, varying from each other in some little particulars; amounting in the whole greatly above an hundred in the Dutch florists catalogues, each variety distinguished by a name according to the fancy of the first raiser of it; which varieties, however, and their names often varying in time and different places, it would be unnecessary to attempt the enumerating any other here than the above principal standing varieties they are all very pretty flowers, and

and make a charming appearance in the flower-borders, &c. they are also finely adapted for blowing in glasses of water, or in pots, to ornament rooms in winter.

The name *Polyanthos Narcissus*, usually given to this species, signifies Many-flowered Narcissus, many flowers growing from the same spatha, in a close head or cluster, like a truss of the *Polyanthos Primrose*, which has also the name *Polyanthos*, from many flowers growing in a head. See PRIMULA.

Jonquil Kinds.

There is but one species of the true Jonquil, but admits of several varieties, all of the multiflorous kind, and very pretty spring-flowers of delightful fragrance, and have long ornamented many curious flower-gardens.

¹*Narcissus Jonquilla.*

Jonquilla, or Jonquil, sometimes called Rush-leaved Daffodil.] Hath an oblong, bulbous, brown root; sending up several long, semi-taper, rush-like, bright-green leaves; amidst them an upright green flower-stalk, a foot or fifteen inches high, terminated by a multiflorous spatha, protruding many yellow flowers, often expanded like a radius, each having a hemispherical, crenated nectarium, shorter than the petals; flowering in April, and mostly of a fine fragrance.

Varieties are.] Jonquil minor, with single flowers—Jonquil major, with single flowers—starry flowered—yellow and white-flowered—white-flowered—semi-double-flowered—double-flowered—and large double inodorous Jonquil: all of them multiflorous, the singles in particular, but sometimes the doubles produce only two or three flowers from a spatha, and the singles commonly six or eight.

All the sorts of *Jonquilla* have so fine a shape, so soft a colour, and so sweet a scent, that they are some of the most agreeable spring flowers.

Less common Narcissus Kinds.

²*NARCISSUS Calathinus.*

Calathinus Multiflorous Yellow Narcissus.] Hath a large bulbous root; crowned with long, narrow, plane leaves; and amidst them an erect, robust flower-stalk, terminated by a multiflorous spatha, protruding many large, entire, yellow flowers, having a bell-shaped, slightly crenated nectarium, equal in length with the petals.

⁹*NARCISSUS Odorus.*

Odoriferous, or Sweet-scented Starry Yellow Narcissus.] Hath a bulbous root; narrow leaves; erect flower-stalk, a foot or more high, terminated by a sub-multiflorous spatha, protruding sometimes but one, and sometimes several entirely yellow flowers, having a campanulated, six-parted, smooth nectarium, half the length of the petals.

¹⁰*NARCISSUS Triandrus.*

Triandrous Rush-leaved White Narcissus.] Hath a bulbous root; very narrow, rush-like leaves; erect flower-stalk, terminated by an uniflorous spatha, protruding one snowey-white flower, having a bell-shaped, crenated nectarium, half the length of the petals, and with mostly triandrous or three stamina.

¹¹*NARCISSUS Trilobus.*

Trilobate Yellow Narcissus.] Hath a bulbous root; narrow rush-like leaves; and erect flower-stalks, terminated by a sub-multiflorous spatha, protruding sometimes but one or two, and sometimes several yellow flowers, having a bell-shaped, three-lobed nectarium, half the length of the petals.

¹²*NARCISSUS Minor.*

Minor Yellow Winter Daffodil.] Hath a small bulbous root; plane leaves, eight or ten inches long, and more than half a one broad; an erect flower-stalk, terminated by an uniflorous spatha, protruding one nodding yellow flower, with spear-shaped petals, having an obconic, six-parted, waved nectarium, equal to the length of the corolla; flowering in winter, or very early in spring.

All these twelve species of *Narcissus* are of the bulbous-rooted tribe, and universally perennial in root, but annual in leaf and flower-stalk; all of which rising annually in spring, immediately from the crown of the bulb, first the leaves, and in the midst of them the flower-stalk, one only from each root, entirely naked or leafless, each terminated by a spatha or sheath, which opens on one side to protrude the flowers, and then withers; the flowers, as before observed, are all hexapetalous, each furnished with a nectarium in the centre, and are universally hermaphrodite; they are large and conspicuous, appearing mostly in the spring season, generally from March or April until June, succeeded by ripe seed in July; then the leaves and flower-stalks decay, and the roots desist from growing for some time; at which period of rest is the only proper time to take up, or transplant the

the roots from one place to another, or to separate the off-sets; for they all multiply abundantly by off-set young bulbs from the main root, insomuch that a single bulb will in one or two years be encreased into a large cluster of several bulbs, closely placed together, and which every second or third year should be taken up at the above period in order to be separated; and each off-set so separated commences a distinct plant, which being planted again in autumn, produces flowers the following summer, alike in every respect to those of their respective parent bulbs. See **BULBUS**.

All the species are so hardy that they prosper in any common soil of a garden: observing, however, to allow the finer sorts of *Polyanthos Narcissus* in particular, principally a warm dry situation; all the others may be planted any where in the open dry borders and flower-beds.

The first seven species are those the most commonly known in the English gardens; all of which produce ornamental flowers, but the *Polyanthos Narcissus* is among the florists esteemed the chief of the *Narcissus* tribe, both on account of its mode of flowering, i. e. in a large cluster from each spatha, and from the vast source of variety it affords in the different properties of its flowers; so that almost every eminent florist cultivates this species and its varieties with great assiduity, and are often particularly industrious in raising new varieties from seed, especially the Dutch florists; and when any new variety is so obtained, it propagates itself plentifully by off-sets of the root like the other sorts, whereby the stock in two or three years will be greatly encreased.

With respect to the merit of the species in general as flowering plants, all the sorts may be considered as some of the most beautiful of our bulbous-rooted spring flowers for ornamenting the borders, &c. of the pleasure-garden; and have a very fine effect when disposed in patches in assemblage with other bulbous flowers of the spring.

The bulbs or roots of all the sorts may be had at most of the nursery gardens, and of the seedsmen, at the proper season, i. e. from September until Christmas, or even until spring.

Method of Planting, &c. of all the Sorts.

The best general season for planting all these bulbs is autumn, from about the be-

ginning or middle of September until November, in which they will flower considerably stronger, as well as furnish a greater encrease of off-sets than those planted later, or not till spring: if, however, some roots are retained out of ground until February, they will succeed those of the autumnal planting in flowering, whereby you may vary and prolong the continuance of the bloom; but these late-planted roots always flower weaker, some not at all, and at best with inferior beauty, and shorter continuance, and furnish but a bad encrease of roots; therefore always consider autumn as the proper planting season for the principal blow.

In planting them, observe the following modes of disposition.

Those you design to dispose in the open borders or other compartments, in assemblage with other bulbous flowers, &c. I should advise them to be deposited in little patches, of about three or four roots in each, planting them either with a blunt dibble, or hole them in with a garden trowel, four inches deep; in which mode of disposition they will shew their flowers more conspicuously and ornamental than if planted singly, as each patch of plants will display their flowers in a cluster, which will strike the eye most agreeably.

When intended to plant a quantity in beds by themselves, in order to exhibit a full bloom all together in one place, as is often practised to the fine *Polyanthos Narcissus*, Jonquils, &c. have the beds four feet wide, with foot and a half, or two-feet-wide alleys between; in which beds plant the roots in rows lengthways, nine inches asunder; planting them either with a blunt-ended dibble, or drill them in with a hoe, about four inches deep, and six distant in each row, covering them regularly with the earth, and rake the surface smoothly.

Having planted the roots in either of these methods, all the culture they require is to be kept clean from weeds; and they will all flower in due perfection the following spring and summer.

But the *Polyanthos Narcissus* and Jonquil, as we formerly observed, being of the multiflorous kinds, and considered of superior value and beauty; to blow them in the highest perfection, curious florists bestow particular care in their culture: some prepare beds of compost, as for the fine hyacinths, &c. and manage

manage them in the same manner, particularly the *Polyanthos Narcissus*: remark, however, that in default of such prepared composts, &c. you need not be under any great anxiety, for they generally succeed very well in any good, light, rich earth of a garden, in a warm, sunny, sheltered situation, with the beds a little elevated above the common level, out of the reach of copious moisture in winter; so having the ground formed into four-foot-wide beds, in which plant the roots in rows nine inches asunder, as before directed; and in winter and early in spring give occasional shelter of mats from cutting frosts and other inclement weather, especially after the flower-buds appear above-ground.

All the sorts of these bulbs, planted in either of the above methods, may be suffered to remain in the ground two or three years or more, unremoved; when by their being increased by off-sets into large bunches, each will send up several flower-stalks, and shew a large cluster of flowers, appearing considerably more conspicuous and beautiful than when the flower-stalks rise singly: remark, however, it is proper to take up the bulbs in general every third or fourth year, in order to separate the off-sets, which in that time will be increased so greatly in number, that the bulbs pressing close against one another, the inner ones will be so much compressed and weakened, as greatly to impede their efforts for flowering.

But where these bulbs are intended for sale, they should generally be lifted once a year, or once every two years, otherwise, as by their growing close in clusters pressing against one another, they will be flattened thereby, and rendered unsightly, and less saleable.

The only proper time of year for taking up all the sorts is soon after they have done flowering, when their leaves and flower-stalks assume a state of decay; at which time of lifting the bulbs, separate them all singly, and the smaller off-sets from the larger, reserving the large roots for planting again in the principal compartments, and the smaller may be deposited in nursery beds for a year or two, to gain strength, when they will become proper blowing roots; and may then be taken up at the proper season, in order for planting where wanted.

When the roots are lifted at the above proper season, they may either be planted again directly, or in a month or six weeks after; or may be cleaned and dried, and retained out of

the ground in a dry room, two or three months or longer, if occasion shall require; but, as before suggested, I should advise the principal part to be committed to the earth again in autumn, i. e. in September, October, or November.

Blowing them in Glasses of Water, &c. in Winter, to ornament Rooms.

The *Polyanthos Narcissus*, and the large Jonquills, are also in great esteem for blowing in glasses of water, in rooms, in winter and early in spring, before those in the open ground come into bloom; any of the other species may also be flowered in the same manner; observing to procure such roots as were lifted at the proper season above mentioned.

The glasses for this use are a sort of bottle, of about two or three gill-size, narrow and upright, six or seven inches high, with wide mouths to fit the bulbs, one for each glass; and are sold at all the glass shops. The season for using them is, any time in winter, or early spring, from October or November till February or March: observing to fill them with fresh soft water, so full as the bottom of the bulb may just touch it; so place one bulb in each glass as aforesaid, and place the glasses in any light warm room near the windows where the sun comes: the roots will soon send out fibres downward into the water, and leaves and flower-stalks at top, and flower strong and agreeably in the dead season of winter, and beginning of spring, attended with a delightful fragrance.

The water should always be kept up to the proper height in the glasses, adding an entire fresh supply every three weeks or a month.

We may see many of these bulbous-rooted plants blowed in the above manner, in great perfection, in winter and spring, in the seed-shops in London; particularly the *Polyanthos Narcissus*, and fine Jonquills, Hyacinths, &c.

The same plants may also be brought to early bloom in pots. Plant the bulbs in pots of light rich earth, which place in a warm room, as directed for the glasses, placing them in plates of water occasionally, when the earth wants moistening, and take them out again when moist enough; and thus they will blow at an early season.

But such as have the advantage of stoves, or hot-beds under glasses, need only carry their glasses or pots of bulbs thither, setting the former upon shelves, and plunging the latter

latter into the bark-bed, &c. they will have fine flowers from December till the end of March without much trouble.

We must observe, that to enjoy the pleasure of this winter floral-scene of these kinds, the largest bulbs are always to be chosen, otherwise it will be impossible to compass it with any degree of perfection.

The bulbs made use of for this purpose, although they rarely serve for the same use again, yet they will not be lost, but may be continued in vigour for encrease, provided they are taken out of the glasses or pots as soon as the flowers are gone off, and after cutting off their tops and fibrous roots, plant them in beds of mould to stand till the proper lifting season, in the mean time they will there multiply by off-sets, and thus prove a nursery to supply your pots and glasses.

The prices of the roots of *Narcissus* at the nurseries and seed-shops is different according to the sorts: they are commonly sold by the hundred, or in proportion. The common Daffodils are cheap enough, generally two or three shillings a hundred; and the other uniflorous kinds, both white and yellow sorts, sell at from about three to six shillings per hundred roots; but the *Polyanthos Narcissus* sell at a greater price, generally from ten to thirty or forty shillings per hundred, especially the fine Dutch varieties, some of which often sell from one to eight or ten shillings per single root; the Jonquils are generally from five to ten or twelve shillings per hundred, according to their size and goodness, and whether single or double; and some of the largest double kinds for blowing in glasses, sell at the rate of thirty or forty shillings per hundred: observing of the species of *Narcissus* in general, that if you have different varieties in each parcel, the prices are generally advanced a little in proportion.

Most of the eminent nursery and seedsmen about London import a great variety of the *Polyanthos Narcissus* annually from Holland, the Dutch being famous for raising many new varieties of this species, and of all other curious bulbous-rooted flowers from seed, with which they supply this and other countries, and make us pay well for their industry.

However, after procuring a few roots of each sort, you may with care greatly encrease the stock in two or three years.

Propagation of all the Sorts.

The propagation of all the sorts of *Narcissus*, is effected principally by their abundant off-sets from the roots; also by seed to obtain new varieties.

By Off-sets.—All the sorts encrease plentifully by off-set-bulbs from the main roots annually; and the proper time for separating them is in summer, when they have done flowering, and the leaves and stalks begin to decay, as observed of other bulbous roots; at which time the roots may either be taken up every year or two, to separate the off sets, but should not remain longer unremoved than three years, when each root will be then multiplied by its off-sets into a large cluster, and, as we before noticed, it is necessary to lift them, especially the principal sorts, to divide the increased parts; reserving the main bulbs to plant, as before directed, for the succeeding year's bloom; and the off-sets should be set in nursery-rows, drilled in three inches deep, and six from row to row; to remain to have one or two years growth, when they will have become large bulbs capable of producing flowers in full perfection; and being then taken up at the proper season, may be planted in autumn following, in any place where required.

By Seed.—This mode of propagation is rarely practised to any but the *Polyanthos Narcissus*, and that principally for the sake of new varieties: I would observe, however, that this work of raising them from seed is exceedingly tedious, as it will be often six or seven years before the seedlings will flower in perfection; it is nevertheless practised by many curious florists, more particularly those of Holland, who exceed all the world in their patience and industry in raising seedling bulbous flowers, for encreasing the number of new varieties, which they often sell at a high price; and the following is the method of raising seedlings of the *Narcissus* kind.

The seed ripens in June or July, which sow soon after in pots or boxes of light rich earth, half an inch deep; then place them to have only the morning sun till October, at which time place them in a full sunny situation for the winter, allowing them shelter in severe frosts. In March or April they will come up, give frequent sprinklings of water, and occasional shade from the mid day sun at their first appearance; and as the warm season advances,

advances, move the pots to an eastern aspect, to have only the morning sun till ten or eleven o'clock. In June or July the leaves will decay, when stir the surface lightly, and clear off the decayed leaves, all weeds and mossiness, then sift a little fine mould over the surface, half an inch thick, repeating it again in October or November; and here let them remain undisturbed till the third year, each year repeating the above work; and in the third summer at the decay of the leaves, take up the bulbs, and separate the largest, which plant in beds, by drilling, in rows, five or six inches asunder, and three deep; and the small bulbs you may scatter, mould and all, on the surface of another bed, and cover them two or three inches deep, with fine earth, which after a year's growth may be transplanted in rows, as above.

In these beds let the seedlings remain till they shew flowers, and after the second year's bloom you will be able to judge of their properties, when mark the good sorts; and manage them as directed for the blowing roots.

NECTARIUM, (from *Nectar*, or honey) a part of the corolla forming a sort of appendage to the petals of some flowers, and is of various structures, figures, sizes, and situations; is generally hollow, or with a cavity, and appropriated for containing the Nectar or honey under a fluid-form that oozes from the plant, and is supposed to serve some secret purpose of fructification.

The *Nectarium*, however, although a part belonging to the corolla, is considered distinct from the petals, as differing therefrom in point of structure, form, and size; yet is often of the same texture of the petals, and often of a different nature.

But the *Nectarium* appears in a wonderful variety of forms, &c. in different genera; in some it is united with the petals, in others separate. Its situation is sometimes within, and sometimes withoutside of the corolla; sometimes in the calix, and sometimes on the germen, filaments, and antheræ. In figure, in some sorts it is in form of a tube, in others like a cup or dish; in some it is wide and spreading, often appearing like an additional petal; and in some is very large, equalling the whole corolla in size, and sometimes larger, and very conspicuous; and in some flowers it is very small, frequently appearing like a pore, a point, fibres, &c. in some it assumes a horn like appearance; some-

times its fits close, and in some it is elevated upon a sort of style, or pedunculi, &c. and in a vast variety of other forms.

The *Nectarium* therefore, in point of situation and figure, is exceedingly various in different genera, as before noticed, but is frequently situated at the base of the corolla; sometimes in form of a narrow tube, as in some monopetalous tubular flowers, the lower part or tube being generally found to contain the *Nectar* we formerly mentioned: in many flowers its situation is also at the base, and stretch out behind very conspicuously into a long tube, like a horn or a cock's-spur, as in lark-spur, nasturtium, toad's flax, columbine, balsamine, orchis, &c. sometimes it is situated in the centre of the corolla, and shaped like a cup or a bell, as in *Narcissus*, and in which it is frequently, but erroneously called the cup, in some of which species it is very large and conspicuous: in some genera it is swollen like a bladder, and hollow, as in *cypripedium*, or ladies-slipper, in which it is situated in the midst of the five petals, in which it is of singular structure, very large, and fancied to resemble the shape of a slipper, or wooden shoe. In passion-flowers it is situated in the middle of the corolla, consisting of many short beautiful fibres, disposed in rays, in three series or circular rows round the style, forming a sort of triple crown, exhibiting a singularly curious appearance; which is also the case of the *Nectarii* in many other genera.

When the *Nectarium* is distinct from the petals, it is commonly very irregular, and affords many singular and curious variations.

Any farther description of this striking appendage, or superfluity of the corolla, would be unnecessary in this place, as being so very different in different genera, and both its form and situation is attended to in discriminating the *characters* of the respective genera that are furnished with a *Nectarium*.

The *Nectarium* often furnishes one of the essential marks in discriminating the characters of many genera.

Plants which have the *Nectarium* entirely distinct from the petals, that is, not united with their substance, are commonly poisonous, such are the *aconitum* or monk's-hood, columbine, dog's-bane, hellebore, *asclepias* or swallow-wort, *nigella*, oleander, *narcissus*, *dictamnus albus* or white dittany, and several other sorts.

NEPETA, Nep, or Cat-mint.

The plants are herbaceous perennials for variety in the pleasure-garden, and for medical use; rising with slender branching stems, a foot or two high; garnished with heart-shaped and lanceolate leaves, and the branches terminated by verticillate spikes of monopetalous ringent flowers.

Class and order, *Didynamia Gymnospermia*.

Characters.] CALIX, is monophyllous, tubulous, and five-parted at top. COROLLA, is monopetalous, with a cylindric incurved tube, ringent or gaping at top; the upper lip roundish, emarginated, and erect, the under one large, roundish, concave, and entire. STAMINA, two long and two short filaments, terminated by incumbent antheræ. PISTILLUM, a quadrifid germen, slender style, and bifid acute stigma. PERICARPIUM, none, the seeds lodged naked in the calix.

There are twelve or fourteen species, but not more than one common in the English gardens, viz.

NEPETA *Cataria*.

Cataria, or Common Cat-mint.] Hath a creeping perennial root; many upright square stems, branching two feet high; heart-shaped, dentated-serrated, opposite leaves, hoary underneath, each on a long foot-stalk; and the branches terminated by whorled spikes of white ringent flowers, the under verticilli having short pedicles: flowering in June.

Varieties.] Larger Cat-mint—smaller Cat-mint—narrow-leaved—blue-flowered—purple-flowered.

This species and varieties have great fragrance, partaking of mint and penny-royal; is cultivated in gardens both for medicine, and to effect variety in the herbaceous collections,

The name *Cataria*, or Cat-mint, originates from the circumstance of the cats being so remarkably fond of the plant, that they eagerly repair to it, roll themselves thereon, bite and tear it to pieces, chewing it in their mouths, and often in a short time entirely destroy the plants. It has been by some observed, that if you raise this plant from seed, and it remains where sowed, the cats will not meddle with it, but if by slips, or if transplanted, they will soon destroy it. Whence proceeds the saying—

If you set it, the cats will eat it;

If you sow it, the cats will not know it.

This, however, does not always hold good invariably.

It grows naturally in England by hedgesides, and on the sides of banks, but it has been long admitted an inhabitant of gardens, both for its singularity, and for medical use.

Its propagation is by seed, by parting the roots, and by slips or cuttings.

By Seed.—Sow it either in autumn, or early in spring, in any bed or border of light earth, and rake them in; and when the seedlings are two or three inches high, plant them out in nursery-beds to remain till autumn, and then transplant them where they are remain.

By Parting the Roots.—In autumn or spring divide the roots into slips, which, being planted separate, will soon become good plants.

By Slips or Cuttings of the Branches.—In April, May, or June, slip or cut off a quantity of young shoots, plant them in the shade, and supply them with water, they will become good plants by autumn.

NERIUM, *Oleander*, or Rose-Bay.

This genus comprehends beautiful evergreen flowering shrubs for the green-house and stove, of upright branchy growth, adorned with long, spear-shaped, stiff, ever-green leaves; and large monopetalous, funnel-shaped, quinquepartite, nectarious flowers, in clusters from the sides and ends of the branches of very ornamental appearance.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, is acutely five-parted, small and permanent. COROLLA, is monopetalous and funnel-shaped, a short cylindric tube, having the upper part large and divided into five broad, obtuse, oblique segments, and a nectarium terminating the tube, being divided into many hair-like parts, arranged in a coronated form. STAMINA, five very short, awl-shaped filaments, terminated by arrow-pointed, connivent antheræ, ending in long threads. PISTILLUM, a roundish bifid germen, cylindric style, and truncated stigma. PERICARPIUM, two long, taper, acuminate, univalvular pods, furnished with numerous oblong seeds, placed *imbricatum*, and crowned with down.

There are about four species, but not more than one common in the English gardens, which is the most beautiful of all the sorts, and admits of several elegant varieties.

NE-

NERIUM, *Oleander*.

Common Oleander.] Rises with an upright woody stem, branching six or eight feet high, having a purple or green bark in different sorts; long, spear-shaped, stiff-leaves, from about three to five or six inches long, and one broad, placed ternate or by threes round the branches; and at the axillas and ends of the shoots large loose bunches of very ornamental flowers of different colours and properties in the varieties. Flowering in July and August.

Varieties.] Red-flowered Oleander—scarlet-flowered—white-flowered—broad-leaved double-flowered—striped double-flowered—striped-leaved.

Some of these varieties are in some authors ranged as different species; they, however, are only varieties of the above species of *Nerium Oleander*.

This species and varieties are not only fine ever-greens, but produce large clusters of exceeding ornamental flowers: the double-blossom kinds in particular have superior beauty, the flowers being very large, and the corolla multiplied in several series, having some resemblance to middling double roses; are numerous, very conspicuous, and fragrant, continuing in succession a month or two in full lustre.

They are exotics from the island Crete and India, but all the varieties are hardy enough to succeed in the open air here in summer, and in a green-house in winter.

Observe, however, the double flowered kinds being rather of a more tender temperature than the singles, that they generally flower the most perfectly when indulged with a stove, even if only placed therein, or in a glass-case, about the time of year they are expected to make an effort for flowering, and their flowers will continue longer in beauty; often exhibiting a succession of elegant flowers from July until October.

Let all the sorts be potted in light rich compost, and move them into the green-house, &c. in autumn, at the approach of cold weather. Supply them with water once a week in winter, or oftener according as they shall seem to require, but give more frequent waterings in summer, in proportion to the heat and drought of the season; and according as they advance in size, shift them into larger pots of fresh mould: their further general culture is as directed for other shrubby green-house exotics.

These plants are cultivated at all the nurseries for sale.

Their Propagation.

Their propagation is by layers, cuttings, and by suckers from the root.

By Layers.—This may be performed any time from March until May, but the earlier the better; and the youngest lower branches are to be chosen; which lay by slit-laying: give plenty of water all summer as they shall require, and they will be mostly rooted by the following autumn; but by plunging the pots in which they are layed, in a bark-bed, the rooting of the layers may be greatly forwarded: when properly rooted transplant them into separate pots.

By Cuttings.—In spring or the early part of summer, take off cuttings of the young shoots, five or six inches long and plant them in large pots of rich mould, which place under glasses, and give water and shade occasionally: but if plunged in a bark bed it will promote and forward their rooting more effectually.

By Suckers.—Suckers often arise from the bottom, sometimes furnished with roots, but if not, give each a small slit at the lowest part; then apply fresh mould around it, and fibres will be emitted by the end of summer; then take them off and pot them separately.

NICOTIANA, Tobacco plant.

This genus of plants are tall herbaceous annuals of America, where they are cultivated in vast quantities for their leaves, of which is prepared that well-known commodity called *Tobacco*; and are raised here in many gardens for variety, which they effect most agreeably in their upright growth, and noble large foliage; they rising each with an upright strong stem, from three to six or eight feet high, branchy at top; ornamented with large oblong simple leaves, from about ten or twelve inches to a foot and a half long, and proportionally broad; and monopetalous infundibuliforme flowers terminating all the branches plentifully in loose bunches.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, is monophyllous, five-parted and permanent. COROLLA, is monopetalous, infundibuliforme, having a long tube, spreading above, there terminating in five parts. STAMINA, five long subulate filaments, and oblong antheræ. PISTILLUM, an oval germen, long slender style, and

and capitated emarginated stigma. PERICARPIUM, an oval, furrowed, bilocular capsule, opening at top, and numerous kidney-shaped seeds.

Tobacco was introduced into Europe in the year 1560, discovered first in the island Tobago in America, and by the natives is called *Tobac*, hence the English appellation Tobacco; but the generic name *Nicotiana* is derived from one Mons. Nicot, who first introduced the seed of the plants into the European gardens.

There are about seven species, but the most remarkable sorts known in the English gardens, are the two following.

¹NICOTIANA *Tabacum*.

Tabacum, or Common Virginia Tobacco.] Hath fibrey roots; an upright, round, strong stem, rising from about five or six to eight or nine feet high, dividing near the top into branches; very large, spear-shaped oval, sessile, decurrent leaves, from ten to eighteen inches long, and half as broad; and the stem and branches terminated by loose panicles of acute pale-red flowers.

Varieties.] Great broad-leaved—narrow-leaved.

²NICOTIANA *Rustica*.

Rustic Hardy English Tobacco.] Hath a fibrey root; an upright firm stem, rising three or four feet high; large, oval, entire leaves, having foot-stalks; and the stem terminated by small loose panicles of yellowish-green obtuse flowers.

These plants are of the annual tribe; natives of most parts of America, but tolerably hardy, so as to prosper in our gardens as in their native soil: the first sort, however, is rather a little tender while young, requiring generally to be raised and forwarded in a hot-bed until May; but the second species is exceeding hardy, and was the sort first introduced into the English gardens; and being so hardy as to ripen great plenty of seeds freely every year, and that from the scattered or self-sown seeds in autumn; the plants rise plentifully the following spring without trouble, as if natives of England: from which circumstances it is often called English Tobacco. The first species, however, is the finest plant, both in its procerity of growth, largeness of the leaves, and beauty of its flowers.

They flower here in July and August: the flowers are collected into clusters, each flower is of one funnel-shaped petal, spreading and five-parted above; continuing in succession

until the end of summer; succeeded by ripe seeds in autumn.

The seeds of these plants are very small, generally about 1000 in each capsule, and the whole produce of a single plant is estimated at 360,000.

With respect to the merit of these species in this country as garden-plants, they are cultivated in many curious gardens, as ornamental annuals for the pleasure ground, but more particularly the first species, which obtaining a fine majestic stature, adorned with most luxuriant leaves, and large clusters of delicate red flowers terminating all the shoots; they in the whole exhibit an elegant appearance in autumn. The second sort has also merit enough to recommend it for admittance in a collection in assemblage with the others, &c. to effect a greater variety. Both the sorts are also cultivated in some gardens for use, the leaves are the useful part; are in perfection early in August, just when they come into flower, and before the under-leaves begin to wither.

As both the species perish annually in winter, a fresh supply must be raised every spring.

Their Propagation.

Their propagation is by seed annually in March or April, the first sort in a hot-bed, the second in the natural ground.

First Sort.—This being rather a little tender whilst young, in order to have it brought to perfection as soon in the summer as possible, it is proper to sow the seed in a moderate hot-bed in March or April, covering them near a quarter of an inch deep: they will soon come up; allow them fresh air daily, and occasional waterings; managing them as directed for annuals of similar temperature, such as *chrysanthemum*, African marigolds, &c. and in May or early in June, when the seedlings are from about three to six inches high, plant them out in moist weather, in the open ground: those designed for ornament, plant singly in the different compartments of the pleasure-garden, and those intended for use may be set in rows any where, three feet asunder; as soon as planted give a good watering, and repeat it occasionally till the plants have got fresh root; and they will soon set to growing luxuriantly, so as to acquire their full stature in August, and continue in beauty till October.

Second

Second Sort.—This sort being of a hardier nature, you may sow the seeds in any bed or border in spring, and rake them in lightly; they will readily come up: when the plants are three inches high, plant them out where they are to remain; or may sow the seed in patches to remain, and thin the plants to one in each patch.

NIGELLA, (*Nigella*) Fennel-flower, or Devil-in-a-Bush.

This genus consists of hardy, herbaceous, annual flowers for the pleasure-garden; rising with upright branchy stalks a foot and a half high, adorned with multifid or finely-divided leaves, resembling those of fennel or dill; and with all the branches terminated by large spreading pentapetalous flowers singly; and as some of the plants being of bushy growth, and each flower having five or ten long horn-like styles and capsules, and which in some species are closely surrounded at the sides and top, by a large, leafy, finely-divided involucre, forming a sort of bush as it were around them; hence originated the strange name, Devil-in-a-Bush.

Class and order, *Polyandria Pentagynia*.

Characters.] CALIX, none, only some long, finely-multifid, floral leaves, appearing like a perianthium, or a sort of involucre. COROLLA, five oval, plane, obtuse, spreading petals, contracted at the base; and eight very short bilabiated nectaria placed in a circle. STAMINA, numerous short subulate filaments, and compressed erect antheræ. PISTILLUM, five or ten oblong, convex, erect germina, ending in the same number of very long, awl-shaped, revolute, permanent styles, and stigmas growing longitudinally. PERICARPIUM, five or ten oblong, compressed, acuminate capsules, connected by their inner side, and filled with numerous angular rough seeds.

There are about five species, all annuals, remarkable for some having five styles, and some ten.

¹NIGELLA *Damascene*.

Damascene Five-styled Nigella.] Rises with an upright stem, branching a foot and half high; garnished with finely-multifid leaves, the segments long, very narrow and numerous; and large flowers surrounded by a long leafy involucre; and hath five horn-like styles.

Varieties.] Common pale-blue-flowered—with white flowers—with double flowers, of both kinds.

²NIGELLA *Hispanica*.

Spanish Ten-styled Blue Nigella.] Rises with an upright branchy stem, a foot and a half high; garnished with multifid leaves, having broader segments; and each branch and shoot terminated by one very large blue flower, having ten styles of equal length with the corolla.

Variety.] With double flowers.

³NIGELLA *Sativa*.

Sativous Five-styled, White, Egyptian, Nigella.] Rises with an erect branchy stem, about a foot and a half high; shorter, multifid, somewhat-hairy leaves; and each branch terminated by one large white flower, having five styles; succeeded by roundish prickly capsules.

Varieties.] Double-flowered—dwarf-stalked—sweet-scented.

⁴NIGELLA *Orientalis*.

Oriental Ten-styled Yellow Nigella.] Rises with an upright stem, branching a foot and a half high; long finely-multifid leaves; and at the ends of the branches small yellow flowers, having ten styles, longer than the corolla.

⁵NIGELLA *Arvensis*.

Arvense, Five-styled, Blue, German Nigella.] Rises with a slender branchy stem, about a foot high; very finely-multifid leaves; and pale-blue naked flowers singly, having entire petals, and five styles; succeeded by large turbinated capsules.

All these five species are annual, rising from seed in spring, and totally perish in autumn, after having flowered and perfected their seeds.

They all flower here in July and August, the flowers are moderately large, universally hermaphrodite, and consist each of five oval plane petals; very long, revolute, permanent styles; succeeded by several oblong compressed capsules, all united, each terminated by the permanent style like horns, generally bending different ways; and each capsule filled with numerous seeds, ripening in autumn.

The plants are all very hardy, and grow freely any where in the open compartments.

All the sorts may be employed in the pleasure-garden, as plants of variety and ornament in the collection of hardy annuals; but the first two sorts, and varieties, are the most commonly known in the English gardens, and are generally the most ornamental in the size and beauty of their flowers: observing of all the sorts,

forts, that the double flowered varieties are to be preferred for general culture; all of which being disposed in patches, sowing the seeds at once where they are to remain to flower, they will exhibit a pretty variety in assemblage with other annuals.

Their Propagation, &c.

Their propagation is by seed in the open borders, &c. in March and April: or if some are sowed in autumn, and one or two sowings performed in spring, the autumnal-sowed plants will flower strong and earlier, and will be succeeded in bloom by the spring-sowings, whereby the season of flowering will be greatly prolonged.

Sow the seed in patches about the borders, at once where you design they shall flower, for they rarely succeed by transplantation, covering it near half an inch deep; and when the plants are come up an inch or two high, thin them where too close, to three in each patch, and keep them clean from weeds is all the culture they require; and they will all flower at the proper season, and produce plenty of seed for future propagation.

As all the sorts perish totally in winter, a fresh supply must be raised annually from seed, as above.

NURSERY, a most useful district of gardening, appropriated for the raising and nursing all sorts of trees, shrubs, and herbaceous plants to a proper growth, for supplying and recruiting the different gardens, orchards, plantations, &c.

In the Nursery-garden are raised all the different sorts of fruit-trees, and fructiferous shrubs, by the methods directed for each sort under their proper genera, nursing and training them up to a proper size and growth for planting in the garden or orchard, where they are finally to remain to produce their fruit.

Likewise in the Nursery is raised the vast train of forest-trees, hardy ornamental trees, and shrubs in general, both deciduous and ever-greens of all those kinds, and training them up to a proper size for the purposes for which they are designed in the plantations and pleasure ground.

And in the Nursery may also be raised all the sorts of hardy herbaceous plants, both fibrous-rooted, bulbous, and tuberous-rooted kinds, for adorning the pleasure-garden, medicinal use, &c.

All sorts of the above kinds may be readily raised together in the same Nursery in separate compartments.

A Nursery thus furnished with the different sorts of all kinds of trees, shrubs, and herbaceous plants, will prove an inexhaustible source of accommodation both for private and public use.

The raising or propagation of the numerous kinds is performed by various methods, as by seed, suckers, layers, cuttings, slips, off-sets, parting the roots, grafting, budding; each of which methods as directed under their proper heads; as also in the respective articles under their proper genera: and after being raised by either of the above methods, and stationed in Nursery-rows, they are to remain until they have acquired a proper growth for their respective uses, then to be transplanted into the garden, orchard, plantation, &c. where they are designed finally to remain, to effect the several purposes for which they are calculated, either for use, ornament, or variety; observing, that as a recruit of some or other of the various sorts will be required to be drawn off every year, to supply the different gardens and plantations, a fresh supply of young plants should also be raised accordingly every year in the Nursery, of most of the various kinds, so as to have this district always fully stocked with all kinds in several different degrees of growth; some in seed-beds, others transplanted in Nursery rows; some one year, others two, three, or several years: all of which should be well attended to, both in private and public Nurseries, that there may be a sufficiency of plants of all sorts for furnishing every different department of gardening as they shall be occasionally wanted.

In the public Nursery-gardens they have also convenient green-houses, glass-cases, and stoves, with their proper appendages, for raising the tender exotics from the warmer parts of the world; each of which departments are always stationed in the warmest and most sunny situation, having their front directly facing the south, to have all possible benefit from the sun's influence; and each principal department having its different appendages, as aforesaid, which are smaller departments of frame-work, sashed and glazed, either adjoining to the main ones, or detached; serving as seminaries or Nurseries for raising and nursing the various tender plants to a proper growth for furnishing the other larger conservatories.

Thus

Thus a Nursery ground furnishing all sorts of plants of different temperatures, will prove a most valuable department of gardening, and its various growths will afford the most agreeable source of variety at all seasons, which to many will appear as ornamental and desirable as the most elegant pleasure-ground or flower-garden.

It's Extent, Soil, Situation, &c.

With respect to the proper extent or dimensions of a Nursery, whether for private use, or for public supply, it must be according to the quantity of plants required, or the demand for sale: if for private use, from a quarter or half an acre to five or six, may be proper, which must be regulated according to the extent of garden-ground and plantations it is required to supply with the various sorts of plants; and if for a public Nursery, not less than three or four acres of land will be worth occupying as such, and from that to fifteen or twenty acres, or more, may be requisite, according to the demand, though some occupy forty or fifty acres in Nursery-ground.

In the neighbourhood of London, for eight or ten miles round, there are a great number of extensive public Nurseries, most beautifully furnished with a prodigious variety of all sorts of trees, shrubs, and herbaceous plants, of many different degrees of growth, for supplying noblemen and gentlemen's gardens and plantations, for some hundreds of miles distant at home and abroad; as also all sorts of seeds. Most of which Nurseries are also furnished with all proper green-houses, glass-cases, stoves, &c. for the raising all kinds of curious tender exotics for public supply.

With regard to soil for a Nursery, the nature and quality of this, without all dispute, requires our particular attention. The Nursery-men generally prefer a loamy soil of a moderately-light temperament, if possible, such as in most of the Nursery-grounds around London: however, a Nursery may be of any fat moderately light land, that is fifteen or eighteen inches depth of good working staple, but if two or three spades deep it will be the greater advantage; and where there is scope of ground to chuse from, always prefer that where there is a good depth, and naturally rich or fat soil, for the soil of a Nursery cannot be too good, notwithstanding what some advance to the contrary; for if the soil prove poor and lean, the plants raised thereon

will be languid, weak, and stunted; and no remedy, how artful soever, will be able to rectify their constitution, especially all the tree-kinds: whereas those raised in a good fat soil always assume a free growth, and advance with strength and vigour. It is not absolutely requisite, however, that the soil should be exceedingly rich, nor over carefully manured, a medium between the two extremes is best. A good fresh fat soil, such as any good pasture, which having the sward trenched to the bottom, is excellent for the growth of trees; any good fat soil of corn-fields is also extremely proper; or any other good soil of the nature of common garden-earth is also very well adapted for a Nursery.

As to situation; if this is rather somewhat low it will be the better, because it is naturally warmer, and more out of the power of cutting and boisterous winds than a higher situation; though if it happens where some parts of the ground is high and some low, it may be an advantage, the better to suit the nature of the different plants. It is also of singular advantage to have a Nursery-ground fully exposed to the sun and free air, and, if possible, where there is the convenience of having water for the occasional watering of seedlings, and some newly transplanted plants.

And as to a Nursery for private use, with regard to its place of situation, respecting the other garden districts, that, where there is room, it may either be entirely detached, or may be somewhat contiguous to the outer boundaries of the shrubbery plantations of the pleasure-ground, and so contrived as to lead insensibly into it by winding walks, so as to appear part of the garden.

It's Fences, Preparing and Dividing the Ground.

A fence round the whole ground is necessary: this may either be a hedge and ditch, or a paling; the former is the cheapest, and in the end the most durable; though in some places where hares and rabbits abound, paling fences at first are eligible, for preserving the Nurseries from the depredations of those animals, which often do great mischief to the young plants, by barking and cropping them: a good hedge-and-ditch-fence, however, may be made very effectual against the inroads of both men and brutes; and the most eligible plants for this purpose is the haw-thorn; for the method of raising of which, and forming a

proper hedge of them, see *CRATÆGUS Oxyacantha* and *HEDGES*.

The ground must then be all regularly trenched one or two spades deep, according as the natural depth of the soil will admit, for by no means dig deeper than the natural good soil, let it be either one, one and a half, or two spades deep; observing the same general method as directed under the article *Digging by Trenches*; see *DIGGING*.

Then, having trenched the ground, proceed to divide it by walks into quarters, and other compartments; a principal walk should lead directly through the middle of the ground, which may be from five to eight or ten feet wide, according as it shall seem proper for use or ornament, having a broad border on each side: another walk should be carried all round next the outward boundary, four or five feet wide, leaving an eight or ten-foot border next the fence all the way; then may divide the internal part by cross walks, so as to form the whole into four, six, or eight principal divisions, which are commonly called quarters.

Sowing and Planting this Department with the proper Seeds, Plants, &c.

One or more of the divisions must be allotted for a seminary, i. e. for the reception of all sorts of seeds, for raising seedling plants to furnish the other parts; therefore divide this seminary-ground into four-feet-wide beds, with foot-wide alleys at least between bed and bed: in these beds should be sowed seeds, &c. of all such trees, shrubs, and herbaceous plants as are raised from seed; and which seeds consist of the various sorts of kernels and stones of fruit, to raise stocks for grafting and budding; seeds of forest-trees, ornamental trees, shrubs, &c. and seeds of numerous herbaceous perennials, both of the fibrous-rooted and bulbous-rooted tribe; the sowing season is both spring and autumn, according to the nature of the different sorts, which is fully illustrated under their proper genera; and when the young tree and shrub seedling-plants so raised, are one or two years old, they are to be planted out in Nursery-rows into the other principal division; but many kinds of herbaceous plants require to be pricked out from the seed-beds, when but from two to three or four months old, as directed for each under their own respective heads. On the other hand, most kinds of

bulbous seedlings will not be fit for planting out in less than one or two years.

Another part of the Nursery-ground should be allotted for stools of various trees and shrubs, for the propagation by layers, by which vast numbers of plants of different kinds are propagated. These stools are strong plants of trees and shrubs, planted in rows three or four feet distance every way, and such of them as naturally rise with tall stems, are, after being planted one year, to be headed down near the ground, to force out many lower shoots conveniently situated for laying. See *LAYERS* and *STOOLS*.

The other principal divisions, therefore, of the Nursery-ground, is for the reception of the various sorts of seedling-plants from the above seminary-quarters; also for all others that are raised from suckers, layers, cuttings, &c. there to be planted in rows from one to two or three feet asunder, according to their natures: observing to allow the tree and shrub-kinds treble the distance of herbaceous perennials. Of the tree and shrub kinds some are to be planted for stocks to graft and bud the select sorts of fruit-trees upon, and other choice plants, which are usually propagated by those methods; others are trained up entirely on their own roots without budding and grafting, as in most forest and other hardy tree kinds; as also almost all the sorts of shrubs: particulars of all which are exhibited, each under its proper genus. Here they are to remain to have two, three, or several years growth, according as they shall require for the several purposes for which they are designed in their future situations in the garden, &c. which is directed in their respective cultures.

The Methods and Seasons for Raising and Transplanting the various Plants of this Department.

With regard to the manner of performing the various methods of propagation for raising the numerous Nursery-plants, is fully exhibited also under the following heads, in the course of this work: *sowing seeds—layers—cuttings—suckers—slips—off-sets—parting roots—grafting—inoculation*. And the sorts that are usually propagated by either of those methods, are pointed out under their several respective heads, with particular directions of the several ways each method is performed on the different kinds.

The season for performing the works of sowing, planting, &c. is different in different kinds,

kinds, but autumn and spring are the principal seasons.

Some sorts require to be sowed in autumn, others not till spring, which is particularly explained for the various sorts under the articles themselves.

And as to planting or transplanting, the principal season is from October until March, or even until April for tender kinds, especially many of the ever-green tribe; but all hardy trees and shrubs may be transplanted any time in winter, in open mild weather from October until March, as just observed; and for the tender kinds of ever-greens, &c. early in autumn, or not till settled weather in spring, is the proper time to remove these sorts.

But as to hardy herbaceous fibrous-rooted plants, they may be transplanted almost any time in autumn or spring; even many sorts in summer, when planting them out from the seminary: observing, however, autumn and spring is the proper planting-season for older or larger plants; and which are also the only proper seasons for dividing or slipping the roots of all these kind of plants for encrease.

And for bulbous-rooted kinds, and all such tuberous roots whose leaves decay in summer, the proper season for planting or transplanting them is from May or June until the beginning of August, when their flower-stalks decay, which in some sorts happens early and some late in the summer; but as soon as it happens in the different sorts, is the only proper time to remove all those kind of plants when necessary, as also to separate their off-sets for encrease; and which may either be planted again directly, or kept out of ground one, two, or several months, though it is proper to plant the principal part again in autumn, unless where any is to be retained for sale.

Succulent perennials may be transplanted almost any time from March or April until August or September, which is the best season for removing these kinds, and most kinds of succulent cuttings, succeed best when planted in summer.

General Mode of arranging the Plants of this Department.

In the distribution of all the various sorts of plants in in the Nursery, let each sort be separate: the fruit-trees should generally occupy spaces by themselves; the forest-trees, &c. should also be stationed together; all the shrub-kind should also be ranged in separate com-

partments; allot also a place for herbaceous perennials; a warm place should likewise be allotted for the tender kinds, and inclosed with yew hedges, or a reed hedge, &c. in which compartments you may station all such plants that are a little tender whilst young, and require occasional shelter from frost, yet are not so tender as to require to be housed like green-house plants, &c. so that in such compartments there may also be frames of various sizes, either to be covered occasionally with glass-lights, or with mats, to contain such of the more choice of the above tender kinds in pots, to be nursed up a year or two, or longer, with occasional shelter, till hardened gradually to bear the open air fully.

The arrangement of all the sorts in the open grounds, must always be in lines or Nursery-rows, as we formerly observed, to stand till arrived at a proper growth for drawing off for the garden and plantations; placing the fruit-tree stocks, &c. for grafting and budding upon, in rows two feet asunder, if for dwarfs; but standards two feet and a half, and a foot and half in the lines (see STOCKS); though after being grafted and budded, they then commencing fruit-trees, &c. that if they are to stand to grow to any large size, they should be allowed the width of a yard between the rows. Forest-trees should also be placed in rows from two to three feet asunder, and half that distance in the rows; varying the distance both ways according to the time they are to stand: the shrub kind should likewise be arranged in rows about two feet asunder, and fifteen or eighteen inches distant in each line; and as to herbaceous plants, they should generally be disposed in four-feet-wide beds, in rows from six to twelve or eighteen inches asunder, according to their nature of growth, and time they are to stand.

By the above arrangement of the various sorts of hardy trees, shrubs, and herbaceous plants, in rows at those small distances in the Nursery, a prodigious number of plants are contained within a narrow compass, which is sufficient room, as they are only to remain a short time; and that by being thus stationed in a little compass, they are more readily kept under a proper regulation for the time they are to remain in this department.

But in the public Nurseries they often plant many kinds of seedling-trees and shrubs in much closer rows at first planting out, than the distances above prescribed, not only in order to husband the ground to the best advantage, but by standing closer, it encourages the

the stem to shoot more directly upward, and prevent them expanding themselves much any where but at top, as for instance, many sorts of ever-greens that are but of slow growth the first year or two, such as the pine-trees, firs, and several others; which the Nursery-gardeners often prick out from the seminary, first into four-feet-wide beds, in rows lengthways, six inches asunder; and after having one or two years growth here, transplant them in rows a foot asunder; and in a year or two after give them another, and final transplantation in the Nursery, in rows two or three feet asunder, as observed above; and by these different transplantings, it will encourage the roots to branch out into many horizontal fibres, and prepare them better for final transplantation, which is the more particularly necessary in several of the pine and fir kinds, and several other ever-greens, as is more fully exhibited under their proper genera.

With respect to the different methods of planting the various sorts of Nursery-plants, after being raised either by seed, layers, cuttings, &c. it is performed in several ways to different sorts; some are pricked out by dibble, others are put in by the spade, either by trenches, flitting-in, trenching, or holing; and some are drilled in by a spade or hoe.

As to most of the tree and shrub-kind, sometimes the young seedling-trees and shrubs are pricked out from the seminary by dibble; sometimes they are put in by the spade in the following methods: first, having set a line to plant by, strike the spade into the ground with its back close to the line, and give another stroke at right angles with it; then set a plant into the crevice made at the second stroke, bring it close up into the first-made crevice even with the line, and press the mould close to it with the foot; then proceed to plant another in the same way, and so proceed till all is planted. A second method is for plants with rather larger roots: strike the spade down with its back close to the line, as aforesaid, and then with a spade cut out a narrow trench, close along the line, as practised in planting box-edgings (see *Buxus*), making the side next the line perfectly upright; then placing the plants upright against the back of the trench close to the line, at the proper distances, before mentioned; and as you go on, trim in the earth upon their roots: and when one row is thus planted, tread the earth gently all along close to the plants; and then proceed to plant another row. A second method of planting-out small

tree and shrub plants is, having set the line as above, then turning the spade edgewise to the line, cast out the earth of that spit, then a person being ready with plants, set one in the cavity close to the line, and directly taking another such spit, turn the earth in upon the roots of the plant, and then placing another plant into the second cut, cover its roots with the earth of a third spit, and so on to the end: but sometimes when the roots are any thing larger, holes are made along by the line wide enough to receive the roots freely every way, so covering them in, as above, as you go on: observing always to press the earth gently with the foot close to the roots, and close about the stems, to settle the plants firmly in their proper position.

Herbaceous fibrous-rooted plants are, for the most part, planted with a dibble, except when the roots are large and spreading, or such as are removed with balls of earth; then they are more commonly planted by holing them in with a garden trowel, or small spade.

Bulbous and tuberous-rooted plants, such as lilies, tulips, anemones, ranunculas, &c. are very commonly planted with a dibble, but many sorts may also be drilled in with a hoe, see *DRILL-SOWING*, &c. These sorts are also sometimes planted as follows: rake or trim the earth from off the top of the beds from about three to four or five inches deep, into the alleys, then place the roots in rows upon the surface, and immediately cover them with the earth which was drawn off into the alleys for that purpose, spreading it evenly over every part, so as to bury all the roots an equal depth.

But as to the tender kinds of exotic-plants that require occasional shelter whilst young, many of them should be potted, in order for moving to a warm situation in winter, or some into frames, &c. to have occasional shelter from frost, by glasses or mats, as they shall require; hardening them, however, by degrees to bear the open air fully in the Nursery the year round.

And the most tender kinds that require the aid of a green-house and stove, must all be potted, and placed among the respective plants of those conservatories. See *GREEN-HOUSE* and *STOVE PLANTS*.

General Culture of the Plants of this Department.

With respect to the management of the various hardy Nursery-plants;

Those

Those designed as stocks for fruit-trees, should have their stems generally cleared from lateral shoots, so as to form a clean straight stem, but never to shorten the leading shoot, unless it is decayed, or becomes very crooked, in which case it may be proper to cut it down low in spring, and it will shoot out again; training the main shoot for a stem, with its top entire for the present, till grafted or budded; and as to the grafting and budding them, that work is fully directed under these articles, and their general method of training, whether for dwarfs or standards, is also particularly exhibited under those two heads, and in the respective genera of the various sorts.

Forest-trees should also be encouraged to form straight clean stems, by occasional trimming off the largest lateral branches, which will also promote the leading top-shoot in aspiring farther in height; always suffering that part of each tree to shoot at full length, that is not to top it, unless, however, where the stem divides into forks, to trim off the weakest, and leave the straightest and strongest shoot or branch, to shoot out at its proper length to form the top, as above.

The different sorts of shrubs may either be suffered to branch out in their own natural way, except just regulating very irregular growths; or some may be trained with single clean stems, from about a foot to two or three high, according as you shall think proper with respect to the sorts or purposes for which you design them in the shrubbery; but many shrubs appear the most agreeable when permitted to shoot out laterally all the way, so as to be branchy or feathered to the bottom.

All the fruit-trees, as soon as grafted or budded, should each species have all its different varieties numbered by placing large flat-sided sticks at the ends of the rows, for which purpose many of the London Nursery-men use the spokes of old coach-wheels, or any thing about that size of any durable wood, painting or marking the numbers thereon, 1, 2, 3, &c. to different sticks, entering the numbers in the Nursery-book, with the name of the varieties to which the number-sticks are placed; whereby you can at all times readily have recourse to the sorts wanted.

The same method may be practised to any other trees, shrubs, or herbaceous plants, especially the varieties of particular sorts, when they are numerous, such as in many of the flowery-tribe, as auriculas, carnations, tulips, anemonies, ranunculas, and the like.

With respect to watering the Nursery-plants; this may be very requisite in dry hot weather in spring and summer, to seed-beds and tender seedling-plants, while young, and when first planted out till they have taken good root; also occasionally to new-layed layers, and newly-planted cuttings in dry warm weather; but as to hardy trees and shrubs of all sorts, if planted out at the proper time, that is, not too late in spring, no great regard need be paid to watering, for they will generally succeed very well without any: indeed where there is but a few, you may if you please water them a little, if it proves a very dry spring in April and May; but where there are great plantations it would be an almost insupportable fatigue, and great expence; as in many public Nurseries, where they each winter or spring plant out fifty or sixty thousand trees and shrubs, and in some double those numbers.

Every winter or spring, the ground between the rows of all sorts of transplanted plants in the open Nursery-quarters must be digged; this is particularly necessary to all the tree and shrub-kind that stand wide enough in rows to admit the spade between; which work is by the Nursery-men called *turning-in*; the most general season for which work is any time from October or November until March, but the sooner it is done the more advantageous it will prove to the plants. The ground is to be digged but one spade deep, proceeding row by row, turning the top of each spit clean to the bottom, that all weeds on the top may be buried a proper depth to rot: this work of *turning-in* is a most necessary annual operation, both to destroy weeds, and to encrease the growth of the young Nursery-plants.

In summer be remarkably attentive to keep all sorts clean from weeds; the seedlings growing close in the seminary-beds must be hand-weeded, but the plants of all sorts that grow in rows wide enough to introduce an hoe: this will prove not only the most expeditious method of destroying weeds, but by loosening the top of the soil, it will prove good culture in promoting the growth of all kinds of plants: always perform this work of hoeing in dry weather, in due time before the weeds grow large, and you may soon go over a large space of ground, either with a large drawing-hoe, or with a scuffling hoe, as you shall find the most convenient. See HOE and HOEING.

According as any quarter or compartment of the Nursery-ground is cleared from plants, others must be substituted in their room from the seminary; but the ground should previously be trenched and lie some time fallow, to recruit or recover its former vigour; giving it also the addition of manure, if it shall seem proper; and after being trenched in ridges, and having the repose only of one winter, or summer, or a year at most, it will sufficiently recover its vegetative force, and may be planted afresh.

It will be of advantage to plant the ground with plants of a different kind from those which occupied it before.

The tender or exotic plants of all kinds that require shelter only from frost, whilst young, as we formerly mentioned, and by degrees become hardy enough to live in the open air, should, such of them as are seedlings in the open grounds, have the beds arched over with hoops, or rods, at the approach of winter, in order to be sheltered with mats in severe weather; and those which are in pots, either seedlings or transplanted plants, should be removed in October in their pots to a warm sunny situation sheltered with hedges, &c. placing some close under the fences facing the sun, where they may have occasional covering of mats in frosty weather; others that are more tender may be placed in frames, to have occasional covering either of glass-lights or mats, &c. from frost; observing of all those sorts here alluded to, that they are gradually to be hardened to the open ground, and need only be covered in frosty weather; at all other times let them remain fully exposed, and by degrees as they acquire age and strength inure them to bear the open air fully; so as when they arrive at from two or three to four or five years old, they may be turned out into the open ground. The sorts requiring this treatment, are always pointed out under their proper heads, in their respective genera.

The green-house kinds of all sorts, or such as require constant shelter in winter, are to be managed as directed under the article GREEN-HOUSE PLANTS.

And the hot-house or stove-plants, or such as require constant shelter all the year, together with the aid of artificial heat, are to be managed as exhibited under the article STOVE PLANTS.

NYCTANTHES, Arabian Jasmine.

This genus consists of shrubby, ever-green, very flowery exotics of the Indies, for the stove collection; rising with shrubby durable stems,

branching ten or twelve feet high; adorned with heart-shaped, oval, and spear-shaped, entire leaves; and numerous monopetalous, hypocrateriforme, eight-parted, white, very fragrant flowers in clusters at the sides and ends of the branches.

Class and order, *Diandria Monogynia*.

Characters.] CALIX, is monophyllous, acutely eight-parted, and permanent. COROLLA, is monopetalous, hypocrateriforme, or saucer-shaped, with a cylindric tube, divided above into eight plane spreading segments. STAMINA, two small subulate filaments, and acute erect antheræ. PISTILLUM, a roundish depressed germen, simple style, and two erect stigmas. PERICARPIUM, a roundish, didymous, bilocular berry, having two roundish seeds.

¹NYCTANTHES *Sambac*.

Sambac, or Common Arabian Jasmine.] Hath a shrubby, weak stem, branching straggling and numerous mounting upon support ten or twelve feet high; heart-shaped obtuse leaves below, and oval acute ones above, about three inches long and one broad, placed by pairs opposite; and from the upper axillas and ends of the branches small clusters of pure white, very fragrant flowers, great part of the year.

²NYCTANTHES *Undulata*.

Undulate-leaved Malabar Jasmine.] Hath a shrubby stem, branching eight or ten feet high; having taper branches; oval spear-shaped, undulate, or waved smooth leaves, by pairs opposite; and at the axillas small clusters of large snowy-white, sweet-scented flowers.

³NYCTANTHES, *Arbor Tristis*.

Arbor-tristis, or Sorrowful-tree, or Mournful Nyctanthes] Hath a shrubby, tetraginous, or square stem, branching numerous twelve or fifteen feet high; oval, acute-pointed, opposite leaves, and at the axillas clusters of white, very fragrant flowers, opening at night, and withering in the morning.

From the circumstance of the flowers of this tree blowing on nights, and fading at the approach of morning, assuming a withered mournful appearance in the day-time, it obtained the name *Arbor tristis, or Sorrowful-tree*.

⁴NYCTANTHES *Hirsuta*.

Hairy Sorrowful-tree.] Hath a shrubby stem, branching twelve or fifteen feet high; oval, smooth, shining-green leaves, placed irregularly, having hairy foot-stalks; and at the

the axillas clusters of white flowers, on hairy pedunculi, opening on nights and fade next morning.

All these shrubs are beautiful ever-greens, and flower here in our stoves annually; the first in particular is exceedingly floriferous great part of the year, and make a fine appearance; in all the sorts the flowers are hermaphrodite, and each is monopetalous, salver-shaped, and divided above into eight spreading segments (see the *Characters*); those of all the sorts have some resemblance to the common white Jasmine, but larger and more divided, and of a higher fragrance, which is somewhat like that of orange-flowers.

The plants are all tender exotics from the hot parts of India, &c. require a hot house in this country; so must be kept always in pots of rich earth, and placed constantly in that department, except about a month or two in the heat of summer, when, if thought proper, they may be set abroad; being careful, however, to remove them into the stove again early in September.

The first sort is that which is the most commonly known in the English gardens, the others are very rare in this country.

Their Propagation, &c.

Their propagation is by layers and cuttings, also sometimes by grafting.

The layers and cuttings must be of the young shoots, and spring or the early part of summer is the proper season for performing the work, which is to be effected in the usual way: observing, that if the pots containing the layers and cuttings are plunged in the bark-bed, it will forward their rooting exceedingly; each plant is afterwards to be potted separately, and plunged also in the bark-bed in the stove.

The propagation by grafting is sometimes practised upon stocks of the common white Jasmine, in the usual method in spring: observing not to suffer any shoots to grow from the stock below the graft; training the main shoot from the graft, a foot or two high to form a stem; then encourage it to branch out to form a head.

Let the plants have a due supply of water all the year; and if they grow luxuriant, prune them as you shall see convenient; and shift them into larger pots occasionally.

NYMPHÆA, (*Nymphaea*) Water-Lily.

The plants are herbaceous, very flowery perennials of the aquatic-tribe, inhabitants of our rivers and brooks; but sometimes cul-

tivated in canals, ponds, &c. of gardens, for ornament, and have a beautiful effect: they having large knotty roots, sending up very large heart-shaped leaves on long footstalks, and float on the surface of the water; and between them very large polypetalous flowers, on very long pedunculi, and shew themselves also just above the surface of the water, and are exceedingly ornamental.

Class and order, *Polyandria Monogynia*.

Characters.] CALIX, four large, coloured, permanent leaves. COROLLA, many petals (generally about fifteen) sitting on the germen, usually in more than a single series. STAMINA, numerous, short, crooked filaments, and oblong antheræ affixed to their sides. PISTILLUM, a large oval germen, no style, but an orbicular, plane target-shaped, close-fitting, crenated, permanent stigma. PERICARPIUM, a large oval, fleshy, hardy, rude, multilocular bacca, crowned at top, and filled with many roundish seeds.

The most noted species are:

¹NYMPHÆA *Lutea*.

Yellow Nymphaea.] Hath a large, knotty, spongy, deeply-striking root; very large, heart-shaped, flat-expanded, entire leaves; and large yellow flowers, having a pentaphyllous calix, larger than the petals.

²NYMPHÆA *Alba*.

White Nymphaea.] Hath a large, knotty, spongy, deeply-penetrating root; large, heart-shaped, flat-expanded, entire leaves; and large, white, sweet-scented flowers, having a quadrifid calix.

Both the species flower in June and July; the flowers are very large and conspicuous, beautifully shewing themselves on the surface of the water.

The plants are perennial in root, which strikes deep into the sand, gravel, or mud at the bottom of the water, from which arise their leaves and flowers annually, elevated to the top of the water, on long foot stalks, where they float, and just appear on the surface; the leaves generally coming up in April or May, and the flowers in June and July; succeeded by their large oval pericarpiums, filled with black shining seeds, ripening in the end of August, or in September; when being discharged from their cells, they sink to the bottom of the water, where they germinate in spring following, and young plants soon appear at top; so that the plants thus multiplying each year, and the roots of each year's plants abiding and multiplying by off-sets, they soon spread over a large space of water.

Their

Their Propagation.

The propagation of these plants in gardens is by seed cast into any piece of water where you intend they shall grow. To obtain the seeds, you must have recourse in autumn to the places where the plants grow naturally, and watch the ripening of the seed-vessels, gather a quantity just as they begin to open, which cast into the water; the seeds will sink, and the plants will appear at top in spring

after, and some of which will probably flower the ensuing summer, though it is generally the second year before they flower in perfection.

They being once thus raised, they will be of many years duration, and multiply greatly, so as to cover the whole surface of the water with their leaves and flowers in summer; so that only some small pieces of water should be allotted for this purpose.

O.

O CYMUM, (*Basilicum*) Basil.

The plants are mostly herbaceous, tender aromatic annuals, of branchy growth, proper for culinary and medical uses, and for adorning the pleasure garden; obtaining in stature, some half a yard, others little more than half a foot; closely garnished with oval and oblong simple leaves; and the stems and branches terminated by spikes of small monopetalous ringent flowers.

Class and Order, *Didynamia Gymnospermia*.

Characters.] CALIX, is monophyllous, bilabiated and permanent, the upper lip bifid, and the under acutely four-parted. COROLLA, is monopetalous, ringent, and inverted, with a short spreading tube, and with the rising lip broadest, cut into four obtuse parts, the other is long, narrow, and undivided. STAMINA, two long and two short declinated filaments, and half-moon-shaped antheræ. PISTILLUM, a four-parted germen, slender style, and bifid stigma. PERICARPIUM, none, four naked seeds lodged in the calix.

There are seven or eight species, but the most noted species in our gardens are the three following: each of which comprises many varieties; all of which are remarkable for their strong odoriferous scent, and are all of a tender quality, requiring to be raised and forwarded in a hot-bed.

¹O CYMUM *Basilicum*.

Basilicum, or Common Sweet Basil.] Rises with an upright, square, hairy stem, branch-

ing by pairs, from about ten inches to half a yard high; garnished with large, oval, smooth, opposite leaves; and the main stem and all the branches terminated by spikes of small whitish flowers, having ciliated calixes.

Varieties of this.] Broad-leaved *Basilicum*—narrow-leaved—fringed-leaved—fringed purple-leaved—curled-leaved—studded-leaved—large purple-leaved—dark-green-leaved—tricolor-leaved—red-flowered—purple flowered—long-spiked—short-spiked, &c.

This species and varieties have a piercing aromatic scent, some like cloves, others like citron, and some like fennel; they are good for culinary uses, in soup, &c. also for medical purposes; and the plants are employed for embellishing the pleasure-garden.

²O CYMUM *Minimum*.

Smallest Ocymum, commonly called Bush Basil.] Rises with a very short stem, branching all around from the bottom, about six or eight inches high, forming a round bushy head; small oval very intire leaves, by pairs opposite; and the branches terminated by whorls of very small whitish flowers.

Varieties.] With hoary leaves—dark-purple-leaved—variable-leaved.

This species and varieties are much cultivated about London, in pots to carry to market, for ornamenting balconies, windows, &c.

³O CYMUM *Tenuiflorum*.

Small-flowered China Basil.] Rises with an upright, taper, purplish stem, branching a foot

foot and a half high; oval-oblong, serrated leaves; and the main stem and branches terminated each by three slender spikes of exceedingly small flowers, having heart-shaped, concave, reflexed bractæa.

Varieties.] With white flowers—purple flowers.

All these three species of *Ocymum*, and their respective varieties, are of the annual-tribe, rising from seed in spring, flower in June and July, and ripen seeds in September, and totally perish at the approach of winter; so that a fresh supply must be raised from seed annually in spring. See their *Propagation*.

The flowers are small ringent hermaphrodites, collected into slender spikes of but little appearance.

All the species and varieties are accounted the strongest aromatics in nature, and, for the general part, the odour is very agreeable; though to some persons it is rather too powerful.

They are all exotics from India and other distant warm countries, and in these parts require to be raised and forwarded in hot-beds, as above observed, from March or April until towards the latter end of May or beginning of June, according to the temperature of the season; then may be fully exposed for the remainder of the summer.

With respect to their particular merit for our gardens, the common sort *Ocymum Basilicum*, and varieties, may be employed as culinary aromatics in the kitchen-garden; and some of all the three species, &c. as ornamental plants for the pleasure-ground, both in the open compartments, and some in pots, in order for adorning court-yards, and to place in room-windows for their sweet odour, particularly the Bush-Basil.

Their Propagation, &c.

The propagation of all the three species is by seed annually, in spring, in a hot-bed, and from which they are transplanted into the open ground, &c. in May or June.

March and beginning of April is the proper season for sowing them. Having a moderate hot-bed under a frame and glasses, earthed five or six inches depth of light mould; sow the seed a quarter of an inch deep; they will come up in a few days: observing to indulge them with fresh air daily, and occasional very moderate waterings; and when the plants are an inch or two high, prick some of them upon the same or another new

hot-bed, three or four inches asunder; or plant some singly in small pots, and plunge them in the hot-bed, give water as soon as planted, together with occasional shading from the sun till fresh-rooted; continuing the admission of fresh air daily, and repetitions of light refreshments of water: in May harden them by degrees to the full air; and about the middle or latter end of the month, or beginning of June, in warm moist weather remove them into the open air, finally to remain, taking them up with balls about their roots, and plant some in the borders, others in larger pots, to move where occasionally wanted; give water directly, and at times till they have taken fresh root, which they will soon effect, and arrive to their full growth in June and July, when they will flower, and ripen seeds in September.

To obtain more effectually some good seeds of those plants in this country, it is advisable to move some in their pots in August into a glass-case, or garden-frame, to be sheltered in cold weather, and from excessive wet; but admitting the free air in fine weather, and they will thus ripen seeds in tolerable plenty.

OCTANDRIA, the name of the eighth class: plants with hermaphrodite flowers, having eight stamina; and consists of four orders, according to the number of styles.

OENOTHERA, Tree-Primrose.

This genus of plants consists of hardy herbaceous biennials and perennials, and undershrubby perennials; all of the flowery tribe, for the decoration of the pleasure-garden; rising with upright firm stems, from one foot to three or four high, in different sorts; garnished with largish oval and spear-shaped leaves; and from the axillas on every side large, quadripetalous, primrose-shaped, yellow flowers, of considerable appearance; from June or July until October.

Class and order, *Octandria Monogynia*.

Characters.] **CALIX**, is monophyllous, long, tubular, divided at the brim into four acute reflexed segments, and is deciduous. **COROLLA**, heart-shaped plane petals, inserted into the divisions of the calix. **STAMINA**, eight awl-shaped, crooked filaments, terminated by oblong incumbent antheræ. **PISTILLUM**, a cylindric germen under the calix, filiforme style, and a thick, quadrifid, obtuse, reflexed stigma. **PERICARPIUM**, a cylindric, tetragonous, quadrilocular, quadrivalved capsule, containing many small angular seeds.

The most remarkable species of this genus in the English gardens are :

¹*OENOTHERA Biennis.*

Common Biennial Tree-Primrose.] Hath a long, thick, deeply-striking root; crowned with many large, oval, spear-shaped, plane, spreading leaves; upright, thick, firm, rough, hairy stems, rising three or four feet high; garnished with long, narrow, lanceolate, close-fitting leaves, irregularly; and at all the axillas, from the middle upwards, large bright-yellow flowers.

²*OENOTHERA Obovalvis.*

Obovalved, Smooth, Biennial Tree-Primrose.] Hath upright, firm, somewhat hairy stems, rising a yard high; oblong, spear-shaped, pointed, plane, smooth leaves; and at the axillas large bright yellow flowers.

³*OENOTHERA Fruticosa.*

Shrubby, Narrow-leaved, Perennial Tree-Primrose.] Hath long thick roots; upright, under-shrubby-like, red stems, two or three feet high; spear-shaped, lightly-indented leaves; and at the axillas pedunculated clusters of yellow flowers; succeeded by pedicelated, acute-angled capsules.

⁴*OENOTHERA Pumila.*

Low Perennial Tree-Primrose.] Hath fibrous roots; crowned with many oval, spear-shaped, close-fitting leaves; slender herbaceous stems, ten or twelve inches long; garnished with spear-shaped, blunt, smooth leaves, having very short foot-stalks; and at the axillas smallish bright-yellow flowers; succeeded by acute-angled capsules.

All these plants flower very profusely in June and July, coming out almost half the length of the stalks from the axillas; and as the stalk advances in stature, new flowers are produced, succeeding those below; in which order the plants continue flowering from about Midsummer until October; each flower is moderately large and conspicuous, consisting of four plane petals, which with the calix forms a very long tube below, and spreading above, generally expand most towards the evening; and are succeeded by plenty of seed in autumn for propagation.

These plants are exotics from America, but are all very hardy, prosper in any common soil and situation, and have been long in the the English gardens, especially the first three sorts, but the *Oenothera Biennis* is the most commonly known.

The first and second species are biennial, and the third and fourth are perennial in root.

They are proper to be employed as plants of ornament for embellishing the pleasure-garden; they may be placed any where, and will effect a very agreeable variety three or four months with their plentiful blow of flowers.

The biennial kinds must be raised annually from seed, for they totally perish soon after they have flowered.

But the perennials, once raised, continue for years by the root.

Their Propagation.

The propagation of all the sorts is by seed, and the perennials also by parting the roots.

By Seed.—By this method both biennials and perennials may be raised plentifully in any bed or border of common earth. Sow the seed either in autumn or early in spring; the autumnal sowings will rise strong betimes in the spring. In May or June, when the plants are two or three inches high, thin them where too close; at the same time plant out a quantity in nursery-rows six inches asunder; give occasional weeding, and plenty of water in dry weather; and in autumn they may be taken up with balls of earth about their roots, and planted where they are finally to remain.

By Parting the Roots.—The perennials being abiding, and multiplying by off-sets of the roots; they may be propagated by dividing the roots into slips, in autumn or spring; each slip becomes a proper plant, producing flowers the following summer.

OFF-SETS, a sort of suckers, or small young plants, issuing from the sides of the main roots of many sorts of perennials, both bulbous, tuberous, and fibrous-rooted kinds, by which vast numbers of plants are propagated, as each Off-set becomes a proper plant, alike in every respect to the parent.

But Off-sets are applicable most commonly to bulbous and tuberous-rooted perennials, such as tulips, anemonies, &c. the Off-sets of which are small bulbs and tubers; and as most of the bulbous and tuberous-rooted tribe send forth plenty of Off-set roots from the sides of the main ones annually, it is a certain, easy, and expeditious method of propagating all these kinds of plants, and each Off-set commences a new plant, producing stalks, leaves, flowers, fruit, &c. exactly like those of the parent plant; so that having some roots of any particular approved species and varieties, you may increase them annually by the Off-sets, and which, after having one or

two years growth, will flower, produce seed, and furnish a supply of Off-sets in their turn: all still continuing the same as the mother-plant in every mode of growth.

Off-sets, in the article of propagation, have this particular advantage over seedlings, that those of the flowery kind will often flower in one year: whereas seedling plants of the bulbous kinds are frequently four, five, and sometimes six or seven years before they flower in perfection; so that seedlings are principally to gain new varieties; and the roots of which furnishing Off-sets the varieties are increased.

As to the mode of separating Off-sets, it may be done in some sorts every year, in others once in two or three years, according to the sorts, and the increase of Off-sets the main roots shall afford; which is always explained in the culture of the respective sorts, under their proper genera.

The proper season for separating Off-sets is, in the bulbous and many tuberous-rooted plants, chiefly summer and autumn, when they have done flowering, and the leaves decay, for at that period the roots of these sorts having had their full growth for that season, they assume an inactive state of growth, not drawing any nourishment from the earth: they continuing at rest, however, but a few weeks, attention must be had to take the opportunity of that interval, before they put out new fibres; which is the only proper period for moving all the bulbous kinds in particular, both to separate the Off-sets, and for transplanting the main roots, as for taking them up for keeping for a month or two, or longer. See BULBUS. Observing therefore the proper time, and having taken up the roots in dry weather if possible, let all the Off-sets be separated singly from the main bulb, &c. and plant the Off-sets in nursery-beds, in rows six inches asunder, drilling them in with a hoe, two or three inches deep; and here let them remain a year or two, according to their size, to get strength; then transplant them, at the proper season, where they are to continue, managing them as other bulbous and tuberous-rooted plants. See BULBUS, RADIX, &c.

But with respect to Off sets of fibrous-rooted perennials, you may either slip off the principal ones from the sides of the main root, as they stand in the ground, or the root may be wholly taken up, and parted into as many slips as there are Off-sets furnished with fibres. The proper season for this is autumn,

when their stalks decay, or early in spring before new ones begin to shoot forth; though some hardy sorts may be slipped any time in open weather from September or October until February, planting them by dibble, the smaller Off-sets or slips in nursery-beds, in rows six or eight inches asunder, to have a year's growth; and the larger ones may be planted at once where they are to remain, and they will flower the ensuing season.

Several sorts of shrubby perennials encrease by also Off-sets at bottom; and the proper season for taking them off is autumn and spring, or in hardy kinds it might be done any time in open weather, from October until March; planting them in nursery-rows for a year or two, or till of proper size for the purposes for which they are designed.

Off-sets of succulent plants should generally be slipped off in summer; and previous to planting those of the tender kinds, should be laid on a dry shelf for some days, till the moisture at bottom is dried up; then planted in pots of dry soil, and managed according to their different temperatures. See SUCCULENTÆ. No Off-sets are ever to be expected from annual plants.

OLEA, Olive-tree.

This genus consists of two ever-green exotic-trees for the green-house collection; generally assuming a shrubby-like growth, by rising frequently with several stems from the bottom, branching laterally all the way; one sort obtaining in stature twenty or thirty feet high, the other but six or seven feet; garnished with spear-shaped and oval stiff leaves, and clusters of funnel-shaped flowers from the axillas; succeeded by that well-known oval fruit called Olives, in great estimation abroad for making oil, and for pickling, &c. but in this country the plants are retained principally for variety, as the fruit rarely attains due perfection.

Class and order, *Diandria Monogynia*.

Characters.] CALIX is small, monophyllous, tubulous, quadridented, and deciduous. COROLLA, is monopetalous, infundibuliforme, with the top quadripartite and spreading. STAMINA, two short filaments, and erect antheræ. PISTILLUM, a roundish germen, short style, and thick bifid stigma. PERICARPIUM, a suboval, smooth, unilocular, drupaceous fruit, including an oblong-oval nut.

There are but two species, one of which, however, comprises many varieties with respect to the fruit.

The species are ;

¹*OLEA Europæa.*

European Common Olive-tree.] Rises with upright solid stems, branching numerously on every side, twenty or thirty feet high ; spear-shaped, stiff, opposite leaves, two or three inches long, and half an inch or more broad ; and at the axillas small clusters of white flowers, succeeded by oval fruit.

This species is the principal sort cultivated for its fruit ; the varieties of which are numerous, varying in size, colour, and quality.

It is a native of the southern warm parts of Europe, and is cultivated in great quantities in the south of France, Italy, and Portugal, for the fruit to make the Olive-oil, which is in so great repute, and is transported to all parts, to the great advantage of those countries where the trees grow in the open ground : the green fruit is also in much esteem for pickling, of which we may see plenty in the shops.

²*OLEA Capensis.*

Cape Box-leaved Olive.] Rises with shrubby stems, branching numerously from the bottom, six or seven feet high ; small, oval, thick, stiff, shining leaves ; and at the axillas small clusters of whitish flowers ; succeeded by small fruit of inferior value.

These plants in this country must be kept principally in pots for moving to shelter of a green-house in winter ; for they are too tender to prosper well in the open ground here ; though sometimes they are planted against a warm south wall, and sheltered occasionally from frost in winter, by mulching the roots, and matting their tops ; whereby they may be preserved, and will sometimes produce fruit for pickling ; a very severe winter, however, often kills or greatly injures their young branches ; therefore let the principal part be potted in rich earth, and placed among the green-house shrubs, and managed as directed in the article GREEN-HOUSE PLANTS.

These trees are often sent over from Italy to the Italian warehouses in London, along with orange-trees, &c. where pretty large plants may be purchased reasonably, which should be managed as directed for orange-trees that are imported from the same country. See CITRUS.

Their propagation here is commonly by layers.

The laying is performed on the young branches in spring ; give plenty of water all

summer, and they will sometimes be rooted fit for potting-off by autumn ; but sometimes they require two summers to be rooted effectually : when, however, they are properly rooted, take them off early in autumn, and pot them separately, give water, and place them in the shade till they have taken fresh root ; and in October remove them into the green-house, &c.

Those you intend to plant in the open-ground, as before suggested, should be kept in pots, in order to have occasional shelter of a garden-frame two or three years, till they have acquired some size, and are hardened to the full air ; then transplant them into a warm border against a wall : mulch their roots in winter, and mat their tops in frosty weather.

ONONIS, Rest-Harrow.

It consists of hardy herbaceous perennials and annuals, and some shrubby plants ; several of the former are troublesome weeds in the fields, and some of the latter are proper for ornamenting the pleasure-ground ; most of the sorts grow erect from about one foot to two or three high ; garnished some with simple, others with trifoliate leaves ; and papilionaceous flowers.

Class and order, *Diadelphia Decandria.*

Characters.] CALIX, is divided into five narrow arched segments, the lower ones bending under the carina. COROLLA, is papilionaceous, the standard heart shaped, and depressed on the sides, short oval wings, and a pointed carina. STAMINA, ten diadelphous filaments, and simple antheræ. PISTILLUM, an oblong hairy germen, simple style, and obtuse stigma. PERICARPIUM, a turgid, unilocular, bivalved pod, having kidney-shaped seeds.

There are many species, several of which are common weeds, often very troublesome in the fields, their roots spreading widely around, and are so tough and strong, as sometimes to retard the progress of the husbandman's harrow ; whence originated the English name, Rest-harrow.

The most material species common to the gardens, are the following shrubby kinds.

¹*ONONIS Fruticosa.*

Shrubby Purple Rest-harrow.] Rises with slender, shrubby, durable stems, branching numerously two or three feet high ; spear-shaped, serrated, ternate leaves ; and all the branches terminated by panicles of large red flowers, three on each pedunculi.

²ONONIS

²ONONIS *Tridentata*.

Tridented Shrubby Rest-harrow.] Rises with shrubby, slender stems, branching half a yard high; narrow, fleshy, ternate leaves, tridented at the top; and the branches terminated by panicles of purple flowers, two on each pedunculi.

Both these shrubs flower very ornamentally in May or June, the flowers are papilionaceous or butterfly-shaped, large and conspicuous, and are succeeded by ripe seeds in autumn.

The first sort is very hardy, and proper for the shrubbery.

The second requires shelter from frost, so should generally be kept in pots, in order for moving to a green-house or garden-frame in winter.

Their propagation is by seed, sowed in April in a warm border, half an inch deep; or if those of the second sort are sowed in pots and plunged in a slender hot-bed, they will more certainly succeed; the plants will come up in May; give plenty of water all summer, and indulge the second sort with shelter in winter; in spring plant out both sorts; the first in nursery-rows a foot asunder, to remain a year or two, when they will be fit for the shrubbery; and the second plant in pots for moving to shelter in autumn.

OPHRYS, Twyblade, Bee-flower, &c.

This genus is composed of herbaceous, bulbo-fibrous-rooted perennials, mostly inhabitants of our woods, pastures, meadows, and some hilly grounds, but frequently employed in the pleasure-garden for the singularity of their flowers; most of them are low plants, with erect annual stalks, from three or four inches to a foot high; some naked and some foliated, and terminated by spikes of small pentapetalous nectariferous flowers, frequently of singular shapes, resembling in some sorts the figures of men, and various sorts of insects, as flies, bees, &c.

Class and order, *Gynandria Diandria*.

Characters.] CALIX, a vague spatha, protruding a simple spadix of flowers, without any perianthium. COROLLA, five oblong, equal-ascending petals, and a dependent long nectarium, keel-shaped behind. STAMINA, two very short gynandrous filaments, and erect antheræ. PISTILLUM, an oblong contorted germen below the flower, a style adhering to the inner border of the nectarium, and obsolete stigma. PERICARPIUM, a tri-

gonal, unilocular, trivalvular capsule, filled with numerous seeds like dust.

The English name *Twyblade*, is from some of the species being remarkable for having only two leaves.

There are many species, but the most noted are the following, which are admitted into some pleasure-gardens for variety.

¹OPHRYS *Ovata*.

Oval-leaved Ophrys, or Common Twyblade.] Hath a bulbous, fibrated root; crowned by two oval, broad, obtuse, veined, opposite leaves; an erect, succulent, green stalk, six or eight inches high, naked above, and terminated by a loose spike of greenish flowers, having the lip of the nectarium bifid.

The flowers of this species resemble the figure of gnats.

²OPHRYS *Spiralis*.

Spiral Orchis, or Triple Ladies Traces.] Hath bulbous, oblong, aggregated roots; crowned by a cluster of oval, pointed, ribbed leaves; erect simple stalks, half a foot high; terminated by long spikes of white, odoriferous flowers, hanging to one side, having the lip of the nectarium entire, and crenated.

³OPHRYS *Nidus-avis*.

Nidus-avis, or Birds-nest.] Hath a bulbous, fibrated, clustered root; upright, thick, succulent stalks, a foot high, sheathed by the leaves, and terminated by loose spikes of pale-brown flowers; having the lip of the nectarium bifid.

⁴OPHRYS *Anthropophora*.

Man-shaped Ophrys, or Man Orchis.] Hath a roundish bulbous root; crowned with three or four oblong leaves; upright thick stalks, rising a foot and a half high; adorned with narrow leaves, and terminate by loose spikes of greenish flowers, representing the figure of a naked man; the lip of the nectarium linear tripartite, with the middle segment longest and bifid.

Variety.] With brownish flowers tinged with green.

⁵OPHRYS *Insectifera*.

Insectiferous Ophrys, or Insect Orchis.] Hath two roundish bulbous roots; crowned with oblong leaves; erect leafy stalks, from six to ten or twelve inches high, terminated by spikes of insect-shaped greenish flowers, having the lip of the nectarium almost five-lobed.

This wonderful species exhibit flowers in different varieties, that represent singular figures

gures of flies, bees, and other insects; and are of different colours in the varieties.

Varieties are.] Fly-shaped *Ophrys*—great fly *Ophrys*—large green fly *Ophrys*—blue fly *Ophrys*—yellow fly *Ophrys*—bee *Ophrys*—large bee *Ophrys*—black bee *Ophrys*—green winged bee *Ophrys*—beetle *Ophrys*—spider *Ophrys*.

⁶*OPHRYS Monorchis.*

Monorchis, or Musky Ophrys.] Hath a roundish bulbous root; crowned with three or four oblong leaves; an erect naked stalk, six inches high; terminated by a loose spike of yellowish, musky-scented flowers.

All these six species of *Ophrys* flower in summer, at different times in different sorts, from May until July; and in most of the sorts exhibit a singularly curious appearance.

The plants are all perennial in root, which are of the bulbous fleshy kind, from which the flower-stalks rise annually in spring, and decay in autumn; at which period is the proper time for removing the roots from one place to another.

They all grow wild in England, &c. are residents of woods, bogs, marshy grounds, sterile pastures, chalky soils, and the like places, where they flourish and display their singular flowers in great abundance, from which places they are introduced into gardens for variety; and having procured some plants at the proper season, and planted them in soils and situations somewhat similar to that where they naturally grow, the roots will abide for several years, and flower annually.

They may be easily obtained from the places where they naturally grow, and are kept at most of the public nurseries for sale.

The proper season for removing them is in summer when the stalks decay; therefore repairing either to the places of their growth, when in full bloom, or to the nurseries, mark a quantity of the best plants with sticks; and when the stalks and leaves assume a decayed state, proceed to dig up the roots, and bring them into the garden and plant them directly.

It is proper to suit the situation and soil of the different sorts as near as possible; those of the woods place in shady moist borders, or in shrubbery quarters among trees; those of boggy or marshy ground, plant in the moistest parts of the garden; and those found on dry sterile plains or commons, should have a dry open exposure.

Having planted them, let them remain constantly undisturbed, unless particularly

wanted to be removed from one place to another, for the less they are disturbed the better they will flower.

As to their propagation, it may be tried by seed in a shady border, as soon as it is ripe; likewise by off sets from the root, though they multiply sparingly in gardens; however roots of some standing may be examined at the proper season, and any off-sets separated and planted directly in the proper places.

ORCHARD, a garden-department, consigned intirely to the growth of standard fruit-trees, for furnishing a large supply of the most useful kinds of fruit.

In the orchard you may have as standards all sorts of apple-trees, most sorts of pears and plums, and all sorts of cherries; which four species are the capital Orchard-fruits; each of which comprise numerous valuable varieties; but to have a complete Orchard, may also have quinces, medlars, mulberries, service-trees, filberts, Spanish nuts, berberies; likewise walnuts and chesnuts; which two latter are particularly applicable for the boundaries of Orchards, to screen the other trees from the insults of impetuous winds and cold blasts: all of which trees being arranged in rows from twenty to thirty feet distance, as hereafter directed.

But sometimes Orchards consist intirely of apple-trees, particularly in the cyder-making countries, where they are cultivated in very great quantities in large fields, and in hedge-rows, for the fruit to make cyder for public supply.

And sometimes whole Orchards of very considerable extent are intirely of cherry-trees; but in this case, it is when the fruit is designed for sale in some great city, as London, &c. for the supply of which city, great numbers of large Cherry-Orchards are in some of the adjacent counties, but more particularly in Kent, which is famous for very extensive Cherry-Orchards; many of which are entirely of that sort called Kentish cherry, as being generally a great bearer; others are stored with all the principal sorts of cultivated cherries, from the earliest to the latest kinds. See *PRUNUS Cerasus*.

A general Orchard, however, composed of all the before mentioned fruit-trees, should consist of a double portion of apple-trees or more, because they are considerably the most useful fruit, and may be continued for use the year round.

The

The utility of a general Orchard, both for private use and for profit, stored with the various sorts of fruit-trees, must be very great, as well as afford infinite pleasure from the delightful appearance it makes from early spring till late in autumn: in spring the various trees in blossom are highly ornamental; in summer, the pleasure is heightened by observing the various fruits advancing to perfection; and as the season advances, the mature growth of the various sorts arriving to perfection in regular succession from May or June until the end of October, must afford exceeding delight, as well as great profit.

Of the proper Extent, Situation, and Soil, for this Department.

As to the proper extent of ground for an Orchard, this must be proportioned, in some measure to the extent of land you have to work on, and the quantity of fruit required either for private use, or for public supply: so that an orchard may be from half an acre to twenty or more extent.

With respect to the situation and aspect for an Orchard, we may observe very thriving Orchards both in low and high situations, and on declivities and plains, in various aspects or exposures, provided the natural soil is good: I should, however, avoid very low damp situations as much as the nature of the place will admit; for in very wet soils no fruit-trees will prosper, nor the fruit be fine; but a moderately low situation, free from copious wet, may be more eligible than an elevated ground, as being less exposed to tempestuous winds; though a situation having a small declivity is very desirable, especially if its aspect incline towards the east, south-east, or southerly, which are rather more eligible than a westerly aspect; but a north aspect is the worst of all for an Orchard, unless particularly compensated by the peculiar temperament or good quality of the soil: I would, however, remark, for the advantage of those that are not accommodated with choice of situation and aspect, that they need not be under any great anxiety, provided as above said, if the soil is but suitable; only observing, if possible, to abandon very low damp situations, for the reason before given.

And as for soil, any common field or pasture that produces good crops of corn, grass, or kitchen-garden vegetables, is suitable for an Orchard;

if it should prove of a loamy nature, it will be a particular advantage: any soil, however, of a good quality, not too light and dry, or too heavy, stubborn, or wet, but of a medium nature of a soft pliant temperature, not less than one spade deep of good staple, will be proper for this purpose.

Where, however, the soil is naturally defective, the defects must be rectified as well as possible, by the application of proper manures, and composts prepared as directed under those articles, and applied either to the whole ground, if but of moderate extent, or to the places where each tree is to stand, for a space of eight or ten feet circumference, working it up with the natural soil of the place.

This, however, in extensive Orchards, would be a very chargeable operation; therefore those who are at liberty to chuse, should have particular regard to the fixing upon a proper spot, where but little or no foreign aid is requisite.

Preparation of the Ground.

The preparation of the ground for the reception of the trees, is by trenching, or if for very considerable Orchards, by deep ploughing; but trench-digging, one or two spades, as the soil will admit, is the most eligible, either wholly, or only for the present, in the places where the lines of trees are to stand, a space of six or eight feet wide, all the way in each row, especially if it be grass-ground, and intended to be kept in sward; or if any under-crops are designed to be raised, the ground may be wholly trenched at first; but as to this you may suit your convenience, observing in either case to trench the ground in the usual way to the depth of the natural soil; and if in grass, turn the sward clean to the bottom of each trench, which, when rotted, will prove an excellent manure.

In planting Orchards, however, on grass-ground, some only dig pits for each tree, capacious enough for the reception of the roots, loosening the bottom well, without the labour of digging any other part of the ground: where the ground, however, is trenched either wholly, or some considerable width along the place of each row of trees, it will consequently prove of greater advantage in promoting their free growth.

The ground must be fenced securely against cattle, &c. either with a good ditch and hedge,

hedge, or with a paling-fence, as may be most convenient. See HEDGES.

Method of planting the Trees.

The best season for planting all the sorts of fruit-trees is autumn, soon after the fall of the leaf, from about the latter end of October until December; or indeed it might be performed any time in open weather from October until March.

All the sorts of fruit-trees proper for this department, if not furnished with them in your own nursery, may be had very reasonable at all the public nursery-grounds; observing to chuse them principally full standards, with streight clean stems, six feet high, especially the apples, pears, plums, cherries, and other tree kinds, each with a branchy well-formed head, of from two or three to four or five years growth; and let several varieties of each particular species be chosen, that ripen their fruit at different times, from the earliest to the latest, according to the nature of the different sorts, that there may be a sufficient supply of every sort regularly during their proper season; and of apples and pears in particular, chuse a much greater quantity of the autumnal and late-ripening kinds, than the early sorts; but most of all of apples: for the summer-ripening fruit is but of short duration, only proper for temporary service; but the later-ripening kinds keep sound some considerable time for autumnal use; and the latest sorts that ripen in October, continue in perfection for various uses all winter, and several sorts until the season of apples come again. See the list of the different sorts of fruit in this work, under their respective genera.

Having made choice of the proper sorts, and marked them, let them be taken up with the utmost care, so as to preserve all their roots as entire as possible; and when taken up, prune off any broken or bruised parts of the roots, and just tip the ends of the principal roots in general with the knife, on the under side, with a kind of slope outward.

If the trees have been already headed, or so trained as to have branched out into regular shoots to form each a proper head, they must be planted with the said heads entire, only retrenching or shortening any irregular or ill-placed shoot that take an aukward direction, or grow across its neighbours, or such that may run considerably longer than all the rest,

&c. as observed under the respective articles in training them for standards, also in the article STANDARD-TREES.

The arrangement of the trees in the Orchard must be in rows, each kind separate, at distances according to the nature of growth of the different sorts; but for the larger growing kinds, such as apples, pears, plums, cherries, &c. they should stand from twenty-five to thirty or forty feet every way asunder, though twenty-five or thirty feet at most is a reasonable distance for all these kinds.

Each species and its varieties should generally be in rows by themselves, the better to suit their respective modes of growth: tho' for variety may have some rows of apples and pears arranged alternately; as also plums and cherries; and towards the boundaries may have ranges of lesser growth, as quinces, medlars, filberts, &c. and the outer row of all may be walnut-trees, and some chesnuts, set pretty close to defend the other trees from violent winds.

According to the above distances proceed to stake out the ground, for making the holes for the reception of the trees; which if made to range every way, will have a very agreeable effect, and admit the currency of air, and the sun's influence more effectually.

But in planting very extensive Orchards, some divide the ground into large squares or quarters of different dimensions, with intervals of fifty feet wide between: serving both as walks, and for admitting a greater currency of air: in different quarters planting different sorts of fruit, as apples in one, pears in another, and plums and cherries in others, &c. and thus it may be repeated to as many quarters, for each species and its varieties, as may be convenient.

As to the mode of planting the trees, it is the same as directed under their several articles, and the article PLANTING. A wide hole must be dug for each tree, capacious enough to receive all the roots freely every way without touching the sides. When the holes are all ready, proceed to planting, one tree to each hole, a person holding the stem erect, whilst another trims in the earth, previously breaking it small; and cast it in equally about all the roots, frequently shaking the tree to cause the mould to settle in close about all the smaller roots and fibres, and so as to raise the tree gradually up, that the crown of the roots may be but two or three inches below

low the general surface; and when the hole is filled up, tread it gently, first round the outside, then near the stem of the tree; forming the surface a little hollow; and then if on the top of all is laid some inverted turf to the width of the holes, forming it with a sort of circular bank, three or four inches high, it will support the tree, and guard the roots from drying winds, and the summer's drought: observing that each tree stands perfectly upright, and that they range exactly in their proper rows.

If the orchard is much exposed to the winds, it may be proper to stake the new-planted trees to support them in their proper position, and secure them from being rocked to and fro by the wind, which would greatly retard their rooting afresh; placing one or two strong tall stakes to each tree; but the most effectual method is to have three stakes to each, placed in a triangle, meeting at top near the head of the tree, wrapping a hay-band round that part of the stem, to prevent its being barked by the stakes or tying; then tie the stakes at top close to the tree with some proper bandage, bringing it close about the stem and stakes together, over the hay-wrapping, in a proper manner to secure the tree firmly in an erect posture.

The ground of the Orchard, between the rows of trees, is very commonly laid down in grass, as being the most convenient for admitting of coming readily at the trees at all times to gather the fruit: but if thought proper, it may be employed for some years either wholly, or in part, for the produce of kitchen vegetables, or for the growth of corn, turneps, potatoes, &c. being careful in digging or ploughing the ground for the reception of these crops, not to go too near to disturb the roots of the trees; likewise not to have any strong-growing plants within three feet of each side of the rows of trees: however, after the trees are advanced in growth, and begin to bear any thing considerably, it may be more eligible to lay the ground down intirely in grass, as it will be then more in character of an orchard, and be more convenient for gathering the fruit, and doing any necessary work to the trees; but in any of these ways, every one may suit their inclination or convenience.

If, however, it is laid down in grass, no cattle should be turned in to graze at large, unless the stems of each tree is previously well secured with posts and railing, and watted with thorn-bushes, especially in young

Orchards, otherwise they will bark the trees, to their very great injury, nor should large cattle be turned in to Orchards, where the branches of the trees are yet low and within their reach.

General Culture.

With regard to the general culture of Orchard fruit-trees, observe for one thing, that as being standards, their heads should generally be permitted to branch out nearly in their own natural manner, with the branches at full length, without shortening, only on particular occasions, and they will gradually form themselves into large branchy heads, and all the branches soon assume a bearing state; very little pruning of any sort being required to standard fruit-trees, except in particular cases, as above hinted, of superfluous or very irregular growths; as for example, all suckers arising from the root, must constantly be taken off close; likewise divest the stems of all side-branches coming out below the head; and all luxuriant shoots arising in the heart or middle of the tree, or in any part where they appear too much crowded, should be pruned off close: if any particular branch of the head should become of very long straggling growth, extending considerably beyond all the rest, it may be shortened as you shall see proper, down to some young shoot, or lower branch it supports, so as to preserve a little regularity; likewise any branch that takes an irregular direction across the others, or any other awkward growth, such may either be shortened down to any lower branch it supports that is of a regular growth, or intirely retrenched as it may seem proper to keep up some uniformity in the head; and if the head in general becomes at any time over-crowded with branches, thin out the worst and most irregular growers of the superfluity: all dead wood and cankered parts should also be cut off to the live wood.

But remarking, that, except in the above cases, the branches in general of standard fruit-trees, in every stage of growth, should be suffered to shoot forth, both in length and branch, laterally in their own way; for as most of the sorts first form their fruit-buds, or spurs, near the extremity of the branches or shoots, if pruning their ends was practised, it would not only be cutting off the parts where the fruit would have been first produced, but would force out a number of lateral useless shoots, and crowd the tree with superfluous or unnecessary wood, and greatly retard the branches

branches from forming the above fruit-spurs or buds for bearing; and unless these are formed in plenty, none of the principal tree-kinds can ever produce any tolerable crops of fruit; but the trees being suffered to take their natural growth, according to the above rules, all the branches and shoots will gradually form fruit-spurs towards their extreme parts, at almost every eye or bud.

By the above hints it is obvious that standard fruit trees require but very little culture in respect to pruning; and the less they are pruned, except in the before mentioned cases, the better they will bear.

Besides, to attempt at any regular pruning of Orchard or other standard fruit-trees, would prove a very tedious as well as unnecessary work.

When necessary, however, to prune any of these trees occasionally in the above cases, observe that the proper season for that work is any time from the fall of the leaf until March. Likewise observe in performing that operation, that such branches as require retrenching should be cut off quite close either to their origin, if necessary, or close to any more convenient branch it may support, not leaving any stump, and make the cut as even and smooth as possible.

Orchard-trees are sometimes greatly infested with moss growing all over their branches, but more particularly those trees which are situated in very damp soils; also often in old Orchards where the trees stand so close as to crowd one another so considerably as to exclude the free air: in which case of mossiness, the trees commonly assume a stunted unkindly growth, producing but indifferent crops, and the fruit often small and ill-flavoured. The only remedy for this disaster, is, to thin out some of the branches where thickest, to admit the sun and air more freely, and scrape the moss off from the remainder, with an instrument directed below; but where the trees thus infested stand very close to one another, some of them should be cut down to admit a larger portion of air, and the sun's heat and light; and for the same reason thin the branches of the remaining trees; then clear the branches in general from the grossest of the moss; for which purpose you should be provided with some iron scrapers hollowed on the edge, and of three different sizes to suit the different branches, having the edges a little blunted; and with these tools scrape off the moss from all the principal branches at least, and of as many of the smaller ones as

your time will permit, for it is tedious work where there are many trees: after this, if the ground of the Orchard, either wholly or but ten or twelve feet width along each row of trees, is dug or deeply ploughed, it will give new vigour to the roots, and which together with the thinning of the trees to admit the sun and air freely, and the principal branches being divested of the moss, you will find them shoot at top with fresh vigour, and the quantity, size, and quality of the fruit be greatly augmented in a year or two.

For farther remarks respecting the particular culture of each different species, and its varieties, cultivated as Orchard-trees, see the several articles under their respective genera.

And with respect to the times of ripening of the different fruits, time and method of gathering the various kinds, and of preserving those of the keeping sorts, it is properly exhibited in all the different articles under their proper heads.

ORCHIS, (*Orchis*) Fool-stones.

The plants are hardy, herbaceous, bulbous-rooted, flowery perennials, mostly natives of our meadows, pastures, woods, and uncultivated places, and which, like the species of *Ophrys*, having great singularity in their flowers, are admitted into pleasure-gardens for variety; most of them have roots composed of two testiculated bulbs, sending up annually one or more flower-stalks, from about five or six inches to half a yard high; terminated by spikes of pentapetalous nectariferous flowers of various odd figures in different species, resembling sometimes a naked man, sometimes a butterfly, gnat, and other strange shapes.

Class and order, *Gynandria Diandria*.

Characters.] CALIX, a vague spatha, protruding a simple spadix of flowers, without perianthiums. COROLLA, five petals, three of them exterior and two interior, rise upward and meet; and a monophyllous nectarium between the divisions of the petals, having a short upper lip; the under large, broad, and spreading; with the tube nutant and horn-shaped. STAMINA, two short gynandrous filaments, and oval erect antheræ. PISTILLUM, an oblong contorted germen below the flower, very short style, and a compressed obtuse stigma. PERICARPIUM, an oblong, three-keeled, trivalvate, unilocular capsule, filled with numerous seeds.

The roots of most of the species of this genus being composed of two oblong fleshy bulbs joined together, bearing an obvious resemblance to the scrotum, or testiculi of animals,

mals, it derives both its generic name, and the English appellation, Fool-stones, &c. Most of the species are celebrated provocatives, which restorative quality is chiefly possessed by the roots; of which also by a late discovery may be prepared a powder for making salep, nearly resembling that from Turkey, the alimentary virtues of which are well known.

There are numerous species, but the most remarkable are the following:

¹*ORCHIS Masculula.*

Male Fool-stones.] Hath a root composed of two bulbs; crowned with oblong, broad, spotted leaves; upright flower-stalks, a foot high; garnished with one or two narrow amplexicaule leaves; and terminated by a long spike of reddish-purple flowers, having the petals reflexed backward; a quadrilobed crenated lip to the nectarium, and an obtuse horn.

The flowers of this species possess a very agreeable odour.

It grows wild in meadows and pastures.

²*ORCHIS Morio.*

Morio, or Female Orchis.] Hath a double bulbous-root; crowned with oblong, ribbed, spreading leaves; erect flower-stalks, eight or ten inches high; garnished with a few amplexicaule leaves; and terminated by a short loose spike of flowers, having connivent petals; a quadrifid crenated lip to the nectarium, and an obtuse horn.

Varieties.] Purple-flowered—red-flowered—violet-coloured—flesh-coloured—and white-flowered.

It grows naturally in woods and rough places.

³*ORCHIS Militaris.*

Military, or Man Orchis.] Hath a double bulbous root; crowned with oblong amplexicaule leaves; erect flower-stalks, eight or ten inches high; terminated by a loose spike of ash-coloured and reddish flowers, having confluent petals; a quinquefid, rough, spotted lip to the nectarium, and an obtuse horn.

The structure of the flowers exhibit the figure of a naked man; and are often of different colours in the same flower, as ash-colour, red, brown, and dark-striped.

It grows in chalky soils, and pasture grounds.

⁴*ORCHIS Bifolia.*

Bifoliated, or Two-leaved Common Butterfly-Orchis.] Hath a double bulbous root; crowned with usually two, or from two to four oblong leaves; upright flower-stalks, eight or

ten inches high, garnished with a few small amplexicaule leaves; and terminated by a loose spike of butterfly-shaped white flowers, with spreading petals; a spear-shaped entire lip to the nectarium, and a very long horn.

This is a resident of rough pastures, and bushy places.

⁵*ORCHIS Latifolia.*

Broad-leaved Handed Orchis.] Hath a double, bulbous, sub-palmated or almost hand-shaped, straight root; upright thick flower-stalks, ten or twelve inches high; garnished the whole length with long, broad, amplexicaule leaves; and terminated by a short close spike of red purple-spotted flowers, having a conical-shaped horn to the nectari; a trilobate lip reflexed on the sides, and with bractæa longer than the flowers.

It grows naturally in meadows and pastures.

⁶*ORCHIS Maculata.*

Maculated, or Spotted, Handed Orchis.] Hath a double, bulbous, palmated root, with the divisions spreading wide asunder; upright, thick, spotted flower-stalks, a foot or more high, fully garnished with long, narrow, dark-spotted amplexicaule leaves; and terminated by a close spike of flowers, having the hinder part of the petals spreading; a plane, trifid, spotted lip to the nectari, and the horn shorter than the germen.

Varieties.] Purple-flowered—deep purple—rose-coloured—and white flowered.

They are residents of moist meadows and pastures.

⁷*ORCHIS Abortiva.*

Abortive Orchis, or Purple Bird's-Nest.] Hath bulbous roots clustered together; upright, thick, purple stalks, a foot and a half high; sheathed with narrow purplish leaves; and terminated by a loose thyrses of purple flowers, having the lip of the nectarium oval and entire.

It grows wild in meadows and shady places.

⁸*ORCHIS Conopsea.*

Gnat Orchis.] Hath a bulbous palmated root; crowned with long narrow spotless leaves; upright stalks, a foot high; sheathed with short narrow leaves; and terminated by a long spike of red flowers, having two of the petals spreading; a trifid-lipped nectarium, and a bristly horn longer than the germen.

It is an inhabitant of meadows and upland pastures.

All these *Orchises* are very hardy perennials, with bulbous fleshy roots; durable by the root, but annual in leaves and flower-stalks; most

most of them are natives of England, growing wild, some sorts in meadows, woods, and pastures; others in dry sterile uncultivated soils; but for the singularity and beauty of the flowers, are introduced into many curious gardens to encrease the variety in the herbaceous collection, and may be procured from the places where they grow spontaneously, which is in many parts of the kingdom: several of the sorts are also retained in the public nurseries for sale.

They flower in May, June, and July, but principally in June; their mode of flowering is universally in spikes, many flowers in each spike; and each flower is composed of five petals in two series, and a nectarium. See the *Characters*.

A few of these singular plants may be disposed in different parts of the pleasure-garden, in any of the compartments where they may be the most conspicuous; they, however, are the most prosperous in a situation and soil somewhat similar to that where they naturally grow.

The season for removing them is in summer, after they have done flowering, when their leaves and stalks decay: mark this particularly, and it is advisable to plant them again as soon as possible after removal; planting them three inches deep; and let them remain undisturbed several years, for the less they are removed the stronger they will flower.

We formerly observed, that the roots of these plants were possessed of very nutritious virtues, particularly for making salep. By a late discovery communicated to the Royal Society, it appears that the root of the *Orchis Masculula*, with most of the other *Orchis*-roots of our own country, may be prepared a powder to resemble the *Salep* that comes from Turkey; the alimentary virtues of which, as before observed, are well known, as well as its exorbitant high price, which confines it in a great degree only to persons of affluent circumstances; but as many of the species of *Orchis* are indigenous plants of Britain, growing spontaneously in most parts of the kingdom, and as they flourish in almost any dry barren soil, by a little culture, all ranks of people might in a short time be accommodated with this nutritious vegetable for making salep powder; and for encouraging its propagation, the Society of Arts and Sciences in London have lately offered premiums.

Their propagation may be tried both by seed and by off-sets of the roots.

By Seed.—This must be very carefully collected in the places where the plants grow naturally; and sow it directly in the garden, in a border of light earth, and rake it in with a light and even hand; and if it grows freely, the plants may either be thinned and remain where sowed, or when a year or two old, may plant them out in rows a foot asunder.

By Roots.—As before observed, the roots may be procured in plenty from the places of their growth, taking them up when their leaves decay in summer, and plant them directly where they are to remain, three inches deep: here they will probably increase by off-sets, like other bulbous roots, which may be taken up every two or three years, at the proper season as above, in order to separate the off-sets, planting the whole again as soon as possible, placing the off-sets in beds by themselves.

When designed to cultivate these plants for use, the roots should be deposited in beds, in rows ten or twelve inches asunder, and the depth as above.

ORDO, an Order: the first sub-division of a class in the sexual arrangement of plants; and each class is subdivided into Orders, or secondary divisions, founded principally on the number of styles or female organs, and some other striking part of the fructification of flowers; and the Orders are divided into genera, &c.

Each Order is distinguished by a proper name, according to the number of styles, &c. for example, when one style, it is termed *Monogynia*; two styles, *Digynia*; three, *Trigynia*; four, *Tetragynia*; five, *Pentagynia*; many styles, *Polygynia*, &c. which names of the Orders are always subjoined to that of their respective classes, as well in all the different genera described in this work, immediately preceding the *Characters*, as under the article CLASSIS, which see.

The names of the Orders are often the same in different classes, because the same idea predominates in their institution. See CHARACTERS, CLASSIS, and GENUS.

ORIGANUM, Origany, or Marjoram.

This genus furnishes some under-shrubby perennials, and an herbaceous annual; all fine aromatics, some for the kitchen-garden, pleasure-ground, and green-house; rising with upright branchy stems, from six or eight inches to two feet high, garnished with oval and roundish leaves, and small monope-
talous

talous ringent flowers collected into spikes and heads, at the axillas and tops of the stalks.

Class and order, *Didynamia Gymnospermia*.

Characters.] CALIX, an involucre composed of oval, coloured leaves, placed imbricatum, with unequal perianthiums. COROLLA, one ringent petal, with a cylindric compressed tube, and the upper lip plane and emarginated, the lower one trifid. STAMINA, two long and two short filaments, and simple antheræ. PISTILLUM, a quadrifid germen, slender style, and bifid stigma. PERICARPIUM, none; four naked seeds, lodged in the bosom of the calix.

The principal species of our gardens, are two hardy perennials, and an annual for the open ground, and five perennials for the green-house.

Hardy Perennial Kinds.

¹ORIGANUM Vulgare.

Common Origany, or Wild Pot Marjoram.] Hath a fibrey perennial root; many upright, square, ligneous stems, branching half a yard or two feet high; closely garnished with oval, almost close-fitting, opposite leaves, with smaller ones from the axillas; and at the sides and ends of the branches, roundish, paniculated, conglomerated spikes of small pale-red flowers, having oval bractæa longer than the calix.

Varieties.] Purple-flowered—white-flowered—variegated-leaved.

²ORIGANUM Heracleoticum.

Heracleotic Origany, or Winter Sweet Marjoram.] Hath a fibrated perennial root; upright, four-cornered, purpleish stems, branching half a yard high; garnished with oval, obtuse, hairy, opposite leaves, on short foot-stalk; and at the axillas of the stems, long aggregate spikes of small white flowers, having the bractæa as long as the calix.

Variety.] Variegated-leaved.

Both the above hardy perennial *Origanums*, are finely-scented aromatics, excellent for culinary purposes, particularly for broths, soups, &c. they have likewise merit for medical uses, and for giving fragrance to ointments; so that the plants are proper both for kitchen and physic-gardens, and may also be employed in the pleasure-ground as plants of variety.

Annual Kind.

³ORIGANUM Marjorana.

Marjorana, or Annual Sweet Marjoram.] Hath a fibrous annual root; upright branchy

stems, rising a foot or fifteen inches high; small, oval, obtuse, hoary leaves; and the stem and branches terminated by roundish, compact, downy spikes of small white flowers.

This annual is an aromatic of the highest fragrance, is admirable for kitchen use, and is excellent for nosegays; so is proper both for the kitchen and pleasure-garden, but more particularly the former.

It is often called knotted Marjoram, from the flowers growing in close knotted-like heads.

Green-house Kinds.

The following mostly assume an under-shrubby growth; frequently with abiding stalks, if they have shelter here in winter.

⁴ORIGANUM Dictamnus.

Dictamnus, or Dittany of Crete.] Rises with slender, hairy, purple stalks, branching by pairs eight or ten inches high; garnished with round thick leaves, the under ones woolly; and the branches terminated by nodding spikes of purple flowers.

This species is a very strong aromatic.

⁵ORIGANUM Sipyleum.

Origanum of Mount Sipylus.] Rises with upright, four-cornered, smooth, purpleish stalks, branching by pairs near two feet high; oval smooth leaves; and all the branches terminated by oblong nodding spikes of purpleish flowers.

⁶ORIGANUM Creticum.

Cretan Origany, or Marjoram.] Rises with upright, four-cornered stems, branching a foot and a half high; oval, obtuse, hoary leaves; and the stalk and branches terminated by long, aggregate, prismatic spikes of small white flowers, having membranous bractæa double the length of the calix.

⁷ORIGANUM Smyræum.

Smyrna Origany.] Rises with upright, branchy, hairy stalks, a foot and a half high; oval, acutely serrated leaves; and umbellate-clustered spikes of white flowers.

⁸ORIGANUM Ægyptiacum.

Ægyptian Marjoram.] Rises with a shrubby stem, branching a foot and a half high; roundish, fleshy, hollowed, woolly leaves; and the stalks and branches terminated by roundish, naked spikes of pale-red flowers.

All these eight species of *Origanum* flower in July and August; the flowers are small, monopetalous, ringent, universally hermaphrodite, and collected into verticilli round the stalks; succeeded by ripe seed in autumn; though

though in this country the annual Marjoram and the three green-house sorts seldom perfect seed well, unless the autumn proves remarkably fine and warm: in default, however, of seed, the propagation of all the perennial sorts, both hardy and green-house kinds, is easily effected by slips of the roots, &c. And the seed of the annual sort is imported plentifully from France or Italy, by the seed-dealers.

Most of the species are remarkable for their agreeable aromatic fragrance and quality.

The first three sorts particularly, have great merit as culinary aromatics for the kitchen-garden, and may also be introduced into the pleasure-ground, in patches in the open borders to encrease the variety, and for nosegays, &c. the variegated perennial Marjorams in particular have a pretty effect; they are all easily raised from seed in the open ground in spring, and the perennial sorts also by dividing the roots; all of which sorts, both perennials and annuals, when designed for the kitchen-garden, should generally be disposed in four-feet-wide beds, the perennials in rows a foot asunder, where they will abide for years; and the annual sort being always raised from seed annually, it may either remain where sowed, or the young plants may be planted out in rows six or eight inches distance; and when designed to have any of the sorts in the pleasure-garden dispose them about the borders in patches.

But the last five species being exotics from warm countries; they require shelter here in winter, so must be potted and placed in the green-house collection, or may be preserved all winter in a common garden-frame, furnished with lights to put on in nights and cold weather.

Propagation, &c. of all the Sorts.

Their different methods of propagation are; the hardy perennial species by seed and by slipping the roots; the annual sort only by seed annually; and the five green-house kinds principally by slips and cuttings.

Two Hardy Perennial Sorts.—Both these hardy perennials may be propagated by seed, and by parting the roots.

By Seed.—This may be had at the seed-shops: sow it in spring, March or April, in any bed or border of light earth, and rake it in with a light hand; they will soon come up: when the seedlings are a few inches high, plant them out in moist weather, in rows ten or twelve inches distance, finally to remain, giving occasional waterings till fresh rooted.

By Parting the Roots.—Autumn is the best season, though it may also be performed successfully in spring. Having some large plants, slip or divide the roots into slips, each furnished with fibres; which plant in rows, as directed for the seedlings, giving occasional waterings, and they will readily grow, and become good bushy plants by autumn following.

Their general culture is the keeping them clean from weeds; and every autumn cut down all decayed stalks; loosen the earth between the plants; at the same time digging the alleys, spread a little of the earth over the surface of the beds.

When any are intended for the pleasure-garden, remove them in autumn or spring, with little balls of earth about their roots, and plant them where wanted.

Annual Sort.—This plant is raised by seed only: sow it annually in spring towards the latter end of March, or in April, on a warm dry border, and rake it in; or may be sowed in shallow drills: the plants will soon come up, and may either remain where sowed, thinning them to four or five inches distance; or when two inches high may be planted out in moist weather, in rows six inches asunder, giving a due supply of water till fresh-rooted, and they will soon cover the ground, and not need any farther culture.

When any are designed for the pleasure-garden, the seed may be sowed in patches where you would have them remain to flower.

Green-house Kinds.—All these sorts are propagated by slips or cuttings of the young shoots in spring and summer. If you plant them early, let it be in pots, and plunge them in any hot-bed, they will readily take root; but if in summer, they may be planted either in pots, or in a shady border. In either mode of planting, give water directly, which repeat as occasion may require in moderate quantities; and if those that are planted in the open air, either in pots, or in the full ground, are covered down with hand-glasses, it will facilitate their rooting; but the glasses must be removed when the plants begin to shoot at top: the plants in either way will be rooted the same year; and towards autumn may be potted off separately into small pots, and afterwards managed as other hardy green-house exotics.

ORNITHOGALUM, Star of Bethlehem.

This genus comprises several herbaceous, bulbous-rooted, flowery perennials, for adorning the pleasure-garden, and one for the green-

green-house collection; having all large bulbous roots, crowned mostly with long, narrow, carinated, and ensiforme leaves, and upright naked flower-stalks annually, rising from half a foot to a yard high in different sorts, terminated in long, large spikes of hexapetalous, star-shaped, white flowers.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, none. COROLLA, six spear-shaped petals, erect to the middle, and plane and spreading above, and are permanent. STAMINA, six erect filaments half the length of the corolla, and simple antheræ. PISTILLUM, an angular germen, awl-shaped permanent style, and an obtuse stigma. PERICARPUM, a roundish, angular, trivalvate, trilocular capsule, containing many roundish seeds.

Of this species there are cultivated in our gardens about six hardy species for the open borders, and one tender kind requiring shelter of a green-house, &c. in winter.

Hard Kinds, for the Open Ground.

¹ORNITHOGALUM *Pyramidale*.

Pyramidal, large-spiked, Portugal Star of Bethlehem.] Hath a very large, oval, bulbous root; crowned with long, keel-shaped, dark-green leaves; amidst them an upright, firm, naked flower-stalk, near a yard high; terminating in a very large, long, pyramidal spike of numerous, ascending, white, starry flowers; appearing in June.

²ORNITHOGALUM *Pyreniacum*.

Pyrenean Green-flowered Star of Bethlehem.] Hath a large onion-like bulbous root; crowned with long, keel-shaped, spreading leaves; an upright, naked flower-stalk, half a yard or two feet high, terminated by a very long spike of yellowish-green flowers on long spreading pedunculi, which as the fruit ripens becomes gradually erect, nearly approaching the stalk; flowering in May.

The flowers of this species possess an agreeable sweet scent. The plant is a native of the Pyrenian mountains; also of England, in some meadows, and by way-sides.

³ORNITHOGALUM *Latifolium*.

Broad-leaved Arabian Star of Bethlehem, sometimes called Alexandrian Lily.] Hath a very large, roundish, bulbous root; crowned with broad, long, sword-shaped leaves, spreading on the ground; an upright, thick, strong, naked flower-stalk, two or three feet high; terminating in a long, loose spike of many large, starry, white flowers, on long pedunculi; appearing in June.

This is a hardy exotic of Arabia and Ægypt.

⁴ORNITHOGALUM *Umbellatum*.

Umbelliferous Star of Bethlehem.] Hath a large, roundish, white, bulbous root; crowned with long, narrow, keel-shaped, white-streaked, spreading leaves; an upright, naked flower-stalk, five or six inches high, terminated by taller pedunculi; sustaining a corymbose umbel of white flowers, having the outside striped with green; appearing in April and May.

It grows wild in England, &c. in some woods and meadows.

⁵ORNITHOGALUM *Luteum*.

Yellow Star of Bethlehem.] Hath a small, roundish, bulbous root; crowned with two or three narrow, keel-shaped leaves; an upright, two-leaved flower-stalk, six inches high; terminated by a simple umbel of yellow flowers; appearing in April.

It grows wild in England, &c. on the borders of uncultivated fields, meadows, and pastures.

⁶ORNITHOGALUM *Nutans*.

Nodding Star-flower of Naples.] Hath a large, compressed, bulbous root; long, narrow, keel-shaped, dark-green leaves; an upright naked flower-stalk, about a foot high; terminated by a loose spike of flowers hanging on one side, white within, and of a greyish-green without, and with a stameneous, campanulated nectari. Flowering in April and May.

Of the above six hardy *Ornithogalums*, the first three are the most ornamental, and most noted sorts in the English gardens; the other three are also kept in many gardens for variety: all the sorts are exceeding hardy, and will prosper any where.

Tender Kind for the Green-house Collection.

⁷ORNITHOGALUM *Capense*.

Cape Ornithogalum.] Hath a large, irregular, tuberous, dark-brown root; crowned with heart-shaped-oval, ribbed leaves, elevated on foot-stalks; upright, slender, naked stalks, about a foot high; terminated by a loose spike of greenish-white flowers; appearing in October and November.

It is an exotic from the Cape of Good-Hope.

Variety.] With pale-blue flowers.

All these plants are perennial in root, but annual in leaves and stalks, which in the six hardy sorts rise annually in the spring, and flower

flower in their proper season: the flowers consist universally of six petals that expand themselves at top like the figure of a star; and being numerous in each spike, are very conspicuous; and in the tall sorts make a very ornamental appearance: succeeded in all the kinds by plenty of ripe seeds in autumn: this, however, is rarely wanted, for the plants propagate exceedingly by off-sets of the roots, which every second year, in summer when they have done flowering, and the leaves and stalks decay, may be taken up, and the off-sets separated for encrease.

The six hardy sorts are proper furniture for the pleasure-garden, placing the larger growing sorts in the most conspicuous parts, in assemblage with other bulbous flowers; planting the sorts in general three or four inches deep, and they may remain unremoved two or three years, when the roots will be increased by off-sets into large bunches, each exhibiting a large cluster of flowers.

And if some roots of the *Ornithogalum Pyramidale*, &c. are planted in large pots, one root in each, in order for moving occasionally to adorn any particular compartment, they, when in bloom, will have a fine effect.

The *Ornithogalum Capense* must be always kept in pots of light earth, for the convenience of moving them to the shelter of a green-house or garden-frames in winter.

The Propagation, &c. of all the Sorts.

The propagation of all the sorts is effected abundantly by off-sets of the roots.

The six hardy sorts in particular multiply by off-sets in great plenty, if they stand two or three years, especially the smaller sorts; the larger kinds also of some standing throw out off-sets abundantly enough for a plentiful increase; and the best season for removing all the sorts in order to separate the off-sets is July and August, when their leaves and stalks decay; and the roots may either be planted again in August or September, or kept till October or November, &c. but remarking the autumnal-planted bulbs will flower much stronger than those not planted again till spring. Observe to plant the off-sets in nursery-beds for a year, managing the whole as directed for other hardy bulbs. See BULBUS.

The Cape *Ornithogalum* is also propagated by slips or off-sets of the roots, which may be slipped when the leaves and stalks decay; planting each slip or off-set in a separate pot

of good light earth; and place them to have shelter from frost and excessive wet weather in winter, and in the full air in summer.

OROBUS, Bitter Vetch.

This genus consists of hardy, herbaceous, fibrous-rooted, very floriferous perennials for the embellishment of the pleasure-garden; rising with erect stems, from about one to two feet high, ornamented with winged leaves of from two to several pair of lobes; and at the axillas and top of the stalks, loose spikes and clusters of papilionaceous, purple and blue flowers of ornamental appearance.

Class and order, *Diadelphia Decandria*.

Characters.] CALIX, is monophyllous, tubular, and five-parted at the top. COROLLA, is papilionaceous, with a heart-shaped standard, two long connivent wings, a bifid, assurgent, acuminate keel, swollen at the base. STAMINA, ten diadelphous filaments, and oblong antheræ. PISTILLUM, a cylindric compressed germen, a bent style, and narrow downy stigma. PERICARPIUM, a long, taper, acute, unilocular pod, having many roundish seeds.

The plants of this genus are mostly natives of woods and commons in different parts of the world; but several of the sorts are retained in gardens for the beauty of their flowers.

The most material species are the following seven.

¹OROBUS *Vernus*.

Vernal Orobis.] Hath strong fibrated roots; upright simple stalks, rising a foot high; garnished with pinnated leaves of two pair of oval lobes, attended by half-arrow-pointed, entire stipula; and at the axillas short spikes of flowers of different colours in the varieties; appearing in March.

Varieties.] Purple-flowered spring *Orobis*—deep blue-flowered—pale blue-flowered.

²OROBUS *Tuberosus*.

Tuberous-rooted Orobis, sometimes called Wood Pea.] Hath a tuberous, knotty, creeping root; upright, angular, simple stems, about a foot long; pinnated leaves, of four pair of lanceolate lobes, attended by half-arrow-pointed stipula; and at the axillas long pedunculi, each having two or three reddish flowers; appearing in April and May.

It is a resident of shady woods in England and other countries.

³OROBUS *Lathyroides*.

Lathyroides, or Bastard Lathyrus.] Rises with upright branchy stems about a foot high; con-

conjugated, almost close-fitting leaves, having indented stipula; and at the axillas short pedunculi, each terminated by a short spike of bright blue flowers.

⁴*OROBUS Lunata.*

Lunated Siberian Orob.] Rises with upright, unbranching stalks, a foot and a half high; pinnated leaves, of four or five pair of oval-oblong lobes, attended by broad lunated or moon-shaped stipula; and at the axillas short pedunculi supporting large purple flowers; appearing in April.

⁵*OROBUS Sylvaticus.*

Sylvian, or Wood Orob.] Rises with decumbent, branching, hairy stalks, a foot and a half long; winged leaves of seven pair of lobes; and at the axillas close spikes of purple flowers; appearing early in June.

This grows naturally in woods in several parts of England.

⁶*OROBUS Niger.*

Black Orob.] Rises with upright branchy stems, two feet high; pinnated leaves, of six pair of oval-oblong lobes; and at the axillas long pedunculi, each supporting several purple flowers; appearing in May.

⁷*OROBUS Pyreniacus.*

Pyrenean Orob.] Rises with upright, branchy stems, a foot and a half high; pinnated leaves, of two pair of spear-shaped nervous lobes; and at the axillas long pedunculi, terminating in loose spikes of purple flowers; appearing in May.

All these seven species of *Orob.* have strong fibrated roots, which are perennial, but are annual in stalk; rising early in spring and decay in autumn.

They are all very hardy plants, and prosper in any common soil of a garden.

Most of the sorts are very floriferous, and the flowers conspicuous and ornamental for adorning the flower compartments; the flowers are universally of the papilionaceous or butterfly kind, consisting each of four irregular petals, i. e. a standard, two wings, and a keel; and are all succeeded by long taper seed-pods, furnishing plenty of ripe seed in autumn; by which the plants may be propagated abundantly, as also by parting the roots.

With respect to their merit in gardens, they may be employed in any of the compartments of the pleasure-ground as flowery plants: they will flourish any where and exhibit a pretty variety when in flower.

Their Propagation, &c.

Their propagation is by seed and by parting the roots.

By Seed.—All the sorts furnish plenty: sow it in autumn, i. e. September, or beginning of October, or early in spring, in any bed or border, and rake them in, and those of the autumn-sowing will readily come up in spring; but those of the spring-sowing do not come up so freely: as the plants advance, clear them from weeds, and give occasional waterings; and in June or July, when a few inches high, prick them out, in moist weather, in nursery-rows half a foot asunder, to remain to gain strength till October or November, then transplant them where they are to remain.

By parting the Roots.—Autumn, when their stalks decay, is the best time for this: having recourse to some large plants, divide the roots into slips, each furnished with fibres, and plant the largest at once where they are to remain; and the smallest may be planted in nursery-rows for a year.

OSTEOSPERMUM, Hard-seed, commonly called Hard-seeded *Chrysanthemum*.

This genus furnishes shrubby exotics for the green-house collection, rising with shrubby durable stems, branching several feet high, garnished with oval and spear-shaped leaves; and the branches terminated by yellow compound flowers.

Class and order, *Syngenesia Polygamia Necessaria*.

Characters.] *CALIX*, a compound flower, having a simple, hemispherical, many-parted cup. *COROLLA*, a compound radiated flower, of many small florets, being funnel-shaped, males or hermaphrodites in the disk or middle, and flat tongue-shaped females in the radius. *STAMINA*, in the hermaphrodites five very short filaments, and cylindric antheræ. *PISTILLUM*, in the hermaphrodites a small germen, slender style, and obsolete stigma, and in the females a globular germen, slender style, and an emarginated stigma. *PERICARPIUM*, none, in each female floret a single seed, as hard as bone.

The plants of this genus are mostly natives of Africa, and require shelter of a green-house here in winter.

The species are:

¹*OSTEOSPERMUM Moniliferum.*

Moniliferous Ethiopian Osteospermum.] Hath a shrubby stem, branching six or eight feet high,

high, having a smooth grey bark; oval, ferrated, thick, hoary, alternate leaves, on decurrent foot-stalks; and the branches terminated by clusters of yellow flowers.

²*OSTEOSPERMUM Pisiferum.*

Pisiferous Cape Osteospermum.] Hath a shrubby stem, branching seven or eight feet high, having soft woolly branches; spear-shaped, pointed, ferrated, smooth leaves, on very short, bordered foot-stalks; and the branches terminated by clusters of yellow flowers.

³*OSTEOSPERMUM Spinosum.*

Spinous African Osteospermum.] Hath a low shrubby stem, branching three or four feet high, armed with branchy spines; oblong, narrow, clammy leaves, placed irregularly; and the branches terminated by yellow flowers singly.

⁴*OSTEOSPERMUM Polygaloides.*

Polygaloides Ethiopian Osteospermum.] Hath a shrubby stem, branching four or five feet high; spear-shaped, entire, smooth, decurrent leaves, placed almost imbricatum; and the branches terminated by yellow flowers singly.

All these *Osteospermums* are durable in root, stem and branches, retaining their leaves most part of the year: the first sort is that which is the most common in the English gardens. They flower in summer; the flowers are universally compound and radiated; rarely succeeded by good seeds in England.

The plants must always be kept in pots for moving to shelter of a green-house in winter, and managed as myrtles and other green-house shrubs.

Their propagation is by cuttings any time in summer. Chuse the young shoots, which plant in pots, several in each, giving water and occasional shade, for a month or six weeks, when they will be rooted; and before winter should be potted off separately, and placed among the other green-house exotics.

OTHONNA, African Ragwort.

The plants of this genus are shrubby and undershrubby ever-green exotics of Africa, for the green-house, rising from about two to four or five feet high, ornamented with pinnatifid and entire spear-shaped leaves, and the branches terminated by compound radiated yellow flowers.

Class and order, *Syngenesia Polygamia Necessaria*.

Characters.] *CALIX*, a compound radiated flower, having a single monophyllous cup,

divided into eight or twelve parts. *COROLLA*, a compound radiated flower, of numerous small florets, the middle or disk composed of many tubular hermaphrodite florets, and the ray of eight or twelve flat, tongue-shaped, tridented, female florets. *STAMINA*, in the hermaphrodite florets five short filaments, and long cylindric antheræ. *PISTILLUM*, an oblong germen, slender style, and in the hermaphrodites a simple bifid stigma, which in the females is large and reflexed. *PERICARPIUM*, none, each female floret is succeeded by one oblong seed, crowned with down, lodged in the permanent calix.

The most noted species are;

¹*OTHONNA Pectinata.*

Pectinated-leaved Othonna.] Hath a shrubby stem, branching numerously two or three feet high, the branches covered with a hoary down; oblong, pinnatifid, hoary, white leaves, being cut pinnatifid-wise almost to the mid-rib, into many narrow parallel segments, arranged in a pectinated manner, or resembling the teeth of a comb; and at the axillas and ends of the branches long pedunculi, terminated by large yellow flowers, with spreading rays.

²*OTHONNA Abrotanifolia.*

Abrotanum-leaved Othonna.] Hath a low, shrubby, jointed stem, branching about two feet high; thick, finely multifid-pinnated, southernwood-like leaves; and the branches terminated by yellow flowers.

³*OTHONNA Coronopifolia.*

Coronopus-leaved Othonna.] Hath a shrubby stem, branching four or five feet high; spear-shaped, narrow lower leaves, the upper ones sinuated and indented; and the branches terminated by umbellate clusters of yellow flowers.

These shrubs flower in summer and autumn: the flowers are in general compound and radiated, continuing in succession two or three months, but are rarely succeeded by good seed in our gardens.

They are proper furniture for the green-house collection, and being tender must always be kept in pots for moving to shelter in winter; they will have a very pretty effect in this collection, both by their mode of growth, leaves, and flowers: managing them generally as directed for other shrubby exotics of the green-house. See *GREEN-HOUSE PLANTS*.

Their propagation is by slips and cuttings of the young shoots, planted any time in summer,

summer, before the latter end of July, either in pots, or in a bed or border, watered and shaded occasionally from the sun, till rooted, which they will effect the same season; or

if they are covered close with hand-glasses and shaded, it will facilitate their rooting: early in autumn pot them separately, and manage them as other green-house shrubs.

P.

PÆONIA, Peony.

This genus furnishes large herbaceous flowery perennials, mostly of the tuberous-rooted kind; having roots composed of large fleshy tubers, sending up strong annual stalks, from one or two to three feet high; garnished with large, many-lobed, spreading leaves; and terminated by very large, pentapetalous, polyandrous flowers.

Class and order, *Polyandria Digynia*.

Characters.] CALIX, five roundish, concave, reflexed, equal leaves. COROLLA, five large, roundish, concave, spreading petals. STAMINA, numerous short capillary filaments, and large, oblong, quadrangular, erect antheræ. PISTILLUM, two or three downy germina, no styles, but oblong compressed obtuse, coloured stigmas. PERICARPIUM, two or three oval-oblong, spreading, reflexed, downy, univalvular, unilocular capsules, having many oval seeds.

There are only two species, one of which, however, common Peony, admits of many elegant varieties, with both single and double flowers; but the doubles being remarkably large, and the petals multiplied in many series to the very centre, are considerably more beautiful and estimable than the singles, which have only five petals, according to their *characteristic* description; but the petals are innumerable in the double varieties, forming a fine full flower; much larger than the biggest double rose.

The species are;

¹PÆONIA *Officinalis*.

Common Officinal Peony.] Hath a large root, composed of many thick fleshy tubers, hanging by strings to the main head; upright, round, robust, smooth stalks, branching half

a yard or two feet high, or more; garnished with very large, many-lobed leaves, composed of oblong-oval folioles, spreading widely all around; and the stalk and branches terminated by large, deep-red flowers singly, having numerous stamina, with yellow antheræ; surrounding two, three, or more germina, succeeding to so many capsules, opening longitudinally, and discover their seed, gradually ripening to a dark-purple, or blackish colour. Flowering in May and June.

Of this species there are two noted varieties, called, Male Peony, and Female Peony; each of which comprehending also some varieties, viz.

Male Peony.]—Hath lobated, dark-green leaves, having large oval folioles cut on the sides; and very large, single, red flowers; succeeded by capsules remarkable for turning backward, opening and displaying their red inside, together with the numerous seeds in a singularly agreeable manner, appearing very ornamental after the flower is past.

Female Peony.]—Hath unequally lobated pale-green leaves, with narrow lobes, more frequently cut on the edges, and smaller deep-purple flowers.

Of these two principal Varieties are the following;] Double red-flowered—double deep-red-flowered—double purple-flowered—double rose-coloured—double white-flowered—double black-flowered—Portugal deep-red sweet-scented Peony—Constantinople large blood-red Peony—dwarf white Peony.

All these sorts, considered as flowery plants, are very ornamental in their flowers, particularly the doubles.

The plants have also great merit for medicinal uses.

PÆONIA Tenuifolia.

Narrow-leaved Peony.] Hath a thick, fleshy, creeping root; upright unbranching stalks, rising a foot and a half high; smallish multipartite leaves, having the lobes divided into a multitude of narrow segments; and the stalks terminated by red flowers placed singly.

Both these species of *Pæonia*, and all the varieties, are perennial in root, but annual in stalk and leaves; rising in spring, form large bushy plants, having the flowers erect in the midst of them; and wholly die gradually to the ground at the approach of winter.

They flower in May and June, continuing in beauty a month or six weeks: the flowers are very large in the first species and varieties; and in their single or *characteristic* state, in all the sorts, consist of five large roundish petals; but in the doubles the petals are multiplied in many series inward to the centre, forming very large full flowers, which in most of the sorts are succeeded by plenty of ripe seed in autumn, by which the plants may be raised in the common ground in great abundance, as well as by off-sets of the roots. See their *Propagation*.

All the sorts are hardy plants that will flourish in any common soil of a garden in almost any situation, either in open exposures, or under shade of trees, &c. and will abide by the roots a great number of years, flower annually, and encrease exceedingly by off-sets for propagation.

They are proper ornaments as flowery plants, for large borders and other compartments, and may be had at all the public nurseries. Observing that the best season for removing them is in autumn, when their stalks and leaves are decayed; planting one here and there in different parts, placing them with the crown of the root a little within the surface of the earth, and at a yard at least distance from other plants, for they extend themselves widely every way, assuming a large bushy growth; which, together with their conspicuous large flowers, exhibit a fine appearance.

After the flowers are gone, the capsules opening lengthways, discover their coloured seeds very ornamentally, especially the Male Peony and varieties; and to forward this, some slit the capsules open on the inside at the proper valve, whereby they will expand

much sooner, and display their beautiful seed.

The plants may be suffered to remain several years unremoved, till the roots are encreased into very large bunches, and may then be taken up, when the stalks decay, in autumn, and divided.

Their Propagation, &c.

Their propagation is effected most commonly by dividing the roots; but they may also be raised abundantly from seed.

By dividing the Roots.—The roots multiply fast by off-sets; and the best time for removing and separating them is August and September. When the stalks are decayed, then the whole root may be taken up and divided, each slip or off-set, having at least one eye or bud at its crown, will make a proper plant. I would not, however, advise dividing them into very small slips, unless when as great an encrease as possible is wanted: in which case they may be divided as small as may be, provided each set is crowned with one or more buds; and in either case it is advisable they be all planted again soon after; for although these roots, if removed at the proper time as above, may upon occasion be kept out of the ground some time, yet when planted again soon after their removal, they will flower much stronger; observing, you may plant the larger off-sets at once where they are to remain; and the smaller ones in nursery-beds to stand a year or two to gain strength, then transplanted into their places of final destination.

By Seed.—All the single-flowered kinds in particular produce plenty, and from which both single and double-flowered plants are obtained. Autumn, soon after the seed is ripe, is a very successful season for sowing; though it may also be performed in spring, and may be sowed in any bed or border of light earth, either by broad-cast, and raked in, or in shallow drills, six inches asunder, covering the seeds half an inch deep: they will readily come up in April or May; keep them clean from weeds, and give moderate waterings in dry weather; and as it is proper they should remain two seasons in the seed-bed, it is advisable in autumn to spread an inch depth of light earth over the surface of the bed: the next year, in September, transplant them where they are to remain.

PANCRATIUM (*Pancratium Lily*) Sea Daffodil.

This

This genus consists of large bulbous-rooted, herbaceous, flowery perennials, of very ornamental appearance for the pleasure-ground and stove collection, having very large bulbous roots, crowned with long leaves, some very narrow, others broad; and upright robust flower-stalks, from one to two or three feet high, terminated by a large spatha, or sheath, protruding some many, others but one or two hexapetalous, liliaceous, white flowers, of great beauty and fragrance.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, an oblong spatha, opening on one side, protrudes many flowers, and withers. COROLLA, six spear-shaped petals, and in the middle a monopetalous, funnel-shaped nectarium, ten or twelve-parted, and spreading at top. STAMINA, six awl-shaped filaments inserted into the brim of the nectarium, and oblong incumbent antheræ. PISTILLUM, an obtuse trigonal germen under the corolla, long filiforme style, and an obtuse stigma. PERICARPIUM, a roundish, trigonous, trilocular capsule, having many globular seeds.

Of this genus there are two hardy species for the pleasure-garden, and five tender kinds for the stove.

Hardy Kinds.

¹PANCRATIUM *Maritimum*.

Maritime Pancratium, or Common Sea Daffodil.] Hath a very large, oblong, bulbous, dark-coated root; crowned with tongue-shaped leaves a foot-long, encompassed at bottom with a sort of sheath; amidst them an upright, robust, naked flower-stalk, a foot and a half high, surmounted by a multiflorous spatha, protruding several large white flowers, having plane petals. Flowering in the latter end of August or in September.

It grows naturally on the sea-coast of France and Spain.

²PANCRATIUM *Illyricum*.

Illyrian Multiflorous Pancratium.] Hath a large, oval, bulbous, dark-coated root; crowned with sword-shaped leaves, a foot and a half long, and two inches broad; an upright, thick, succulent, naked flower-stalk, near two feet high; terminated by a multiflorous spatha, protruding six or eight white flowers, having the stamina longer than the nectarium. Flowering in June and July.

Both these hardy *Pancratiums* prosper in the open ground, but must have a warm dry situation, and a light soil, and sheltered occa-

sionally from severe frost, where they will abide for many years by the root, renewing their leaves and flower-stalks annually, and encrease freely by off-sets.

Tender Kinds for the Hot-house.

These sorts being tender exotics from the warm parts of the Indies, in this country must be kept in pots, in order for being placed always in the hot-house, where they will exhibit their beautiful fragrant flowers at different times of the year.

³PANCRATIUM *Zeylanicum*.

Ceylon Uniflorous Pancratium.] Hath a large oval, bulbous root, crowned with narrow erect leaves, a foot long; an upright, firm, naked flower-stalk, fifteen or eighteen inches high, terminated by a uniflorous spatha, protruding one large white flower, having reflexed petals.

⁴PANCRATIUM *Mexicanum*.

Mexican Biflorous Pancratium.] Hath a large bulbous root; crowned with furrowed leaves, a foot long, and two or three broad; an upright naked flower-stalk, about a foot high; terminated by a biflorous spatha, protruding two large white fragrant flowers.

⁵PANCRATIUM *Caribbæum*.

Caribbæan Multiflorous Pancratium.] Hath a very large bulbous root; crowned with spear-shaped, moderately-broad, longitudinally-ribbed leaves; an upright, thick, firm, naked flower-stalk, two feet high, or more; terminated by a multiflorous spatha, protruding many very large, white, fragrant flowers.

⁶PANCRATIUM *Amboinense*.

Amboyna Broad-leaved Multiflorous Pancratium.] Hath a large, oval, white, bulbous root; crowned with oval, nervous, or deeply ribbed leaves, seven or eight inches long, and five or six broad, growing on short foot-stalks; and an upright, thick, naked flower-stalk, near two feet high, terminated by a multiflorous spatha, protruding many large white flowers.

Variety.] With broad, oval, acuminate leaves, and very fragrant flowers.

⁷PANCRATIUM *Carolinianum*.

Carolina Multiflorous Pancratium.] Hath a roundish, bulbous root; crowned with very narrow leaves, a foot long; and an upright, robust, naked flower-stalk, eight or nine inches high, terminated by multiflorous spatha, protruding several flowers, having the stamina as long as the nectarium.

All.

All these plants are perennial in root, but annual in stalk, which always decay soon after the flower is past.

Their season of flowering is different, the two hardy sorts flower here pretty constantly at the times mentioned in their description; and as to the tender kinds, they often exhibit their flowers in our stoves in the middle of winter, sometimes in spring, summer, and autumn; and sometimes they flower two or times a year, so that one or other of them exhibit flowers at almost all seasons. The flowers of all the sorts consist each of six petals, and a monophyllous nectarium in the centre, and are very ornamental, and most of them exceedingly fragrant; but rarely any of the sorts, except the *Panocratum Illyricum*, furnish ripe seeds in these parts.

They all encrease in tolerable plenty in root by off-sets for propagation.

All the sorts have great elegance in their flowers, and most of them are enriched with a delightful fragrance, and demand our attention for culture in the pleasure-garden and stove.

The two hardy sorts are proper for the pleasure-garden, but should have a warm dry situation, and light soil: the season for planting them is autumn, that is, the roots being taken up when their leaves decay, should be planted again soon after; placing them about four inches deep, and they will flower the year following; suffering the roots to remain unremoved two or three years; when they will be encreased by off-sets, and should be taken up and separated. See their *Propagation*.

Observe, in severe frosts it will be proper to cover the ground over the roots with litter, to protect them.

The five tender species must be planted in large pots, and placed in the hot-house: the season for planting and transplanting them is when their leaves decay: observe this, and plant one root in each pot, which plunge in the bark-bed of the stove, where let them always remain; and here they will flower strong at their usual seasons, and multiply exceedingly by off-sets.

Propagation of all the Sorts.

All the sorts are propagated by off-sets of the root, like other bulbs, which may be separated every second or third year, or according as they multiply; the proper time for which is when their leaves decay; planting

the off-sets of the hardy sorts in nursery-beds for a year, then transplanted where they are to remain; and those of the tender kinds plant in separate pots, plunging them in the bark-bed. Those of all the sorts will flower in perfection the second year, and in their turn furnish a proper supply of off-sets for encrease.

PAPAYER, Poppy.

The plants of this genus are hardy, herbaceous, fibrous-rooted, flowery plants; principally annuals and perennials, for ornament in gardens, and for medicinal use; rising with upright stalks, from one to three feet high, garnished with large, deeply jagged and pinnatifid leaves, and terminated by large tetrapetalous polyandrous flowers.

Class and order, *Polyandria Monogynia*.

Characters.] CALIX, is oval, and composed of two oval, concave, indented leaves that soon fall off. COROLLA, four large, roundish, plane, spreading petals. STAMINA, numerous shortish filaments, and oblong, compressed erect antheræ. PISTILLUM, a large roundish germen, no style, but the germen crowned by a target-shaped, plane, radiated stigma. PERICARPIUM, a very large, roundish, or oval, unilocular capsule, crowned with a plane stigma, opening under it in several places, and is filled with numerous small seeds.

There are eight or nine species, and of which four only have claim to attention as garden plants; two annuals, and two perennials: the two former of which comprise many varieties in respect to the size, various colourings, variegations, and doubleness of their flowers, some of which are very beautiful, though all of them rather of a disagreeable scent, and of short duration: the plants, however, are designed by nature for excellent purposes in medicine; and both the annual and perennial kinds may be employed to encrease variety in the pleasure-garden; they are all very hardy and prosper any where.

Annual Kinds.

PAPAYER Somniferum.

Somniferous common Garden Poppy.] Rises with an upright smooth stalk, dividing and branching a yard or more high; garnished with large, deeply jagged, amplexicaule, smooth leaves; and terminated by large, spreading, dark-purple, and other coloured flowers in the varieties, having smooth cups and capsules. Flowering in June and July.

The

The varieties of this species are numerous; many of which have great beauty, both in their amazing size, doubleness, and colourings.

Varieties of this are.] Double purple-flowered—double red-flowered—double white-flowered—double variegated purple-and-white-flowered—double variegated red-and-white-flowered—double red-and-white spotted-flowered, or carnation Poppy—double curled-flowered—double fringed-flowered—double feather-flowered—and also with single flowers of each sort.

Observe that as there are both single and double flowers of all the above varieties, the singles having only four petals, have no merit as garden-flowers; but the double kinds being very large, and the petals numerous, forming a handsome full flower, exhibit a good variety in a garden: the flowers, however, are but of very short duration, and in general of a disagreeable scent.

Most of the varieties of this species are of a somniferous nature, i. e. causing sleep: hence it is termed *PAPAVER Somniferum*.

The white officinal Poppy, a variety of this species, is the principal medicinal sort; it often grows five or six feet high, having large flowers, both singles and doubles, succeeded by very large heads, or capsules, as big as oranges, filled with very numerous seeds (about 8000); and the heads are greatly used in medicine; of which is made the *diacodium* of the shops; likewise from the heads is extracted the *opium* in Turkey; and any part of the plant boiled in water, and sweetened with sugar, causes sleep; but should be used with caution, because too large a quantity brings on death. The seed is also good in fevers and inflammatory disorders; so that this variety in particular is propagated in great plenty for supplying the shops.

All the varieties are raised commonly from seed in the open ground.

²*PAPAVER Rhæas.*

Rhæas, or Wild Globular-headed Poppy.] Rises with an upright, hairy, multiflorous stalk, branching a foot and a half high; garnished with long, pinnatifid, deeply-cut, hairy leaves; and the stalk terminated by many red and other coloured flowers in the varieties; succeeded by globular smooth capsules. Flowering in June.

This species is the wild red Poppy of the fields, but being improved by garden-culture, many varieties of different beautiful colours,

and exceeding doubleness, have been obtained.

Varieties are.] Double red-flowered—double purple-flowered—double white-flowered—double variegated-flowered of many fine-coloured varieties—and with single flowers of all the above colours and variegations.

Of the above varieties of this species, the double kinds only merit attention as flower-plants; the variegated sorts in particular are very beautiful; but all the flowers of the varieties, like those of the somniferous kind, are but of short duration.

Perennial Kinds, with durable Roots, but annual Stalks.

³*PAPAVER Cambricum.*

Cambrian, or Welsh Poppy.] Hath a perennial root; crowned with pinnated, cut leaves; upright, smooth, multiflorous stalks, a foot and a half high; garnished with small pinnated leaves; and terminated by many large yellow flowers; succeeded by oblong, smooth capsules. Flowering in June.

It grows spontaneously in Wales and some other parts of Britain.

⁴*PAPAVER Orientale.*

Oriental Poppy.] Hath a large, thick, perennial root; crowned with long, pinnated, sawed leaves; upright, rough, uniflorous stalks; terminated each by one large, deep-red flower; succeeded by oval smooth capsules. Flowering in May.

Variety.] With double flowers.

All these species of *Papaver* flower principally in June and July, except the oriental kind, which commonly flower in May: the flowers of all the sorts are large, particularly the annuals, and in their single state, consist each of four large, roundish petals; but the double flowers are composed of numerous petals, in several degrees of luxuriance in different varieties, and in all the sorts are succeeded by very large roundish capsules filled with numerous very small seeds, ripening in autumn.

As to their merit as garden-plants and propagation, observe as follow:

Annual Sorts.—Both these sorts furnishing many varieties with ornamental flowers, the doubles of which in particular make a pretty appearance in the compartments of the pleasure-garden, when disposed here and there in patches, so that we should procure seed of the finest doubles only, which may be sowed in autumn or spring, at once where the plants are

to remain, in patches as above, covering it near a quarter of an inch deep; and when the plants are come up an inch or two high, thin them where too thick, to three or four in each patch: here they will flower abundantly; observing, when the flowers appear, to cut out all such plants whose flowers are of bad colours, and all singles and half doubles; leaving only the fine full double flowers: thus by preserving only the best flowers, the blow will be ornamental; and will ripen plenty of seed, which, if permitted to scatter, numbers of plants will rise naturally.

The flowers, however, of all these annuals are but of a short continuance, which in very hot weather, are often but of one day's duration, but are succeeded by others on the same plant; the large doubles having numerous petals, they, by falling daily, cause a littering appearance.

When designed to cultivate the somniferous kinds for use, may sow the seed by broadcast, in any open ground, and rake them in; and when the plants are three inches high, hoe them out to a foot distance, there to stand to perfect their seeds.

Perennial Sorts.—Both these sorts are employed to form variety in large gardens; they may be placed any where, and plants of both sorts may be procured at the nurseries: in autumn or spring, planting them directly where they are to remain.

These two sorts may be propagated by seed and by parting the roots.

By Seed.—Sow it in autumn, or early in spring, in any bed or border, and rake it in; when the plants are three or four inches high, plant them out in nursery-rows to remain till autumn, then transplant them where they are finally to remain, and will flower in summer following.

By Roots.—In autumn or early in spring you may slip the roots, preserving fibres to each slip, which planted become proper plants, and will flower the following season.

PANICULA, Panicle; a mode of flowering, in which the common flower-stalk branches into several smaller, dispersed along its sides; and these smaller ones are again variously sub-divided into others; each division supporting flowers and fruit, hanging loosely; such as a head of oats, and many other plants.

A Panicle is of two sorts, diffuse, and coarctate.

A diffuse Panicle (*Panicula diffusa*) is when the partial flower-stalks, or pedicles, diverge, and the fructifications hang loose, so as to form in the whole a spreading loose panicle.

A coarctate Panicle (*Panicula coarctata*) is when the pedicles approach pretty close together, so as to form a narrow straight panicle.

PAPILIONACEUS Flos; a butterfly-shaped flower, such as all the pea-bloom kinds. See COROLLA *Papilionacea*.

A Papilionaceous, or butterfly-shaped flower, consists of four or five very irregular petals; and from their figure and position, bear an obvious resemblance in most of the genera, to a butterfly expanding its wings for flight; exemplified in all the sorts of pea, bean, kidney-bean, laburnum, &c.

The different petals of a Papilionaceous flower are characterized by distinct names; the upper one commonly the largest, and standing erect, is termed the standard, (*vexillum*;) the two side petals the wings, (*alæ*;) and the lowermost, which is generally concave, and united and divided at bottom, is called the keel, (*carina*;) from its resemblance to the keel of a boat; is sometimes of one petal, and sometimes two united.

Plants of the Papilionaceous tribe consist both of herbaceous plants and trees; and are of the class and order *Diadelphia Decandria*. See CLASSIS.

Some Papilionaceous flowers are of various sizes in different plants; some have very large petals, others middling, and others very small; and some are furnished with the standard only, as in the genus *Amorpha*; and in some the different petals are so situated as to form the appearance of a regular flower, whereby the Papilionaceous, or butterfly-shape, is not very conspicuous; far the greater part, however, have all the proper petals, representing the above form.

All the Papilionaceous flowers are hermaphrodite, and have commonly ten united stamina, generally *Diadelphous*, or of two sets; one set is composed of nine stamina in one crooked body, terminated by nine antheræ; and the second set consists of one filament only, lying along the cleft of the large bundle; sometimes separate, or totally distinct, and sometimes pretty closely attached: in the midst is a slender crooked style, crowned by a downy stigma,

stigma; succeeded by that sort of seed-pod termed legum (*legumen*) such as the pea, bean, kidney-bean, &c. being oblong, more or less compressed, with two valves, and one, two, or more, *loculi* or cells, containing a few seeds, of different shapes and magnitudes in different genera, all fastened along one suture, or seam, only. See LEGUMEN and PERICARPIMUM.

Papilionaceous-flowered plants are very numerous, and consist both of herbaceous plants and trees, as aforesaid: of the former many are trailing or climbing plants, with long weak stalks, and being as it were helpless of themselves, indulgent nature has either provided them with tendrils to climb and fasten themselves to the neighbouring trees and bushes, as in all the sorts of peas; or their stalks are endued with a faculty of twining themselves around the bodies in their neighbourhood for the purpose of support. The climbing sorts of kidney-bean furnish examples; and as to the tree and shrub kinds of this tribe, they obtain in stature, from one yard to sixty or seventy feet. Most of the sorts, both of the herbaceous and the shrub and tree kinds, are garnished with alternate leaves of different forms, being either simple, fingered, or winged, but most commonly of this last form, having the lobes entire, and sometimes placed in pairs, as in *lathyrus*, but most commonly the winged leaf is terminated by an odd lobe; and the winged or pinnated leaves of this order, have generally a daily, or periodical motion, depending upon the progress of the sun in his diurnal course. See MOTUS.

The principal plants of this tribe are the following, consisting of herbaceous plants and trees.

Amorpha, bastard indigo—*anthyllis*, ladies finger—*ebenus*, ebony of Crete—*erythrina*, coral-tree—*genista*, single-seeded broom—*lupinus*, lupine—*ononis*, rest harrow—*spartium*, common broom—*ulex*, furz or whins—*eschynomene*, bastard sensitive-plant—*colutea*, bladder-sena—*coronilla*, jointed-podded *colutea*—*cytisus*, laburnum, base-trefoil, &c.—*glycine*, Carolina kidney-bean-tree—*glycyrrhiza*, liquorice—*medysarum*, French honey-suckle—*lathyrus*, everlasting-pea—*lotus*, bird's-foot trefoil—*medicago*, moon and snail trefoil—*orobus*, bitter vetch—*phaseolus*, kidney-bean—*pisum*, pea—*robinia*, false acacia—*scorpiurus*, caterpillar-plant—*trifolium*, trefoil—*vi-*

cia, vetch and garden-bean—*astragalus*, liquorice-vetch, goat's-thorn—*piscida*, dog-wood-tree.

Several of the plants of this tribe or family, furnish food both for men and quadrupeds: the chief esculent sorts for the kitchen-garden are pea, bean, and kidney-bean; the seed of which are the eatable parts, also the young seed-pods of all the kidney-bean kinds.

Many of them are also useful plants for ornamenting gardens; and for many excellent medicinal uses; also many of them are valuable in various trades.

But the particular description of the different genera of this order, together with their uses and general culture, is fully illustrated, each under its proper head.

PAPPUS, Down of flowers, or a sort of feathery crown, which adheres to many kinds of seeds, exemplified in lettuce, dandelion, sow-thistle, groundsel, &c.

Many of the Pappose plants produce compound flowers, and their seeds are furnished with a *Pappus* adhering to the top of each, so as to resemble a shuttle-cock, and naturally framed for flying, for the purpose of dissemination or spreading about the seed, and for being transported by the wind to very considerable distances from its parent; an admirable contrivance of nature to sow her productions; and thus render common to different soils and territories individuals of the same species, which without such precaution might have been confined to one.

The *Pappus* is either simple, like hairs, *Pappus pilosus*, as in swallow-wort, groundsel, golden-rod, &c. or branched, or compound in a feathered-like manner, *Pappus plumosus*, as in dandelion, hemp-agrimony, scorzonera, and valerian: in some plants the *Pappus* adheres close to the seed, *Pappus sessilis*, as in hawkweed; and in some it is elevated upon a pedicle, or stipes, *Pappus stiptatus*, as in lettuce, dandelion, bastard-hawkweed; and the foot-stalks, or threads upon which it is raised, have obtained the name *stipes*. See STIPES.

Of this tribe of Pappose plants are many of our most cumbersome weeds, the seeds of which by the means of the *Pappus* are disseminated widely about our gardens and fields, particularly groundsel, thistle, sow-thistle, and dandelion; therefore the utmost care is requisite to destroy all these kind of weeds before they perfect seeds.

PARASITUS *Planta*, Parasitic Plants; plants that are produced upon the trunk or branches of other plants, and will not grow in the ground, such as mistletoe, and numbers of the mosses, and fungus tribe.

The manner in which Parasitic Plants attach themselves to others is not uniform, some, such as the mistletoe, mosses, and fungusses, are produced originally upon the plant on which they are found growing; the former of which grows upon the branches of large trees, principally from the under side of the branches, extending their roots under the bark, and branch out into a large spreading head, which generally grows downward, in a hanging position; and is nourished wholly at the expence of the tree upon which it grows; but the mosses are often dispersed all over the surface of the stem and branches; and the funguses grow sometimes on the upper roots of old trees, and sometimes upon their trunk or stem.

Other Parasitic Plants arise from the ground, and the stem attaches itself to the first plant it encounters, strikes root therein; after which the first root dies, and the plant continues to live and nourish itself upon the plant on which it is fixed.

There are other sorts of Parasitical Plants, which rooting first in the ground, their stems attach themselves to the bodies of trees in their neighbourhood, planting their roots into the bark, as they ascend; continuing, however, their ground-root, and draw their principal nourishment from the soil, exemplified in the *bedera*, or ivy-tree.

PARTERRE, a spacious level plot of ground in the pleasure garden, divided into many little partitions, or compartments, of different figures and dimensions; by means of edgings or lines of dwarf-box, or by verges of grass turf, and tracks of sand, fine gravel, &c.

These Parterre works were in great estimation in ancient gardening, and were commonly situated directly in the front of the house, generally the whole width of the front, and extended proportionably in length; and when the intermixture of the figures are artfully disposed, they strike the eye very agreeably, and afford an ornamental prospect at all times of the year.

The general figure of a Parterre is an oblong, or long square; about as long again as broad: choosing generally a level open spot

on some conspicuous part; and in the distribution, there is first a long bed or border of earth, carried all round for a boundary; and the internal space within this border, is traced out into various little partitions, or inclosures artfully disposed into different figures corresponding with one another, such as long squares, triangles, circles, various scroll-works, flourishes of embroidery, and many other devices, according to fancy; all of which figures are formed either by lines of dwarf-box, with intervening alleys and tracks of turf, sand, fine gravel, small shells, &c. or are formed sometimes entirely of verges of fine turf, disposed into wide or narrow compartments, as the figure may require; and sometimes they consist of box-edgings, and tracks of turf together: the partitions or beds of earth formed by the tracks of box and turf compartments, &c. are planted with some choice flowers; but no large plants to hide the figure of the Parterre; for the regularity of this in the artful distribution of the different figures, is intended as a decoration to the whole place long after the season of the flowers is past.

But many prefer a Parterre composed entirely of turf and beds of earth, perfectly even, without any other figure than the long square, forming a border of earth all round, within which is compartments of grass, and beds or borders of earth of different dimensions.

Sometimes Parterres, by means of box-edgings, are formed into labyrinths or mazes; and some are made to represent coats of arms with the proper supporters. All crowded designs, however, and such figures as are too much compound, are to be considered as so many labyrinths, in which the eye is lost, and therefore improper to be employed for any general plan.

Indeed Parterres in general are become in disrepute in England, their regularity being thought too stiff and formal, their figures often of a trifling appearance, and their making and keeping in proper order attended with considerable trouble and expence, so that they are almost banished the English gardens; substituting in their stead spacious grass lawns and rural shrubberies.

However, a little Parterre-work for the sake of variety, might still be admitted, though not immediately in the front of the house, as heretofore in ancient gardening. A spacious lawn, bounded with a rural shrubbery,

bery, is the most eligible for that situation; but a plain Parterre of a moderate extent, either formed with lines of box, or with turf, might be introduced in some of the more internal parts, and distributed into plain compartments, or beds of earth for flowers, so as to answer the purpose of a flower-garden for the most curious sorts; it will have an agreeable effect in forming a contrast to the more rural scenes.

PARTING ROOTS, an expeditious mode of propagation, for the increase of great numbers of fibrous-rooted perennials in particular.

Great numbers of the herbaceous fibrous and tuberous-rooted perennial tribe often increase by the root into large clusters or bunches, composed of numerous small slips or off-sets particularly many of our flowery perennials, illustrated in campanula, perennial sun-flower, golden-rod, perennial asters, polianthus, and daisy, with innumerable other sorts; which from one small slip or off-set of the root often multiply in a season or two into a large cluster of such off-sets, and these clusters of roots being parted into several separate slips, with root-fibres at their bottom, and a bud at top, each commences a distinct plant; so that by thus Parting the Roots you may instantly multiply one plant into many, each of which becomes alike in growth and general habit to the original, and will all flower the ensuing season in their due course; and in their turns detach from their sides all around, a due supply of off-sets for farther propagation.

The sorts of plants that are usually increased by this mode of propagation are always exhibited in their respective genera under the head *Propagation*, &c.

The best general season for Parting Roots is in autumn, after they have done flowering, and their stalks decay, which is done in September and October, and the detached off-sets being planted directly, they will take good root before winter; though in many hardy sorts, Parting the Roots may be performed almost any time, in open weather, from September till March; and some of the tender kinds succeed best in spring: observing, however, in Parting Roots in the spring-season, it should be done before they begin to shoot forth their stalks, &c.

With respect to the method of Parting Roots, there is nothing more easy: when any plant you design to encrease, has multiplied

by its roots into a cluster of off-sets, the whole may either be taken up entirely, and the root parted into as many slips as are furnished with fibres, &c. or, on particular occasions, a quantity of slips may be detached from the sides all around as it stands in the ground: in either method, the work of Parting or slipping the Roots may in many sorts be effected easily with the hand; and in many others the assistance of a knife, &c. is often necessary in separating them properly; observing that when you want to make as great an increase as possible, you may part the root into as many slips as may be convenient, provided each is furnished with some fibre or root-part, and crowned with one or more buds or eyes for forming shoots at top; but when the detached off-sets are wanted for flowering as strong as possible the ensuing season, they should not be parted very small, but into middling-sized slips, where practicable, which being planted in the proper places will flower in tolerable perfection the following season.

The slips should generally be planted directly by dibble; the very small slips plant in nursery-beds to stand till next autumn, to acquire strength; then may be transplanted with balls into the places where they are to remain; and the larger slips, may be planted as soon as parted, at once where they are to continue.

This method of propagation may, if thought necessary, be practised to many sorts annually, as numbers of the herbaceous perennials multiply in one season into large bunches, as aforesaid, so as they may be encreased at pleasure in great quantities.

PASSERINA, Sparrow-wort.

The plants of this genus are shrubby exotic ever-greens of Africa, &c. for the greenhouse collection, rising with woody, downy, white, durable stalks, from about half a yard to six or eight feet high; garnished with small fleshy leaves; and small monopetalous, tubular, four-parted flowers.

Class and order, *Ostendria Monogynia*.

Characters.] **CALIX**, none. **COROLLA**, is monopetalous, with a slender tube, swelling below, and divided above into four spreading parts. **STAMINA**, eight bristly filaments placed on the tube, and nearly oval erect anthers. **PISTILLUM**, an oval germen, slender style, and capitated hispid stigma. **PERICARPIMUM**, is oval, leathery, and unilocular, inclosing one oval, pointed seed.

¹PASSERINA *Filiformis*.

Filiforme-leaved Passerina.] Hath a shrubby stem, branching laterally five or six feet high, covered with a white mealy down; filiforme, or very narrow convex leaves, closely imbricated four ways, and at the top of the shoots small white flowers.

This is the principal sort in the English gardens; it is a pretty ever-green, appearing beautiful at all seasons of the year.

²PASSERINA *Hirsuta*.

Hirsuted, or Hairy Passerina.] Hath a shrubby stalk, branching diffusely six or seven feet high, covered with a soft mealy down; thick, short, fleshy, imbricated leaves, smooth without, and downy within, and small white flowers.

³PASSERINA *Ciliata*.

Ciliated Passerina.] Hath a shrubby stalk, branching laterally five or six feet high, the branches naked below; but garnished at top with spear-shaped, erect, ciliated leaves, and small white flowers.

⁴PASSERINA *Uniflora*.

Uniflorous Passerina.] Hath a low shrubby stalk, branching out low into many smooth spreading branches, a foot and a half high; very narrow leaves placed opposite; and purple flowers singly at the termination of the branches.

These exotics flower here in June and July: the flowers are small, and not very conspicuous, and are rarely succeeded by seeds in England.

The plants in this country must be always kept in pots of good earth, and placed in the green-house collection, in order for having shelter in winter, managing them like myrtles and others of the hardier green-house shrubs.

The propagation of all the sorts is performed by layers and cuttings in spring or summer, giving frequent waterings, and occasional shade every day to the cuttings till rooted; and by the end of September both layers and cuttings will be fit to pot off separately.

PASSIFLORA, Passion-flower.

This genus of plants consists of celebrated shrubby and herbaceous floriferous climbers for the pleasure-garden, green-house, and stove; rising mostly with long, slender, cirrhone-climbing stems, ascending by tendrils many feet high; ornamented some with palmated many-lobed leaves, others are bilobed,

trilobed, multilobed, &c. and some with entire leaves; and at the axillas large pentapetalous nectariferous, spreading flowers, of singularly curious structure and beauty.

Class and order, *Gynandria Pentandria*.

Characters.] CALIX, is five-lobed, plane and coloured. COROLLA, five large half-spear-shaped, plane, obtuse petals, the size and figure of the calix, and a nectarium within the petals, formed of many fibres or rays, in a sort of triple coronet round the style, the exterior ones longest, and the upper ones drawing in narrow above. STAMINA, five awl-shaped gynandrous filaments, they being attached to a sort of pillar crowned by the germen, and are placed at its base, spread out every way, and terminated by oblong incumbent antheræ. PISTILLUM, a roundish germen elevated upon an erect pillar or column, and the germen supporting three spreading styles, crowned each with a capitated stigma. PERICARPIUM, an oval, fleshy, baccaceous, unilocular fruit, placed on a pedicle, and many oval seeds.

There are near thirty different species, but scarce one third of that number common to the English gardens; all of which are natives of foreign warm countries, in different parts of the world; and only one of them is hardy enough to succeed well here in the open ground; the others requiring shelter of a green-house and stove, but mostly of the latter.

Hardy Kind for the full Ground.

There is only one hardy species, a shrubby exotic from the the Brazils, which will prosper here in the full ground, planted against a warm south wall, where it will produce flowers and fruit annually; the flowers have singular beauty, but the fruit is only for variety as it grows, and for its seed for propagation.

¹PASSIFLORA *Cærulea*.

Blue-rayed Common Palmated Passion-flower.] Hath long, slender, shrubby, cirrhone-climbing, purpleish-green stalks, branchy and ascending upon support by their clasps thirty or forty-feet high; having at each joint one large palmated leaf, of five long folioles expanding like an open hand, accompanied at the same joint by a long twining cirrhi, or clasper; and at the axillas large spreading flowers, with whitish-green petals, and a blue radiated nectarium; succeeded by a large, oval, yellowish fruit.

It flowers from July until October; the flowers are very large, conspicuous, and their composition is exceedingly curious and beautiful.

The general structure of the singular flowers of this plant is, they come out at the axillas on pedunculi about three inches long, which they terminate, each flower having just close under the calix a three-lobed involucre-like appendage; a five-lobed calix, and a five-petalous corolla, the size, figure, and colour of the calix, &c. the petals arranging alternately with the calicinal lobes, the whole, including the involucre, calix, and corolla, make just thirteen lobes and petals, all expanded flat; and within the corolla is the nectarium composed of a multitude of thread-like fibres, of a blue and purple colour, disposed in circular rays round the column of the fructification, the outer ray is the longest, flat and spreading on the petals; the inner is short, erect, and narrows towards the centre; in the middle is an erect cylindric club-shaped column, or pillar, crowned with the roundish germen, having at its base five horizontal spreading filaments, crowned with incumbent yellow antheræ, that move about every way; and from the side of the germen arises three slender spreading styles, terminated by headed stigmas; the germen afterwards gradually becomes a large oval fleshy fruit, ripening to a yellowish colour.

These wonderful flowers are only of one days duration, generally opening about eleven or twelve o'clock, and frequently in hot sunny weather burst open with elasticity, and continue fully expanded all that day, and the next they gradually close, assuming a decayed-like appearance, and never open any more; the evening puts a period to their existence, but are succeeded by new ones daily on the same plant.

This plant and flowers are held in great veneration in some foreign catholic countries, where the religious make the leaves, tendrils, and different parts of the flower to represent the instruments of our blessed Saviour's passion; hence the name *Passiflora*.

Green-house Kinds.

There are two herbaceous species, exotics of Virginia and other parts of America, that will prosper here in the open air, sometimes the year round in a warm situation; but are

always subject to injury from severe frost, therefore it is proper to keep them principally in pots, in order to move to shelter of a green-house in winter.

Both the sorts have abiding roots, but the stalks generally decay here in winter, and are renewed again in spring.

²*PASSIFLORA Incarnata.*

Incarnated, or Flesh-coloured Italian Passion-flower.] Hath a strong perennial root; slender, herbaceous, cirrhose-climbing stalks, rising upon support four or five feet high; leaves composed of three sawed lobes, each leaf attended by a twining tendril; and at the axillas long slender pedunculi, terminated each by one whitish flower, having a greenish calix, and a reddish, or purple radiated nectarium, surrounding the column of the fructification, which succeed to a large, round, fleshy fruit, ripening to a beautiful orange colour.

The flowers of this species are also very beautiful, though of short duration, opening in the morning, and night puts a period to their beauty; but are succeeded by a daily supply of new ones.

The fruit of this sort is also very ornamental, as ripening to a fine reddish orange colour; but these rarely attain perfection here, unless the plants are placed in the stove, therefore when there is such accommodation, it highly merits that indulgence, where it will exhibit both flowers and green and ripe fruit, all at the same time in a beautiful manner. Remarking, however, it will flower in the open air freely in summer, but not perfect its fruit, so as to appear so ornamental, as with the indulgence of a stove.

³*PASSIFLORA Lutea.*

Yellow Virginian Passion-flower.] Hath a creeping perennial root; weak, slender, herbaceous, cirrhose-climbing stalks, rising upon support, three or four feet high; heart-shaped, three-lobed, smooth leaves, having three equal, obtuse, entire lobes; each leaf attended by a twining clasper; and shortish pedunculi sustaining small yellowish flowers.

Some of both these species should always be retained in pots for removing them under shelter of a green-house or garden-frame in winter, to have protection from frost; and some may be planted in a dry warm situation against a south wall, where they will live thro' our moderate winters, but are liable to suffer in severe frosts, unless they are covered.

Stove

Stove Kinds.

The *Passifloras* of this temperature are exotics of South America and other hot parts of the world, and require the shelter of a stove here, and of which the following are the principal sorts in our garden; some of them have undivided leaves, others are bilobate, and trilobate, &c.

¹*PASSIFLORA Serratifolia.*

Sawed-leaved Surinam Passion-flower.] Hath slender, angular stalks, climbing by the tendrils several feet high; undivided, oblong-lanceolate leaves, serrated on the edges, accompanied by twining cirrhi; and axillary reddish-green flowers.

²*PASSIFLORA Laurifolia.*

Laurus-leaved Passion-flower.] Hath long, tough, rough, branchy, cirrhone-climbing stalks, rising by support twenty or thirty feet high; undivided, oval, thick, entire leaves, on biglandulous foot-stalks; and axillary snowy white flowers, striped or spotted with red, blue, and yellow, and with violet-coloured rays, a yellow column, purple styles, and indented involucre.

³*PASSIFLORA Vespertilio.*

Vespertilion-leaved, or Bat's-wing Passion-flower.] Hath slender, striated, branchy stalks; large, bilobate or two-lobed leaves, the base roundish and glandular, the lobes acute, widely divaricated like a bat's wings, and dotted underneath; and axillary flowers, having white petals and rays.

The leaves of this species have a singular appearance, the two lobes being expanded six or seven inches wide, resembling the wings of a bat upon flight; hence the name *Vespertilio*.

⁴*PASSIFLORA Rubra.*

Red Passion-flower.] Hath roundish or angular stalks; bilobate, heart-shaped acuminate leaves; and red flowers, succeeded by an hexagonal scarlet fruit.

⁵*PASSIFLORA Maliformis.*

Apple-fruited Passion-flower.] Hath long, thick, triangular, cirrhone-climbing stems, rising by support fifteen or twenty feet high; undivided, large, oblong-heart-shaped, entire leaves, on biglandular or two-eared foot-stalks; and long axillary peduncles, sustaining large, white-petalous flowers, having reddish entire involucre, and purplish rays, succeeded by large maliforme, or apple-shaped yellow fruit.

⁶*PASSIFLORA Holoferrea.*

Silky-leaved Passion-flower.] Hath long, slender, downy stalks, climbing by support twenty feet high; three-lobed halbert-shaped, downy, soft, silky leaves; having each side of the base indented and reflexed; and axillary white flowers, with purple and yellow rays.

⁷*PASSIFLORA Multiflora.*

Multiflorous, Passion flower.] Hath long, slender, cirrhone-climbing stalks, rising by support twenty feet high; undivided, oblong, entire leaves; and flowers growing in clusters, having white petals and purple rays; succeeded by smallish, egg-shaped, yellow fruit.

⁸*PASSIFLORA Quadrangularis.*

Quadrangular-stalked Passion-flower.] Hath long, four-cornered, membranous stalks, climbing many feet high; undivided, almost heart-shaped entire leaves, on foot-stalks having six glands; and large white and purple flowers.

⁹*PASSIFLORA Suberosa.*

Cork-barked Passion-flower.] Hath slender stalks, climbing fifteen or twenty feet high, having a whitish, fungus, cracked bark, like the cork-tree; three-lobed, target-shaped leaves; and small whitish-green flowers.

All these species of *Passiflora* flower here in summer, beginning commonly in July, and continue in succession for two or three months; for although the flowers of all the sorts are scarcely of more than one day's duration, they are succeeded by new ones daily, for as the shoots advance, fresh flowers arise at the joints; in all the sorts they consist each of a five-lobed calix, and a corolla of five petals, and circular rays in the centre, surrounding the column of the fructification (see the *Characters*); and many of the sorts are succeeded by fruit in our gardens, which in all the sorts is of an oval form, some of the size of large plums and middling apples, and some not larger than gooseberries.

All the twelve species here enumerated, are of the cirrhone-climbing kind, i. e. climbing by means of their twining *cirrhi*, or *claspers*, that catch hold of any adjacent support. See CLIMBING PLANTS.

As all the species are natives of warm countries, in these parts they are mostly of a tender quality, except the first sort, which succeeds very well in the full ground, in a warm

situation ; only their young branches are sometimes killed in very severe winters ; but plenty of new ones generally rise again in spring following : the second and third sorts, however, are tender, and must, for the most part, have shelter in winter : all the others, denominated stove kinds, must always be retained in that repository.

The first species, *Passiflora Cærulea*, being the hardiest, is considerably the most common sort in our gardens ; is superior both as a climber, and in the beauty of its flowers : as a climber it demands our particular notice, for it may be trained to the top of the highest walls, even if thirty or forty feet high, and will often shoot fifteen or twenty feet in one season ; producing from the joints as they advance, a plentiful succession of their extraordinary flowers for three months ; therefore this fine climber highly merits a place in every garden ; and may be easily raised from seed, layers, and cuttings (see its *Propagation*) ; or may be purchased reasonable at all the nurseries. The season for transplanting it is early in autumn, or in February or March.

It should generally be planted against some high warm wall, in order for training its branches, for they must be supported, otherwise they will trail on the ground, or entangle with one another, so that its stems and branches must be constantly nailed up to the wall five or six inches asunder ; and according as they shoot during summer, train in most of the shoots for flowering, and principally at full length for the present, suffering them to remain so all the winter ; and in spring the whole may be pruned, cutting out all dead shoots that have been killed by the frost, and where the branches or shoots are too much crowded, thin out all the weakest and worst placed ; leaving a due supply of the strongest shoots at proper distances in every part from bottom to top, and let each of those be shortened to about a yard, or four or five feet long, according to their strength, both to confine them within proper compass, if necessary, and promote their throwing out strong shoots for the ensuing summer's bloom, for the flowers are produced always upon the shoots of the year.

As in severe winters their branches, if not protected, are sometimes killed, it is advisable at such times, whilst the plants are young in particular, to grant them shelter of mats during the inclement season, and protect their roots with dry litter laid over the ground :

observing, however, to uncover their branches as soon as the frost breaks : this covering, however, is only necessary in very severe frosts.

The two green-house sorts should generally be potted, to move to shelter in winter, either of a green-house or garden-frame : some plants of each sort may also be planted in the full ground, in a warm border, to take their chance ; observing to cover the ground over their roots in severe weather ; observing in both methods to place stakes in summer to train the stems and branches upon.

All the stove kinds must constantly be kept in pots, placed always in the stove, and for the most part plunged in the bark-bed ; placing strong stakes for the purpose of training the branches ; managing them as other stove-plants of a similar nature. See STOVE-PLANTS.

Propagation, of all the Sorts.

The propagation of all these species of *Passiflora* is, by seed, by layers, and by cuttings ; under the following heads, hardy kind, green-house kinds, and stove kinds.

Hardy Kind.—This sort, common Passion-flower, is raised in the three following ways. First, by seed : in March sow the seed in large pots, half an inch deep, and either plunge them in a warm border, and as the weather becomes warm move them to the shade ; or if as soon as the seed is sowed, the pots are plunged in a hot-bed, it will forward the germination of the seed, and the plants will rise sooner ; which harden gradually to the open air till october ; then place them under a garden-frame for the winter, to have shelter from frosts, and in spring plant them out in nursery-rows, and in a year or two they may be transplanted where they are to remain, against some warm south wall. 2. By layers : in spring lay down some of the branches in the common way, they will readily emit roots, and make proper plants by autumn ; when, or rather in spring following, transplant them either in nursery rows, or where they are to remain. 3. By cuttings : in February or March cut off a quantity of strong young shoots, in length of from about eight to ten or twelve inches, plant them in any bed or border of common earth, giving frequent watering in dry weather, and when sunny and hot, a moderate shade of mats will be of much advantage, and they will emit roots at bottom, and shoots at top, and become good plants by autumn, allow-

allowing them occasional shelter of mats, &c. during the winter's frost, and in spring plant them out.

If a quantity of these cuttings are planted close, and covered down with hand-glasses, it will forward their rooting; observing, however, when they begin to shoot at top, to remove the glasses.

Green-house Kinds.—Both the sorts, by seeds, layers, and parting the roots. 1. By seed. This is commonly obtained from America; sow it in pots in March, and plunge them in a hot-bed to raise the plants, which inure to the open air in summer, and give them shelter of a green-house or frame in winter, and in spring plant some out in pots, and place them among the green-house and other plants in the full ground, under a warm fence to take their chance. 2. By layers. In spring lay some young shoots; they will readily grow and become good plants for potting off in autumn. 3. By parting the roots. In spring, before they begin to shoot, is the proper time; the second sort in particular multiplies exceedingly by its creeping roots; which divide into slips, and plant them in a bed of rich earth till autumn, when some should be transplanted into pots for occasional shelter in winter.

Stove Kinds.—All these sorts by seed, layers, and cuttings.

By Seed.—This is procured chiefly from abroad; sow it in spring in pots, plunge them in a hot bed, or in a stove bark-bed; the plants will soon appear, which, when three inches high, prick out in separate small pots, give water and plunge them again in the hot-bed, giving occasional shade till rooted; as they advance in growth shift them into larger pots, and retain them constantly in the stove.

By Layers.—In spring, or beginning of summer, lay the young branches, they will readily grow, and be fit to pot off separately in autumn.

By Cuttings.—In spring or summer plant some cuttings of the young shoots in pots, plunge them in the bark-bed, give water frequently; most of them will take root, and be fit to pot off singly in autumn.

PASTINACA, Parsnep.

The principal of this genus is that well known herbaceous esculent, *Garden Parsnep*, a biennial of high estimation for its large eatable root, valuable for winter and spring ser-

vice, crowned with large pinnated leaves, and umbelliferous flowers.

Class and order, *Pentandria Digynia*.

Characters.] CALIX, multiple umbelliferous flowers, destitute of an involucre, and with scarcely visible cups to the florets. COROLLA, a uniform umbel of many small florets, composed each of five spear-shaped involute petals. STAMINA, five hair-like filaments, and roundish antheræ. PISTILLUM, a small germen under each floret, two reflexed styles, and obtuse stigmas. PERICARPIUM, none, a plane compressed elliptical, two-parted fruit, having two elliptic seeds, surrounded with a border.

There are only two species of this genus, the principal of which for our purpose is the common parsnep, viz.

PASTINACA *Sativa*.

Cultivated, or Garden Parsnep.] Hath a large, long, fleshy root, penetrating perpendicularly into the ground, half a yard or two feet in length, three or four inches or more thick at top, tapering gradually to the lower end; crowned with very large singly-pinnated leaves; and when it shoots for seed, rises with an upright, strong, channelled, hairy stalk, branching four or five feet high, having all the branches terminated by large yellow umbels of flowers.

Variety.] Wild Parsnep with hairy leaves.

They are biennial plants, that being raised from seed in spring, shoot up only leaves the first summer, and the roots attain perfection for use the succeeding autumn and winter; and in the spring after they shoot up into stalk for flower and seed, and having ripened seed, totally perish; so that a fresh supply must be raised annually.

The Garden Parsnep is an exceeding fine esculent root, though by reason of its peculiar sweet relish, it is not in general estimation; it, however, is a very wholesome and nourishing root, to many very palatable, and is very profitable for family service, and goes off well in the markets.

The principal season of parsneps is from October or November until March; for they are seldom good till they have attained their full growth, determinable by their leaves beginning to turn yellow and decay in autumn; and they will continue in great perfection until March or April, that they begin to shoot up into stalk for seed, when they become hard, sticky, and unfit for eating.

Its Propagation and Culture.

The propagation of this esculent root is by seed annually in the open quarters of the kitchen garden. February and March is the proper season for sowing. Observing to procure fresh seed, for if more than one year old, it will not grow.

I should advise the main crop of Parsneps to be sowed alone, and not mixed with other crops, such as onions, leeks, or carrots, as often practised, for there is nothing gained by this, it rather causes confusion, and more trouble in the culture; but by sowing them separate, their culture can be more regularly attended to, and the crop will attain greater perfection.

Chuse for this crop a spot of light, rich, deep soil, in one of the most open airy quarters, which should be trenched one full spade deep at least, or if two the better, provided the depth of good staple admit, that the roots may have a due depth of loose soil to run down to their full length: observing, that if the ground is previously trenched up in rough ridges in winter, especially if any ways stiff or wet, and let it lie exposed some time to the sun and air, it will improve its temperament greatly for this purpose; then at sowing time level it down, in dry weather, for the reception of the seed, breaking all large clods, and leave an even surface, but not rake it till after the seed is sowed, which should generally be performed whilst the ground is fresh stirred, or at least before the surface becomes too dry, so as in raking the clods will readily fall under the rake to bury the seed regularly.

Sow the seed by broad-cast thinly, either all over the surface, or the ground may be divided into four-feet wide beds, as shall be convenient, though for large quantities the former is the most eligible practice; as soon as the sowing is done, tread down the seeds evenly, and finish with an even raking, to cover all the seeds equally, and to smooth the surface: in about three weeks, or a little more or less time, the seeds will germinate, and the plants will appear above ground, when they should be thinned and weeded as directed below.

When the plants are two or three inches high, proceed to thin them to regular distances, and clean them from weeds; which works should generally be performed by a

three or four-inch hoe; chuse dry weather, and cut out the plants to about ten or twelve inches distance, for they should have large room, cutting up all weeds as you proceed; after this no more culture will be required till the future progress of the weeds render another hoeing necessary; and probably another repetition may also be required, till the plants are in full leaf, when they will cover the ground, and bid defiance to any farther interruption from weeds, and will not require any farther attention till autumn, when the roots will become fit for use.

In October the roots will be arrived nearly at full growth; when the leaves begin to turn yellow and decay, is a certain sign of maturity, and may then begin to dig up some of them for use, according as they are wanted.

These roots may either remain in the ground all winter, and be taken up according as they are wanted; or may be dug up in November, and their tops pared off close, then buried all winter in sand, in some shed or other dry place, to be ready at all times for use, as directed for carrots, which may be practicable enough for small quantities: you may leave some, however, in the ground for spring service, till January or the beginning of February, just before they begin to shoot, then dig them up and lay them in sand; and by taking them up at this time, it will retard their effort for shooting, so as they will continue in tolerable perfection until the latter end of April.

Parsneps when raised for sale generally make a tolerably profitable crop, particularly about London, where they are always ready sale, from November till April. In preparing them for market, they pare off the top quite close, and trim the lower end, and wash them clean; then bunch them up with osier rods, in flat bunches, six or more roots in each, according to their size: thus prepared they are sold in market to the retailers at from two or three to four or five shillings per dozen of bunches.

Saving Seeds of this Plant.

To have parsneps always in due perfection, great care is necessary to save seed only from some of the finest roots.

Therefore in autumn or November select a quantity of the large, long, straight roots, trim off their leaves, and plant them in rows three feet asunder, two distant in the lines, and about an inch deep over their top; thus,

P E D

thus they will shoot up strong in spring for flowering, and will ripen seed in the latter end of August, or early in September; when in dry days cut off the umbels of seed, and spread them upon mats to dry and harden, then thrash out the seeds, and put them up in bags for sowing next spring.

PEDICELLUS, Pedicle, a partial flower-stalk, or proper stalk of any single flower of an aggregate or cluster of flowers; the main flower-stalk which proceeds immediately from the plant, and supports one, two or many flowers, is termed the *Pedunculus*, or common foot-stalk of the flowers; and all the lesser stalks detached from the sides or any part of this, are by Linnæus styled *Pedicellus*. See **PEDUNCULUS**.

PEDUNCULUS, Peduncle, the main foot-stalk of a flower, or head of flowers, bearing the fructification only, and not the leaves.

The Peduncle is often divided or branched into others, and each of the divisions is termed a *Pedicellus*, or little flower-stalk; so that the principal foot-stalk of any head or cluster of flowers, is styled the common flower-stalk or *Pedunculi*; each of the lesser foot-stalks issuing from it is the partial stalk, or pedicle, of any single flower in the aggregate, head, or cluster of flowers, supported by the main foot-stalk, or Peduncle; thus the *Pedicellus* is always distinguishable from the main flower-stalk, or *Pedunculus*. See **PEDICELLUS**.

The *Pedunculi*, or main flower-stalks, are also distinguished by different epithets, according to the place of the plant from which they proceed, as the root, stem, branch, axillas, termination, &c. viz.

Pedunculus radicalis, radical, or root flower-stalk, rising immediately from the root.

Pedunculus caulinus, cauline, or stem-flower-stalk; when it proceeds from the stem.

Pedunculus rameus, ramous, or branch-flower-stalk; when it proceeds from the branches.

Pedunculus axillaris, axillary, or bosom-flower-stalk; when it proceeds from the axilla, i. e. comes out at the angles between the leaf and stem, or branch, or between the branch and stem. See **AXILLA**.

Pedunculus terminalis, terminal-flower-stalk; when it proceeds from the termination or end of the stem or branch.

Pedunculus solitarius, solitary Peduncle; when it grows singly, or only one in the same place. Remarking that a solitary Peduncle may support many flowers; but a solita-

P E R

ry flower implies a single or solitary flower-stalk.

Pedunculi sparsis, sparfid, or scattered-flower-stalks; when they grow many together, scattered without any order.

Lastly, the Peduncle bears other different epithets, both from the number of flowers on each, and from the different modes in which the flowers are borne and connected on the Peduncle, &c.

To express the number of flowers on each Peduncle, they are called *uniflorous* when they bear but one flower; *biflorus* when two flowers; *triflorus*, when three flowers; and *multiflorous* when many flowers.

And to express the different principal modes of bearing the flowers, they are termed either *capitulum*, i. e. little head, or compact round cluster; *spica*, the spike; *corymbus*, a corymbous; *umbellata*, an umbel; *panicula*, the panicle; *thyrsus*, the thyrses; *racemus*, a cluster; *verticillus*, the verticilli, or whorled-spiked. See each under its respective head.

To the above modes of flowering may also be added: *aggregatus*, the aggregate; *amentaceus*, the amentum; and *spadiceus*, the spadix. See **AGGREGATUS**, **AMENTACEUS**, and **SPADICEUS**.

PENDULUS *Flos*, Pendulous flowers; such as hang downward in a loose dangling manner.

PENTANDRIA, the name of the fifth class; consisting of plants with hermaphrodite flowers, having five stamina, and comprises six orders derived from the number of styles. See **CLASSIS**.

PENTAPETALI, Pentapetalous, or five petals; flowers that have five petals. See **COROLLA**.

PERENNIS *Plantaris*, Perennial, or everlasting plants; plants that are perpetuated by the roots, that is, whether their leaves and stalks decay annually in winter, or always remain, provided the roots are of several years duration, they are still Perennial plants.

All plants, therefore, with abiding roots, both of the herbaceous tribe in general, and of the shrub and tree kinds are Perennials; though in the general acceptation of the word Perennial, it is most commonly applied to herbaceous vegetables with durable roots, more especially those of the flowery kind, which among gardeners are commonly called simply Perennials, particularly the fibrous-rooted tribe; but it is equally applicable to fibrous, tube-

tuberous, and bulbous-rooted plants, whose roots are of several years duration: likewise all shrubs and trees of every denomination, as having abiding roots, are also Perennial plants.

Perennial plants consist both of deciduous and ever-green kinds; those that cast their leaves, &c. in winter are termed deciduous Perennials, and those which retain their leaves ever-greens.

Of the herbaceous Perennials, however, both of the fibrous-rooted tribe, tuberous and bulbous-rooted kinds, far the greater part have annual stalks, rising in spring and decay in winter; and a great many lose their leaves entirely also in that season, such as the Perennial sun-flower, asters, and numerous other sorts; and many sorts retain their leaves all the year, but not their stalks, exemplified in the auricula, polyanthus, some *campanulas*, pinks, carnations, and many others.

Great numbers of the herbaceous Perennials multiply exceedingly by off-sets of the root, by which they are propagated in great abundance. See OFF-SETS and PARTING ROOTS.

All the tree and shrub Perennials are durable both in root, stem, and branch; but all renew their leaves annually, even the ever-green kinds, although they are in leaf the year round, yet they put forth new leaves every year, to which the old ones gradually give place.

PERIANTHIUM, flower-cup, or the most common species of calix, placed immediately under the corolla, containing it as in a cup. See CALIX.

Many flowers, however, are destitute of a *Perianthium*, or flower-cup, such as most of the liliaceous plants, as the lily, tulip, crown-imperial, &c.

But far the greater number of plants are furnished with a proper flower-cup, and is of different structures in different genera: for some explanation, see CALIX.

PERICARPIUM, the seed-vessel of plants, analogous to the fecundating ovary in animals; and is formed of the germen, or seed-bud in the centre of the flower; which when fertilized by the male-dust of the antheræ, it then, and not before, becomes a *Pericarpium*, pregnant with seed, and gradually swells to maturity, and the seed ripens accordingly. See GERME and SEMEN.

All plants, however, are not furnished with a *Pericarpium*; in default of which,

either the receptacle or calix performs that function, by inclosing the seeds and accompanying them to maturity.

A *Pericarpium* comprises different species or sorts of seed-vessels, as follows:

CAPSULA, capsule; a dry hollow seed-vessel, that naturally cleaves or separates in some determinate manner in one, two, three, or more valves, or openings, for dispersing the seeds; so have often from one or two to many valves, as well as loculi, or seed cells, as hereafter hinted. See also CAPSULA.

LEGUMEN, a legum or pod; a seed-vessel that has two valves or openings, inclosing a number of seeds fastened along one suture or seam only, such as the pea, bean, &c. See LEGUMEN.

SILIQUA, a seed-pod, with two valves, having the seeds attached alternately to both sutures, or joining of the valves, as in cabbage, turnep, wall-flower, stock-gilliflower, &c. See SILIQUA.

FOLLICULUS; having only one valve, opening from bottom to top, and having the seeds attached to a receptacle within.

DRUPA, a stone fruit, of a fleshy or pulpy nature, without any valve or external opening, and contains a stone or nut; the cherry, plum, peach, and most other stone fruit, are all Drupaceous seed-vessels.

BACCA, a berry; a pulpy fruit without a valve, inclosing a number of seeds; as in the currant, gooseberry, strawberry, &c. See BACCA.

POMUM, apple; a fleshy fruit of the apple-kind, without any valve or external opening; having in the middle a membranous capsule of several cells, containing the seeds. See POMUM.

STROBILUS, a scaly fruit of the cone-kind; being composed of a number of woody scales, exemplified in the cones of the *Pinus*, fir-tree, &c. See CONUS, and STROBILUS.

Each of the above species of *Pericarpium*, although of a peculiar structure, yet the same sort is often of different figures and magnitudes in different genera, as is expressed in their respective *Characters*; as oblong, oval, roundish, conical, and various other shapes; and some *Pericarpiums* having from one or two to many valves or openings, particularly the capsule-kind, which, when of one valve, is termed an *univalvular*, or one-valved *Pericarpium*; of two valves, *bivalvular*; of three, *trivalvular*; of four, *quadrivalvular*; of five, *quinque-*

quevalvular; of many valves, *multivalvular*. Likewise different *Pericarpiums* have from one or two to many *loculi*, cells or lodgments of the seeds; so that when of one *loculi* or cell, it is termed an *unilocular Pericarpium*; of two cells, *bilocular*; of three, *trilocular*; of four, *quadrilocular*; of five, *quinquelocular*; and of many cells, *multilocular*, &c. all of which is fully exhibited as they occur in discriminating the *Characters* of their respective genera, for the *Pericarpium* is always employed as an essential distinction in each genus; and is likewise often used as a descriptive mark in distinguishing the species in many genera.

With respect to the seeds, relative to their number, figure, size, &c. in the *Pericarpium*, it is very different in different genera; as in point of number, they are from one to many hundreds; and their figure and size are also exceedingly various, as is expressed in the *Characters* of each genera, &c. See also SEMEN.

PERIPLOCA, Climbing Dog's-bane, or Virginian Silk.

It consists of ligneous, volubilate-climbing exotics for the shrubbery, green-house, and stove, rising with twining stalks about any support many feet high; garnished with oval-oblong and heart-shaped entire leaves, and monopetalous wheel-shaped, five-parted flowers in clusters.

Class and order, *Pentandria Digynia*.

Characters.] **CALIX**, is five-parted and permanent. **COROLLA**, is a monopetalous, rotated, plane, and divided into five narrow segments, and with a very small nectarium furrounding the centre of the corolla. **STAMINA**, five short incurved filaments, and erect antheræ. **PISTILLUM**, a bifid germen, two cylindric styles, and headed stigmas. **PERICARPIUM**, two large, oblong, ventricose, unilocular follicles, filled with numerous imbricated seeds crowned with down.

There are but three or four species, all exotics from distant countries, of which one is hardy for the shrubbery, one for the green-house, and the other for the stove.

¹**PERIPLOCA Græca**.

Grecian Periploca, or Common Climbing Dog's-bane.] Hath shrubby, long, volubilate-climbing, branchy stalks, winding round any support thirty or forty feet high; large, oblong-spear-shaped leaves, opposite by pairs, of a shining-green above, and whitish underneath; and

at the axillas towards the ends of the shoots small clusters of purple flowers, hairy within.

²**PERIPLOCA Africana**.

African Hairy-stalked Periploca.] Hath ligneous twining, hairy stalks, rising upon support near three feet high; oval hairy leaves, by opposite pairs; and from the sides of the branches small clusters of purpleish flowers.

Varieties.] Smooth-stalked African *Periploca*—sinuated-leaved.

³**PERIPLOCA Indica**.

Indian Periploca.] Hath shrubby, slender, volubilate-climbing stalks, rising by support several feet high; oval-spear-shaped, smooth leaves; and flowers in imbricated spikes of different colours in the varieties.

These three plants flower principally in July and August, generally in small bunches; each separate flower is of one plane petal, cut into five segments; but are rarely succeeded by seeds in England.

These plants are retained in many of our gardens, to add to the variety of climbers.

The first sort in particular is a fine volubilate-climbing plant for the shrubbery. It will readily wind its stalks and branches round any adjacent tree, hedge, pole, or any thing it encounters in its progress, and rise to a prodigious height; and in default of any neighbouring support it will twine and entangle its branches round one another in a complicated manner; but it should generally be allowed support, and it will shew itself to much greater advantage.

The second and third species should always be kept in pots, placing the former among the green-house exotics to have shelter in winter; and the latter placed always in the stove.

The propagation of all the sorts is easily effected by layers, which if layed in the spring, or early in summer, they will be rooted sufficiently by autumn, and may then be transplanted; the hardy kind into the nursery, the others in pots.

Cuttings of the first sort will also often succeed; likewise of the other two, by aid of a hot-bed.

They may also all be raised from seed procured from abroad; which should be sowed in spring in pots, and plunged in a hot-bed, especially of the second and third sorts.

PETALUM, Petal, the fine coloured leaves of the flower, which form the *Corolla*. See **COROLLA**.

PETI-

PETIOLUS, the foot-stalk of the leaves only, very different from the *Pedunculus*, the foot-stalk of the flowers; for it is in very few instances that either the same *Petiolus*, or *Pedunculus*, support both leaves and flowers; Linnæus, therefore, has very properly marked their distinction by assigning each a different name.

The *Petiolus*, or foot-stalk of the leaves, is very commonly furnished with two distinct surfaces, a front and a back; the former flat, the latter round.

Some leaves, however, have no foot-stalks at all, but are close-fitting, or *sessile*. See **FOLIUM**.

PHASEOLUS, Kidney-bean.

This noted genus consists principally of herbaceous annuals; one species of which, *common Kidney-bean*, is the chief, and is a most valuable leguminous vegetable, comprising many excellent varieties, both dwarf-growers and high-climbers; garnished universally with trifoliate leaves, and papilionaceous hermaphrodite flowers, succeeded by long leguminous seed-pods, which, whilst young and tender are fine culinary esculents, and the principal eatable part of the plant; also sometimes the ripe seed or beans contained in them.

Class and Order, *Diadelphia Decandria*.

Characters.] **CALIX**, is monophyllous, and two-lipped, the upper one emarginated, and the under tridentate. **COROLLA**, is papilionaceous, with a heart-shaped vexillum, reflexed on the sides, oval wings as long as the vexillum, and a narrow keel, twisted contrary to the sun's motion. **STAMINA**, ten diadelphous filaments, and single antheræ. **PISTILLUM**, an oblong, compressed, hairy germen; a filiforme, inflexed, spiral, downy style, and obtuse hairy stigma. **PERICARPIUM**, a long, thick, coriaceous, pointed pod, containing kidney-shaped compressed seeds.

There is only one species of Kidney-bean proper for general culture, but it is very profuse in varieties, and is the parent species of all those noted kinds, known in our gardens, both dwarf-growers and climbers.

The species is:

PHASEOLUS *Vulgaris*.

Common Kidney-bean.] Consisting of the following principal varieties in two classes—dwarf-growers—and high-climbers, or runners.

Dwarf Kinds.

Dwarf Kinds, their general description is:—

The plants rise each with an upright short stem, branching out low into a bushy head, from about ten or twelve inches to a foot and a half high, rarely sending out runners; garnished with trifoliate leaves, and clusters of white or purple flowers, in different varieties, succeeded by long, narrow, hanging seed-pods.

Principal Varieties are:] Small, early, white dwarf Kidney-bean—small early yellow—early liver-coloured dwarf—early black or negro dwarf—larger white, or cream coloured dwarf—larger black and white speckled dwarf, a good bearer—black-streaked dwarf—speckled amber dwarf—sparrow-egg dwarf—Canterbury white dwarf, a great bearer—Battersea white dwarf, also a very great bearer. All of which kinds are of upright dwarf bushy growth, rarely exceeding fifteen or eighteen inches height; and seldom throw out runners, except the two latter sorts, which sometimes emit a few stragglers, but they seldom ramble far.

Observe that with respect to the above-mentioned colours of the varieties, it alludes to that of the beans or seed, which also often vary to several other intermediate colours and variegations.

Of the above varieties of dwarf Kidney-beans, the first three or four sorts are at present in esteem for their coming earliest into bearing; they being of smaller growth than the other sorts, and sooner form themselves for blossom and bearing, so are proper to plant for the earliest crops, and for forcing in hot-beds, &c. As they, however, do not continue long in bearing, they are not so proper for the main crops, as the other larger dwarf sorts; particularly the black and white speckled, the Canterbury and Battersea kinds, which are all excellent bearers; but the two latter most of all, and the pods are smaller, more numerous, and esteemed the sweetest eating of all the dwarf kinds whilst young, though the pods of the large white dwarf, and the speckled kind in particular, continue tolerably good, even when of a pretty large size; but in the Battersea and Canterbury sorts they are soon apt to become tough and stringy: these two sorts, however, are in most esteem for general culture by the market-gardeners in the neighbourhood of London, for the main crops, as being by them considered both

as the most profitable in bearing, and being a smaller pod, the most saleable in the markets.

As all these dwarf Kidney-beans are of upright growth, without emitting any very rambling runners, they do not require support, like the climbing kinds; so may be cultivated in drills not more than two or three feet asunder. See their *Propagation and Culture*.

Climbing Kinds, or Runners.

Climbing Kinds, their general description is:— The plants rise with a short stalk; emitting several long, slender, twining runners, winding round any support, many feet high; garnished with large trifoliate leaves; and at all the joints, as the runners advance, large clusters of scarlet or white flowers in different varieties.

Of the climbing sort are the following principal varieties.

Large scarlet climber, — Rises with many twining runners upon support, twelve or fifteen feet high, having numerous large clusters of scarlet flowers; succeeded by large, thick, rough seed-pods, containing large, thick, purpleish beans.

Variety of this] Large white climber, having large clusters of white flowers, large, thick, rough seed-pods, and white seed.

Both these sorts are alike in every respect of growth, and only differ in colour of their flowers and seed, as above; which is pretty permanent: they are both extraordinary great bearers; and the plants of the same crop continue in bearing from July or August until October; and the pods of both sorts, even when large, boil exceedingly green, and are remarkably tender and well flavoured.

Large Dutch Climber, — Rises with twining runners, upon support, ten or twelve feet high; numerous clusters of white flowers; succeeded by long, flat, smooth pods, containing large, oblong, flat, white seed.

This variety is also a very great bearer, but it does not continue so long in bearing as the two former climbers; and the pods, though very good eating, are rather inferior to those of the scarlet kind, and its variety; it is nevertheless a very good family bean.

The following climbers are of more moderate growth.

Negro runners—Battersea white runners—Canterbury runners—variable runners. All of which, though climbers, do not ramble

far, and bear plentifully, but not continue so long as the above-mentioned climbers; the pods are smaller, but are excellent eating while young.

Thus far concludes all the principal varieties of the *PHASEOLUS Vulgaris*, or common Kidney-bean, that have merit for general culture.

In the different varieties, both of the dwarfs and climbers, the shape and size of the seed-pods, and seed vary a little, that is, the pods are generally long and narrow, i. e. from about three or four to six or seven inches long, and from about a quarter of an inch to an inch broad, and mostly compressed, but in some are more flattened, and thinner than others, and some incline a little to a cylindric form, and of thicker substance; those of some of the climbers are much larger than the dwarf; observing in general that as the young green seed-pod are, in this country, the principal edible part of the plant, those of the thickest fleshy texture that break crisp and tender, are generally preferable. And as to the seed, it is most commonly Kidney-shaped, though some incline a little to an oval form, and some roundish: in some varieties it is very small, some middling, and some large; and according to the size of the seed, the plants of the respective varieties are generally smaller or larger in proportion. The ripe seed in some countries is also preserved for eating in winter; but the most estimable part for use in England, is the young pods, as aforesaid, whilst they are green and tender, before the seed in them acquires any considerable size; they are thus boiled and eaten as sauce to flesh meat. The quite young pods are also in great estimation for pickling, and make a very delicate pickle for use all the year: the young pods are also often salted down in barrels, or earthen vessels, for winter use, in which they will keep exceedingly fine several months. The ripe seed also, as above hinted, of the white kinds, is sometimes boiled for eating, particularly in France and some other parts on the continent, where they are constantly preserved for winter use, as we do dried peas; which they stew and make very palatable with butter, gravy, and other sauces.

All the varieties of this species, both dwarfs and climbers, are originally exotic annuals from the hot parts of the world; and in this country are rather of a delicate temperature,

ture, impatient of cold, and not able to bear the open air here only in summer; they being raised from seed in April, May, and June; and the first autumnal cold, in October or beginning of November, puts a period to their existence.

General Observations on their Culture.

As Kidney-beans are universally of the annual tribe, a fresh supply must be raised every year from seed; and as the plants of the dwarf kinds rarely continue in bearing longer than three weeks, several different plantings or sowings is necessary from April until July; but some of the climbing sorts will continue bearing two or three months. Observing of all the sorts, that, as being exotics of a tender nature, they will not succeed here in the full ground till April or May: the former of which is the earliest time for putting in the first crop, which will come into blossom in June, and by the latter end of that month will be succeeded by young pods fit to gather for use; and by different sowings may continue a succession of crops, bearing from June until October; but by aid of hot-beds may have the dwarf sorts very early in the year; and with the accommodation of a hot-house, you may have them at almost any time in winter or spring, in very great perfection.

The dwarf sorts are proper for the early and general summer crops; and for the supply of markets in particular, where large quantities are required, they are the only proper sorts for general culture, both because they require much less room to grow, and less trouble in their culture than the climbers, as not requiring to be staked; and the produce is generally more saleable, though not better for eating, only are to many persons more agreeable to the eye. To have a constant supply of these sorts in the natural ground from the earliest to the latest period, three or four different sowings, at least, are necessary from the beginning or middle of April until the latter end of July; and to have them as early as possible, some should be sowed in hot-beds in February and March; or in a hot-house they may be planted in the beginning or middle of winter, even to have beans at Christmas, and continued, in succession till those in the common hot beds, or in the natural ground come into bearing.

The climbing kinds are, for the most part, wonderful great bearers, particularly the scar-

let sort, and its white variety, which in the same crop often continue bearing plentifully from July until killed by the frost or cold in October; but all the climbers continue in bearing much longer than the dwarfs, for as their runners continue branching and shooting in length two or three months, they, according as they advance, continue sending forth large clusters of blossoms, succeeded by a proportional quantity of fruit: none of the climbers, however, are adapted for early crops, but succeed remarkably for the main crop, to supply the table from about the middle or latter end of July until October, especially in private gardens, where only moderate quantities are required, and have convenience of sticks to place for their runners to climb upon, for without such assistance they would trail on the ground, and entangle with one another in a confused manner, and be liable to rot, without affording a quarter of a crop: they should therefore all have sticks for support, and they will bear amazing great crops. But in the public kitchen-grounds, where considerable quantities of Kidney-beans are requisite for the supply of market, the climbers are not so proper for any general crop, on account of the great trouble they would require in sticking: besides, as before observed, they are not so saleable as the dwarf sorts, though they are equally good, if not superior to some of those kinds, for the table; the scarlet kind in particular claims preference. Observing, as all the climbing kind run up, by support, very tall, and branch out into lateral runners all the way, they require large scope to grow, so should generally be planted in drills four feet at least asunder.

The scarlet runner is also often employed as a flowery plant for the singularity of its flowers; sometimes, likewise, its white variety, planting them in patches alternately in any of the compartments; also to run over arbours, or up the sides of houses, or to form shady walks, &c. See their *Culture*.

The general season in which the main crops of all the sorts of Kidney-beans arrive to perfection in the full ground, is July, August, and September; or by early and late planting may have them from June till October: observing that a constant succession during these months is obtained by three or four different plantings, from the middle of April until July, as before hinted; which repetitions of plantings is absolutely necessary for the dwarf kinds, which do not continue bearing long, some not
more

more than a fortnight, others three weeks or a month; but as to the climbers, as they continue shooting and flowering all summer, until prevented by the cold in October or November, two different plantings of these sorts, one early in May, the other in June, will furnish an abundant supply of young beans during the whole season.

But, as before remarked, that in order to have a long succession of Kidney-beans for the table, different modes of culture is practised, as the raising both dwarfs and climbers in the full ground for the main crops; and by artificial heat, in different ways, for the dwarfs in particular, to have very early crops.

The particular culture, however, both of the dwarfs and climbing sorts, is exhibited below, each under its proper head.

Propagation and General Culture of the Dwarf Kinds in the Full Ground.

All the dwarf Kidney-beans, as well as climbers, are propagated by seed annually; and the season for planting the natural crops in the full ground, is spring and summer, at several different times from April until July, in order to obtain a daily supply of young beans during the whole season.

Observe to chuse the proper sorts for the different crops; that is, for the forward crops, you may use any of the first four early dwarf sorts, but the early white and negro kinds, are rather the best, and longest bearers; and for the main crops any of the larger dwarf kinds may be proper, though I should give preference to the speckled dwarf and the Battersea and Canterbury dwarf kinds, they being all plentiful bearers, and continue long in bearing, as observed in their description.

It must be remarked, as already hinted, that as Kidney-beans are exotics of a tender nature, they ought not to be planted earlier than April, when the weather is become a little settled, for the seed is not only impatient of cold moisture in the ground, and very subject to rot; but the young plants that happen to come up early, are often cut off, or greatly injured by the morning frosts, or cold cutting winds that frequently prevail in April and beginning of May. But towards the middle of April, if the weather is fine and dry, we may venture to plant pretty freely in a warm dry situation and light soil, for the early natural crops; and in the latter end of that month, or beginning of May, it is proper to begin to put in the first general crops

in the open quarters, &c. and so continue, planting some every fortnight or three weeks until the middle or latter end of July: whereby you will have a regular supply of young Kidney-beans for the table or market from about the middle or latter end of June until October, as aforesaid.

If, however, you are desirous to try to have them as early as possible in the full ground, you may put in a few about the beginning of April, in dry weather, close under a warm wall, to take their chance; and in a fortnight after put in a few more; if the first should fail, these may succeed; and if both are attended with success, one will succeed the other in bearing: though it is two to one against the success of the first: but as only a few should be planted so early, if they fail, it is only the loss of a little labour and seed, the ground will do again; and if they succeed and produce only a few, but a week sooner than common, they will be esteemed a rarity either for family use, or market.

They all succeed in any common soil of a garden, remarking however, that for the forward crops it is absolutely necessary to select a dry light soil, rejecting heavy and wet grounds, for in such a soil most of the early-planted seed would infallibly rot. Likewise for the early crops it is highly requisite to chuse a sheltered warm situation full to the sun, a warm south border, is a very eligible exposure; but for the main crops, any of the open quarters are proper.

The method of sowing or planting all the sorts is in shallow drills, from two feet to a yard asunder, and are all to remain where sowed. Observing the following hints.

For the early crop, chusing a warm border, and taking advantage of a dry day, draw neat drills with an hoe from north to south, two feet or thirty inches asunder, and near an inch deep, and to have a greater chance, I would draw also a drill close along under the wall, where practicable; in these drills drop the beans in a row along the bottom, only about an inch and a half asunder, as many of this early sowing may fail; covering them evenly with the earth, not more than an inch deep, for if covered deep at an early time, many are apt to rot, or at least rise stragglingly: as soon as they are covered in, lightly rake the surface smooth, and the work is finished. They will come up in about ten or twelve days or a fortnight: managing them as hereafter directed, and

and the plants will come into bearing in six or eight weeks.

For the main crops intended to be planted in May or June, &c. you may employ almost any situation; either in borders, or in an open exposure, though an open situation in any of the large quarters is the most eligible. Drawing drills two feet and a half asunder, and about one inch deep; or, if designed to plant rows of savoys or cabbage-plants between, as is often practised when necessary to husband the ground to the best advantage, the drills should be a yard asunder at least; drop the beans singly along the bottom of each drill, about three inches asunder, covering them in evenly with the earth about an inch deep, and finish with a light raking to smooth the surface. They will come up, at this season, in eight or ten days, and sometimes sooner in fine weather; and the plants will come into bearing plentifully in July and August.

In the above manner continue planting some every fortnight or three weeks until July, as we before advised; and you will have a plentiful daily supply of young beans, from June until Michaelmas or longer.

In planting the latter crops in June and July, when the weather proves very dry and hot, and the ground also very dry, it is proper either to soak the beans a few hours in soft water previous to planting, or instead of this let the drills for the reception of the beans be well watered, and immediately plant them as above, and cover them in the proper depth. Either of these methods is very advisable in dry weather in the heat of summer; it being necessary at such times to promote the free germination of the seed, to bring them up soon and regularly, which would otherwise rise in a straggling manner.

When the plants of all the above crops are come up, their general culture is as follows.

They are in general to remain where sowed or planted to yield their produce; observing to keep them clean from weeds by occasional hoeing in dry weather; and when the plants are advanced about three or four inches high, hoe up a little earth to their flanks on each side, which will forward their growth, and promote their strength: continuing the care of destroying weeds as often as their growth shall render it necessary; which is all the culture required for the dwarf Kidney-beans in

the full ground till they arrive at a bearing state, and their produce is fit to gather.

With respect to gathering the produce of these sorts of Kidney-beans, it should always be performed when the pods are quite young, or at least before they become large, and the beans in them attain any considerable size, as they would then be tough, stringy, and rank-tasted; and in order to continue the plants in bearing as long as possible, the gathering should be regularly repeated about three times a week; for by gathering the pods often and clean, as they become fit, the plants will blossom more abundantly, and continue fruiting more plentifully and longer accordingly.

Great quantities of these dwarf kinds are cultivated in the gardens and fields in the neighbourhood of London, for supplying the markets: where they are brought in large, flat, round baskets, called junks, from about half a bushel to a bushel size; which with the assistance of large cabbage leaves placed all around, are filled with the beans heaped up considerably, so as to have as much again at top as within; and are thus bound tight with cords, carried over and across, and in that manner carried securely to market in carts or waggons, &c. and there sold by the basket, at various prices, according to the size of the basket, and youngness and quality of the beans; but at first coming in they often fetch from five to eight or ten shillings per basket, and fall by degrees to two shillings or half a crown, or a little less or more according to the size of the basket, &c.

Propagation and Culture of the Climbing Kinds.

The propagation and culture of the climbing Kidney-beans, commonly called runners, is, they are all raised from seed annually in spring and beginning of summer, as observed of the dwarfs; and their general culture is nearly the same as for those sorts in the full ground; only they require more room to grow, and must have tall sticks or poles placed for their runners to twine or climb upon, as already noticed. Observing none of these climbing kinds are proper for early crops, neither in the open ground or hot-beds, so should be cultivated principally for summer and autumn crops, to come into bearing from July until Michaelmas.

Of these climbing kinds I should recommend the scarlet runner and its white variety, for the general crops, they being both extraordinary great bearers; continuing in perfection two or three months; and their pods, when even pretty large, remain green, fleshy, tender, and well flavoured. Some of the Dutch runners, and a few of the other climbers also merit culture.

The most eligible season to begin planting the main crops of all these sorts is the first or second week in May, if the weather is fine; for being of a delicate nature like the dwarfs, if planted earlier, both the seed and plants are subject to danger from the same causes; however, in a warm situation and dry soil, a few may be planted in the middle or latter end of April, to take their chance; but remarking, that for the general crops, the most successful season for planting is from May, as aforesaid, until the beginning of July; but if you plant principally the scarlet kind and variety, one planting in May or beginning of June, will come into bearing in July; and if you keep gathering the pods clean, according as they are fit for use, the plants will continue shooting, blossoming, and bearing abundantly until the end of September, or often until the end of October, or till destroyed by the cold; but two plantings of any of the sorts of runners, one in May and the other in June, or early in July, will furnish a very abundant supply the whole season of Kidney-beans.

All these climbing kinds will prosper almost any where in a garden, both in close and open situations: chusing principally a lightish soil, especially for the forward crops, and the richer the ground the better.

Observe, that as all the running kinds require support of some sort to climb upon, they should be planted either in wide rows, for the convenience of placing tall sticks or poles along each row for the runners of the plants to wind themselves for support; or planted against some sort of fence or treillage-work for the same purpose of training up and supporting the runners. When, however, it is designed to train them upon sticks or poles, let drills be drawn four feet, or four and a half asunder, especially for the larger kinds, and an inch deep; in which drop the beans, three or four inches apart: cover them in evenly with earth, and rake the surface smooth. The beans will sprout in a few days, and come up in less than a fortnight.

When the plants are three or four inches high, draw a little earth with an hoe up to their stems, to strengthen them and encourage them to send forth strong runners. At this time also cut down all weeds between the rows.

As soon as they begin to push their runners, begin to place some tall sticks or poles for them to ascend upon: as you place the sticks conduct the runners towards them, in a direction according to their natural mode of climbing, which is generally to the right or contrary to the sun's motion: they will thus naturally encircle the stick or poles, and ascend to their tops, even if ten or fifteen feet high, producing blossoms and fruit from bottom to top.

When intended to plant these sorts against fences for support, plant them in a row close along to the fence, and their runners, if against a wall or paling, may either be nailed up as they advance in length, or there may be some strong packthread string drawn from top to bottom at six inches distance; the plants will readily twine round them, and support themselves.

In gathering the produce of all these kinds, observe the same as of the dwarfs, to gather the pods whilst young and tender; and to continue the plants long in full bearing, always gather the pods clean as they become of proper size, and they will continue fruiting abundantly.

If you intend cultivating any of these climbing Kidney-beans as flowering-plants, the scarlet kind and its variety, as before suggested, are the proper sorts. Sow them any time from about the middle or latter end of April until July, in any of the compartments of the pleasure-garden, in patches, alternately scarlet and white sort, two or three beans in each patch, about an inch deep; and when the plants are up and begin to push runners, place tall poles or branchy sticks for them to climb upon: they will effect a very fine variety all summer until October.

They are also often employed to run over arbours, and to twine round the stems of trees; also to run up the sides of houses, or against walls, either upon poles, or upon packthread-strings, suspended from above, about which they will twine themselves many feet high, bearing abundance of flowers and fruit: they are likewise sometimes trained to form shady private walks, by means of high poles, arranged along each side, or by support of a
fort.

fort of treillage-work, ranging some tall stakes five feet asunder, railing them along the top with poles, or pan-tile laths; from which suspending strings to the ground, six or eight inches asunder, fastening them down with pegs: upon these strings the plants will climb and form a close hedge. Some persons are also curious enough to arch over the tops of such walks with any long, slight, pliable rods, poles, or hoops, so train the runners of the plants over to form a sort of a vaulted roof all the way along. Thus this fine climber may be trained in various ways according to fancy, both for use and pleasure, as may be observed in the numerous small pleasure-gardens in the environs of London; and those not accommodated with gardens, plant them in pots or boxes, to place in windows or balconies, &c. and train the plants upon strings, as just above observed.

Early Crops of the Dwarf Kinds by Artificial Heat.

To have Kidney-beans as early as possible, recourse is had to raising the dwarf kinds by aid of artificial heat, by two or three different methods, such as—By raising the plants in a hot-bed, an inch or two high, and then plant them out into a warm border—By raising and continuing the plants in a hot-bed to bear their crops—By aid of a hot-house.

1. **By** raising in a hot-bed for transplantation into warm borders.—By this method we may forward Kidney-beans a fortnight earlier than those raised entirely in the full-ground: for this purpose, towards the latter end of March, prepare a moderate hot-bed, a foot and half depth of dung, covered either with a frame or hand-glasses, or arched over with hoops or rods, to be covered with mats; earthing the bed with fine, light, rich mould, six inches deep; then having some seed of the early dwarf sorts, sow them pretty close for transplantation, either all over the surface, an inch or two apart, covering them with earth about half an inch deep; or in small drills two or three inches asunder, and cover them the above depth; though it will be rather most eligible to plant them in the drills by pairs, at three inches distance from pair to pair, and the plants can be more readily transplanted two and two with balls of earth to their roots; or where only a few is wanted, they may be sowed in large pots, at about an inch distance and half a one

deep, and the pots plunged into any hot-bed; and when the plants come up, the pots may be removed by degrees into the full air, to harden the plants for transplantation. But it is a good method to plant a quantity of beans in small pots (thirty-twos), three in each pot, plunging the pots in a hot-bed, and when the plants are fit for transplantation, they can be readily turned out of the pots with the whole ball of earth about their roots so as not to feel their removal.

However, in raising the plants in either of these methods for transplantation in the full ground, your attention is particularly necessary to inure them gradually to the full air, by taking off the covers of glasses or mats in all mild weather, and only cover them in cold nights; but as they advance in growth, and the weather becomes warmer, they must be exposed by degrees to the full air, day and night, to harden them properly previously to their final transplantation. Observing also to allow them frequent moderate refreshments of water, and let them enjoy the benefit of warm showers.

When they have shot out their proper leaves an inch or two broad; and all danger of frosty mornings and other bad weather is apparently over, proceed to plant them out into a warm border, under a wall or other fence. Observing particular care to take them up with their roots as entire as possible, and with as much earth as will hang about them, those especially that are raised by pairs, may be readily taken up, each pair with a ball of earth; and those raised in small pots by threes may also be easily turned out with the whole ball of earth entire; and as to the mode of planting them, those which were raised close together, and could not readily be taken up with balls, may be planted by dibble, in rows two feet asunder, forming shallow drills for their reception, in which set the plants three or four inches apart; but those with good balls about their roots, should be holed in with a trowel; and if some of those are also disposed in patches, two or three plants in each, so as to be covered occasionally in cold nights with hand-glasses, it will be found very beneficial in forwarding their growth. As soon as they are planted, in either method, give a moderate watering to settle the earth close about the roots, and let it be repeated in dry weather as there may be occasion, till the plants have taken fresh-root in their new quarters.

After this keep them clean from weeds, and when a little advanced in growth, draw some earth lightly up about their shanks; and as the warm season advances, if it proves hot and dry, refreshments of water will forward and strengthen the growth of the plants.

Thus this crop of Kiney-beans will sometimes arrive to a bearing-state a fortnight sooner than those raised entirely in the natural ground.

2. By Hot-beds entirely.—To have Kidney-beans as early as possible, is effected by raising the small early dwarfs in hot beds, and continuing them there to attain perfection, whereby they may be forwarded to a bearing state in April and May: the method is this, proceed about the beginning or towards the middle of February, to make a dung hot-bed, for one, two, or more three-light frames, about two feet and a half high in dung: and when the great heat and steam are a little abated, earth the bed with light, rich, dry mould, six or eight inches thick, for the reception of the seed (see HOT-BEDS); then having some seed of the small early dwarf kinds, draw drills from the back to the front of the bed, near an inch deep, and about fifteen or eighteen inches asunder; here place the beans two or three inches apart, and cover them evenly with the earth the above depth; then put on the lights: but tilt them behind an inch or two high daily, so give vent to the steam; and when the plants appear, continue every day to admit air to them at all opportunities, in proportion to the temperature of the weather, and heat of the bed, to prevent their drawing weak, and to promote their strength as they rise in height; bestow also at this time moderate refreshments of water in sunny days; and when they are two or three inches high, apply a little earth to their shanks; likewise support a moderate heat in the bed during the cold weather, by occasional linings of hot dung: observing according as the plants advance in growth, and the warm season encreases, augment gradually the portion of fresh air daily to harden them by degree, so as almost to be fully exposed occasionally in very warm days, especially when beginning to blossom, but keep them close on nights: continue also the care of frequent light waterings, which must be increased in quantity as the plants advance in size, particularly when they are in blossom, and in a fruiting-state: in their ad-

vanced growth, if they press much against the glasses of the frame, it is proper to raise it at bottom two or three inches, to give room at top for their free growth; which being necessary to promote a plentiful bloom, for furnishing a proper crop of Beans equal to the expence and trouble requisite in the culture of such early crops.

They will thus arrive to full growth, and produce early young Beans for the table in April and May.

But to obtain a constant succession of early Kidney-beans till the natural-ground crops come in, we should proceed with another crop in hot-beds, as above, in three weeks after the first hot-bed is made.

In default of frames for the above purposes, you may in March effect it with occasional coverings of mats; that is, make a hot-bed about two feet high of dung, earthing it directly six or seven inches thick, and sow the beans as before directed; then arch the bed over with hoops, &c. and cover every night, and all bad weather, with mats: but admit the free air every mild day, gradually hardening the plants as they acquire strength, and give occasional waterings: thus they will furnish beans early in May.

3. By Aid of a Hot-house.—If you are accommodated with a hot-house or stove, early Kidney-beans may be obtained with very little trouble at almost any time in winter or spring: raising them in pots, or long narrow trough-like boxes, about a yard long and eight or ten inches broad at top; placing either any where in the hot-house, the plants will succeed, observing as below.

The proper kinds for this purpose is the early white or liver-coloured dwarfs: the speckled dwarf also succeeds very well, and continues long in bearing.

Therefore any time in winter or early in spring, you may fill some large pots (sixteens or twenty-fours) or boxes with light rich earth, and place them upon the top of the wall which surrounds the bark-bed, or upon shelves or in any part of this department where convenient; and in each pot plant four beans, near an inch deep; or, if boxes, plant the beans along the middle, in a sort of double row, triangular-ways, about four inches asunder, and the above depth: they will soon germinate, and in a few days appear above ground: when they, however, begin to sprout, it is proper to moisten the mould with a little water, which will facilitate

cilitate the eruption of the plants out of the earth.

Their culture here is very easy: when they are come up, give frequent waterings, which will be requisite three times a week, at least, in this department, as the earth will dry very fast; but always keep it moderately moist, and the plants will blossom freely, and produce a plentiful crop of beans, often in as great perfection as in the full-ground crops.

They should be gathered often, which is the way to continue the plants long in bearing.

A regular succession of young Kidney-beans may be obtained in this repository for several months; by repeated sowings at about three weeks interval, so as to have young plants advancing in pots or boxes in two or three different degrees of growth succeeding one another.

But as sometimes we are straitened for stove-room, it may be proper to plant the beans for succession crops in small pots (forty-eights) three beans in each, and as these will take up but little room, they may be stowed any where close together, or between the other larger pots; the plants will come up and be advancing in growth, so as when those of the preceding crops are going off, these may be readily turned out of the small pots with the whole ball of earth about their roots, and replanted into large pots, &c. to remain for fruiting.

By this practice you will gain a month's growth in the plants, and you may thereby have a constant succession of beans for the table.

Saving Seeds of all the Sorts.

With respect to saving seed of Kidney-beans, all the sorts ripen plenty in August and September.

To have perfectly good seed, it is proper to sow a sufficient quantity in rows on purpose, suffering the whole crop of the plants to remain without gathering any for use: you will thus have the seed ripen betimes, and in the highest perfection, which is essentially necessary for those who design the seed for public supply.

In private gardens, however, and many others, they often after having gathered the flower as it were of the principal crops, leave the latter produce of them to grow for seed; which, although it may be tolerable good, it

is not always so large, plump, and fine, as in the former method.

When the seed is quite ripe, which is easily known by examining a few of the pods, pull up the plants, and spread them loosely along in rows, turning them daily that the beans may dry and harden well, which when effected, either thresh them out directly, or lay them up in some dry loft or other room till convenient; and when threshed out, and cleared from the rubbish, spread them upon some clean airy floor, or some such place in the dry to harden perfectly, then put them up in bags for next year's use.

It is of much importance to have change of seed once in two or three years; that is, if you always save your own, it is adviseable either to change a quantity of seed with some friend at a distance, or purchase a fresh supply once in the above mentioned time; for by saving seed always in the same ground, it will degenerate, the plants will become every year weaker, and deficient in bearing. But by change of seed from some distant place, as above, you will have the different sorts always in their ultimate state of perfection.

PHILADELPHUS, *Syringa*, or Mock-Orange.

Two hardy, deciduous, flowering shrubs compose this genus, furnishing some varieties; all noted floriferous plants for the shrubbery, rising several feet high, branching out into bushy heads, decorated with large oval leaves, and numerous clusters of tetrapetalous white flowers.

Class and order, *Icosandria Monogynia*.

Characters.] CALIX, is monophyllous, acutely four-parted, and persistent. COROLLA, four large, roundish, plane, spreading petals. STAMINA, twenty or more awl-shaped filaments, having erect four-furrowed antheræ. PISTILLUM, a germen under the corolla, slender four-parted style, crowned by simple stigmas. PERICARPIUM, an oval-acute-pointed, quadrivalved, quadrilocular capsule, containing numerous small oblong seeds.

There are but two species, both hardy deciduous shrubs, originally of foreign growth; but one of which has been long a resident of our gardens, is a very noted ornamental flowering shrub, comprising some varieties.

The species are;

¹PHILADELPHUS *Coronarius*.

Coronarius-flowered *Syringa*, or *Common Mock-Orange*.] Rises with many shrubby, slender,

slender, brown stems, of a brittle and pithy nature, branching five or six feet high, the branches by opposite pairs, alternately of contrary directions, jointed, and covered with a brown smooth bark; large oval-spear-shaped, rough, slightly-indented, opposite leaves; and at the axillas and termination of the branches many large loose bunches of white, very fragrant flowers; appearing in May and June.

The flowers, both in figure and scent, resemble those of the orange-tree: hence the appellation Mock-orange.

Varieties.] Dwarf coronarius Syringa—double-flowered dwarf. Both these varieties grow only about two or three feet high, garnished with small leaves, and the flowers generally rise singly, but the plants rarely flower.

²PHILADELPHUS *Inodorus*.

Inodorous, or Scentless Carolina Syringa] Rises with a shrubby stem, branching twelve or fourteen feet high; oval-spear-shaped, entire leaves; and the branches terminated by large, white, scentless flowers.

Both these species of *Philadelphus* are elegant furniture for the shrubbery compartments: the first sort, however, and varieties, are the principal kinds at present in our gardens, the second sort being more rare in this country; but both the species are equally hardy, and will succeed in almost any soil and situation, and produce a profusion of flowers annually, particularly the *Coronarius Syringa*, which is in a manner covered with bloom, and exhibit a very ornamental appearance for a month or six-weeks, and emits an odoriferous scent widely around.

Their Propagation, &c.

The propagation of all the sorts is remarkably easy—by suckers—layers—and cuttings.

By Suckers.—All the sorts send out numerous suckers from the root, which may be separated from the parent plant, any time in open weather from October till March, and planted in nursery-rows, to remain one, two or more years to obtain strength, and then may be transplanted into the shrubbery.

By Layers.—Any time from October till March lay a quantity of the young branches, they will be rooted and fit for transplantation in autumn following, managing them as directed above for the suckers.

By Cuttings.—In October or November plant a quantity of the young shoots in any

shady border, many of them will form proper plants in one year.

PHILLYREA, (*Phillyrea*) Mock-privet.

This genus consists of beautiful ever-green shrubs for adorning the shrubbery-compartments; rising from about six or eight to twelve or fourteen feet high, branching numerously and diffusely into bushy heads; closely garnished with oval moderate-sized leaves, and clusters of small monopetalous funnel-shaped greenish-white flowers.

Class and order, *Diandria Monogynia*.

Characters.] CALIX, is monophyllous, four-parted at top, and permanent. COROLLA, is monopetalous and funnel-shaped, with a short tube below, and the limb or upper part divided into five revolute segments. STAMINA, two short filaments with simple erect antheræ. PISTILLUM, a roundish germen, slender style, and a thickish stigma. PERICARPIUM, a globose unilocular berry, having one large globular seed.

There are but three species, all of which are hardy ever-greens of the shrub kind; but the *Phillyrea* and a species of *Rhamnus*, called *Alaternus*, are often mistaken for each other, on account of the great similarity in their general port or habit; there is, however, this very obvious distinction, the leaves of the *Phillyrea* always grow opposite by pairs; those of the *Alaternus* stand singly in alternate arrangement; besides there is a classic difference in their fructification: the former having only two filaments, and the latter five; so that one is of the class *Diandria*, the other *Pentandria*. See RHAMNUS *Alaternus*.

The species of *Phillyrea* are:

¹PHILLYREA *Media*.

Middle Phillyrea, or oval-leaved Mock-Privet.] Hath a shrubby upright stem, branching diffusely ten or twelve feet high; oval-lanceolate, almost entire, smooth, opposite leaves; and at the axillas of the branches, clusters of small greenish-white flowers.

Varieties.] Privet-leaved—olive-leaved.

²PHILLYREA *Latifolia*.

Broad leaved Phillyrea.] Hath a strong, shrubby, upright stem, branching erectly about twelve or fourteen feet high; oval-cordated, sharply-ferrated, opposite leaves; and at the axillas clusters of small greenish flowers.

Varieties.] Prickly ilex-leaved—slightly-ferrated leaved.

³PHIL-

³PHILLYREA *Angustifolia*.

Narrow-leaved Phillyrea.] Hath a shrubby stem, branching moderately about eight or ten feet high; long, narrow, spear-shaped, very entire, opposite leaves; and at the axillas of the branches clusters of small whitish flowers.

Varieties.] Rosemary-leaved—lavender-leaved—striped-leaved.

All these three species and respective varieties, flower annually in March; the flowers are universally monopetalous hermaphrodites, small and greenish, so make no show; and in all the sorts are succeeded by small round berries, ripening in autumn to a black colour, each containing one seed. See the *Characters*.

They are all delightful ever-green shrubs, of a free easy growth, with long slender branches, covered with a brownish or greyish bark, and closely garnished with their beautiful foliage the year round; which are generally of a thick, stiff consistence, with a smooth glossy surface, appearing very ornamental at all seasons; so that the shrubs are finely adapted to all the shrubbery compartments in assemblage with other ever-greens: they also appear well when detached here and there as single objects; and they formerly were often planted for internal hedges, to divide the quarters of wilderness-works, &c. in which they have a beautiful effect: they are also well calculated for planting to hide any naked or old disagreeable wall, &c. especially the boundary walls of fore courts or other principal parts; in which they may be intermixed with a *Alaternus* for a variety, training their branches close to the wall, and they will soon spread and cover it effectually; when they may either be suffered to branch according to nature, or may be trimmed close every year in spring and summer.

No good shrubbery, however, should be without a collection of these fine ever-greens, disposed in the most conspicuous points of view, there suffered to branch in their own rural manner, only just regulating with your knife any very straggling branches.

Their Propagation.

The propagation of all the three species of this genus is by seed and by layers.

By Seed.—This should generally be sowed in autumn, soon after it is ripe, and probab-

ly it will come up the spring following; tho', for the most part, the seed of all these plants remain until the second spring before they germinate; chuse, however, a light sandy soil for the reception of the seed, which sow evenly, either all over the surface, covering it with earth an inch deep, or in shallow flat drills about the same depth: keep the earth very clean from weeds, both before and after the appearance of the seedlings: giving also frequent waterings, in dry weather. Observing, it is proper to let them have two years growth in the seed-bed: remark, however, at the approach of winter, it will be proper to arch the bed over with hoops, or rods, in order to shelter the seedlings with mats in time of severe frost, for they are tender whilst young; but after the second summer's growth they become tolerably hardy, and may then be planted out either in autumn following, or in the ensuing spring, February or March, when the weather is settled, planting them in nursery-rows to remain two or three years, or more, to acquire due size for the shrubbery.

By Layers.—Autumn is the best season, though it may also be performed in winter and spring; chusing the young shoots, which lay either by slit-laying, or by twisting at a joint, and they will be rooted by autumn following; when they may be separated from the parent plant, and planted in nursery-lines, to remain till fit for the shrubbery-plantations.

PHLOMIS, Jerusalem Sage, and *Leonurus*.

This genus furnishes some eminent shrubby and under-shrubby ever-greens, for the pleasure-ground and green-house collection; all of which are of upright growth, garnished mostly with simple entire leaves, in some sorts assuming a beautiful hoary whiteness, and monopetalous, ringent, very ornamental flowers.

Class and Order, *Didynamia Gymnospermia*.

Characters.] CALIX, is monophyllous, tubular, oblong, five-angled, and permanent. COROLLA, is monopetalous, with an oblong tube, ringent above, having the upper lip oval, arched, and reflexed; and the under three-parted, the middle part large and obtuse. STAMINA, two long and two short filaments, and oblong antheræ. PISTILLUM, a quadripartite germen, a style the length of

of the stamina, and a bifid acute stigma. PERICARPIUM, none, four naked seeds lodged in the calix.

There are many species, but not more than four common to the English gardens, all of which are of a shrubby nature, two of them hardy for the shrubbery, and two for the green-house.

Hardy Kinds for the Shrubby.

These sorts are ever-greens, and are remarkable in having their branches and leaves of a hoary white colour, in which they exhibit a singular variety.

¹PHLOMIS *Fruticosa*.

Shrubby Yellow Phlomis, commonly called Jerusalem Sage.] Hath a shrubby thick stem, branching irregularly four or five feet high, the stem and older branches having a loose ragged bark, and the young branches four-cornered and woolly; roundish-oblong, crenated, hoary-whitish leaves, by opposite pairs on woolly foot-stalks; and from the upper parts of the young shoots, large whorled bunches of yellow flowers. In June, July, and August.

Varieties.] Common broad-leaved—narrow-leaved—dwarf Cretan sage-shrub.

²PHLOMIS *Purpurea*.

Purple Portugal Phlomis.] Hath an under-shrubby stem, branching four feet high, having slender, angular, white branches, oblong, cordated, hoary leaves; and from the joints of the branches whorls of deep-purple flowers. In June and July.

Both these species prosper in the open ground, and as they retain their hoary-white leaves all the year, are highly ornamental in shrubberies; they, however, were formerly kept in pots, and treated as green-house plants; but this is unnecessary unless for variety, for they will succeed in any of the shrubbery compartments the year round.

Green-house Kinds.

These sorts were formerly of the genus *Leonurus*; but modern botanists have ranged them as species of *Phlomis*.

³PHLOMIS *Leonurus*.

Leonurus, or Lion's-Tail, commonly called African Scarlet Leonurus.] Rises with a shrubby branching stem seven or eight feet high, having four-cornered branches; spear-shaped, serrated, opposite leaves; and towards the ends of the branches, whorls of close-sitting

scarlet flowers, having ten-angled cups indented into ten parts; flowering in October and November.

Variety.] With variegated leaves.

⁴PHLOMIS *Nepetæfolia*.

Nepeta-leaved Cape Leonurus.] Rises with a shrubby branching stem, a yard high, having four-cornered branches; oval leaves, opposite by pairs; and whorls of scarlet flowers, having ten-angled cups, indented into seven equal parts; flowering in October and November.

All these four species of *Phlomis* have great merit as ornamental plants, both as ever-greens, and for the beauty of their flowers, as they all flower very ornamentally every year in our gardens; those of the *Leonurus* kinds in particular, make a fine appearance; but the flowers of all the sorts are numerous, and being collected into large verticilli towards the ends of the branches, are very conspicuous; they are universally monopetalous, ringent, and hermaphrodite. See the *Characters*.

The two hardy kinds are choice ornaments for the shrubbery, their hoary branches and leaves will exhibit a delightful contrasted variety in assemblage with other different ever-greens; suffering them to branch in their own way.

The two green-house kinds highly merit culture for the beauty of their flowers in particular; they must be potted in rich earth, and managed as other shrubby exotics of the green-house collection.

Their Propagation.

The propagation of all the sorts is by layers and cuttings.

By Layers.—The two hardy sorts in particular grow freely by layers, chusing the young branches, and lay them in the common way any time in the year, they will readily strike root, and commence proper plants by autumn after, when they should be transplanted.

By Cuttings.—Plant a quantity of young shoots in spring or summer, in a shady border; give plenty of water in dry weather; many of them will root and make good plants, by the next autumn.

Remark, however, the cuttings of the green-house kinds, should, if in spring, be planted in pots, in order to be continued in shelter until May; or if the pots are plunged in a hot-bed it will greatly forward their rooting:

ing; though young shoots planted in June or July in a bed or border of rich earth, many of them will take root, but may be much forwarded if covered down close with hand-glasses, removing the glasses when the cuttings begin to shoot.

PHLOX, *Lychnidea*, or Bastard-Lych-nis.

The plants of this genus are herbaceous, fibrous-rooted, flowery perennials for adorning the pleasure-garden; rising with upright annual stalks, from one to two or three feet high, garnished with spear-shaped and oval leaves, and terminated by clusters of monopetalous, hypocrateriforme, purple or reddish flowers.

Class and Order, *Pendandria Monogynia*.

Characters.] CALIX, is monophyllous, quinque-dented, and permanent. COROLLA, is monopetalous, and hypocrateriforme, with a cylindric crooked tube, and a plane limb, divided into five obtuse segments. STAMINA, five filaments within the tube, and antheræ placed in the chaps of the corolla. PISTILLUM, a conical slender style, and trisid acute stigma. PERICARPIUM, an oval, trigonal, trivalvular, trilocular capsule, having one oval seed in each cell.

There are about nine or ten species, the most material of which for our purpose are the following six sorts.

¹PHLOX *Glaberrima*.

Smooth Virginia Lychnidea.] Hath creeping perennial roots; upright, herbaceous, smooth stems, near two feet high; narrow, spear-shaped, smooth, opposite leaves; and the stalks terminated by corymbose clusters of reddish flowers. Appearing in June or July.

²PHLOX *Carolina*.

Carolina shining-leaved Lychnidea.] Hath a strong, creeping, perennial root; upright rough stems, two feet high; spear-shaped, stiff, shining, sessile leaves, by pairs opposite; and the stalks terminated by a flat corymbus of deep purple flowers. Appearing in July.

³PHLOX *Paniculata*.

Paniculated American Phlox, or Lychnidea.] Hath perennial roots; upright, herbaceous, branchy stems, two or three feet high; spear-shaped, rough-bordered, close-fitting, opposite leaves; and the stalks terminated by a paniculated corymbus of pale-purple flowers. Appearing in July and August.

⁴PHLOX *Divaricata*.

Divaricated Blue Virginia Phlox, or Lychnidea.] Hath perennial roots; herbaceous, slender, weak, divided stems, having the branches divaricated or spreading from each other; broad, spear-shaped, sessile leaves, the upper ones placed alternately; and pedunculi by pairs, supporting loose bunches of light blue flowers. Appearing in May and June.

⁵PHLOX *Maculata*.

Maculated or Spotted stalked Virginia Phlox.] Hath a perennial root; upright, taper, rough, purpleish, white, and red-spotted stems, a yard high, branching by opposite pairs; spear-shaped, smooth, amplexicaule, opposite leaves; and the branches terminated by a corymbus of bright-purple flowers. Appearing in July and August.

⁶PHLOX *Pilosa*.

Hairy Virginia Phlox.] Hath a perennial root; upright, single, slender stalks, about a foot high; spear-shaped, acute, hairy, sessile leaves; and the stalks terminated by a corymbus of light-purple flowers. Appearing in June and July.

All these six species of *Phlox* are hardy perennials, originally from North America; durable in root, but renew their stalks annually. Considered as flowery plants, they merit culture in every good garden, for they flower very ornamentally: the flowers are all monopetalous, salver shaped, and collected into large conspicuous bunches at top, continuing three or four weeks in beauty, but are rarely succeeded by ripe seeds in England.

They will prosper in any of the compartments of the pleasure-garden, but are particularly well adapted for embellishing the principal borders, &c.

Most of the sorts may be had at the public nurseries; and the proper season for removing them is in autumn when their stalks decay, or early in spring before they begin to shoot.

Propagation of all the Sorts.

The propagation of all the sorts is by parting the roots, and by cuttings of their young stalks.

By Parting their Roots.—Autumn, when their stalks decay, is the best season for this. Most of the sorts afford a sufficiency of offsets for propagation, which are to be separated in the usual way, not too small; planting the

the strongest slips where they are to remain to flower, and the smaller in nursery-rows for a year to get strength.

By Cuttings.—If any sorts furnish but a sparing supply of off-sets from the roots, recourse may be had to cuttings of the young stalks: May, when the shoots are but a few inches high, is the proper season; cutting off a quantity close to the ground, and trim off their tops; then plant them in a bed or border of good earth, or in large pots, several in each; giving water directly, repeating it often in dry weather, with occasional shade from the sun till rooted; or, if they are planted close, and covered with hand-glasses it will forward their rooting; removing the glasses when they began to shoot.

PHOENIX, Great Palm, or Date-tree.

It consists of one species only, an ever-green tree of great height and singularity, an exotic of India, and retained here in our stoves for variety.

Class and order, *Diœcia Triandria*.

Characters.] CALIX, male and female spadiceous flowers on different plants, having an univalvular general spatha, protruding a branching spadix, composed of many florets, each with a three-parted perianthium. COROLLA, three oblong concave petals in the males, and in the females is composed of six parts. STAMINA, three very short filaments, and oblong linear antheræ. PISTILLUM, a roundish germen, awl shaped style, and acute stigma. PERICARPIUM, an oval, baccaceous, unilocular fruit, containing one nearly oval, very hard seed.

The species is:

PHOENIX *Dactylifera*.

Dactyliferous, or Date-bearing Palm; Greater Palm, or Date-tree] Rises with an upright, straight, undivided, branchless trunk, from fifty to an hundred feet high, studded with rugged protuberances, the vestiges of fallen leaves, and the middle filled with pith; no proper branches, but crowded at top with a vast columnar, spreading cluster of pinnated branch-like leaves, six or eight feet long, composed of long, sword-shaped, complicated, stiff, alternate folioles; and amidst the leaves very long spadiceous clusters of whitish flowers; succeeded in the female-plants by clusters of large oval berries.

The berries of this tree are the dates of the shops, imported hither from Africa and the Eastern countries.

This singular tree, like the rest of the Palm tribe, have no other branches than its large leaves, each of which being a composition of a leaf and branch, always arising from the top, and as the old leaves fall, the stem forms itself and advances in height; but although the leaves grow very tall in a few years, yet the stem advances but slowly, and can never be expected to arrive at a flowering and fruiting-state in this country; it, however, merits a place in our hot-house collections for its singularity.

It must always be kept in pots of rich earth, and placed constantly in the stove; and if there plunged in the bark-bed, it will make the greater progress: observing to give proper waterings, and shift it occasionally into larger pots.

The propagation of this plant is by seed, procured from abroad, which sow as soon as possible, in pots of light rich earth, and plunge them in a tan hot-bed, or in the bark-bed in the stove; giving moderate waterings, they will soon come up, which, when a few inches high, prick into separate small pots, plunge them in the hot-bed, or in the bark-bed, as aforesaid; where they may remain, giving frequent waterings, and shift them into larger pots, according as their progress of growth may require.

PHYLICA, Bastard Alaternus.

This genus is composed of shrubby ever-green exotics of Africa, for the green-house collection; are of branchy growth, obtaining three or four feet stature, garnished with small ever-green leaves; and clusters of pentapetalous whitish flowers at the ends of the branches.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, many florets collected into a head, situated in one common receptacle, each having a monophyllous, five-parted, permanent cup. COROLLA, each floret is composed of five acuminate squamulæ situated in the base of the divisions of the calix. STAMINA, five small filaments under the squamulæ, and simple antheræ. PISTILLUM, a roundish, trilobed, trilocular, trivalvate capsule, having a roundish seed in each cell.

The most material species in the English gardens are the three following:

¹PHYLICA *Ericoides*.

Heath-leaved Phyllica.] Hath a low shrubby stem, divided into many spreading branches, forming

forming a bushy head, about three feet high; closely garnished with very narrow, small, heath-like, close-fitting leaves, in verticilli round the branches; and all the branches terminated by close clusters of white flowers; in autumn and winter.

²PHYLICA *Plumosa*.

Plumose Phylica.] Hath a low shrubby stem, divided and branching about a yard high; narrow awl-shaped leaves, hairy at top; placed alternately on every side of the branches, and the branches terminated by close downy heads of fringed white flowers; in autumn and winter.

³PHYLICA *Buxifolia*.

Box-leaved Phylica.] Hath a shrubby erect stem, branching four or five feet high; small oval, obtuse, firm, smooth, sparsely leaves, downy underneath; and the branches terminated by small heads of greenish flowers; in autumn and winter.

All these species are durable in root, stem, and branches, and retain their leaves all the year.

They being natives of Æthiopia, and other parts of Africa, are somewhat tender, requiring shelter here in winter, so must always be kept in pots, and placed among the greenhouse exotics, where they will effect a very agreeable variety at all seasons, and flower annually great part of autumn and winter; but do not produce seed in England.

Their propagation is chiefly effected by cuttings and slips of the young shoots.

In spring, about March or April, take off a quantity of young cuttings, or slips of the small shoots, plant them in pots of rich earth, which plunge in a hot-bed, or in the bark-bed in the stove; giving frequent waterings, and occasional shade from the sun, they will soon emit roots, and become proper plants fit for potting off separately in autumn:

Or young cuttings or slips planted any time in summer, particularly June and July, in pots as above, and placed under a hot-bed frame, or covered close with hand-glasses, watered and shaded, they will also grow; but will not be so forward as those of the spring-planting.

PHYSALIS, (*Alkekengi*) Winter Cherry.

This genus consists of herbaceous and shrubby ornamental plants, for the pleasure-ground, green-house, and stove, mostly of upright, branchy growth; garnished with oblong, oval, and heart-shaped leaves; and monopetalous, rotaceous flowers.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, is small, monophyllous, pentagonous, semi-quinquefid, swelling, and persistent. COROLLA, is monopetalous and rotated, with a very short tube, and the limb large, plicated, and quinquefid. STAMINA, five small, awl-shaped filaments, having erect connivent antheræ. PISTILLUM, a roundish germen, filiforme style, and obtuse stigma. PERICARPIUM, a small roundish bilocular berry, lodged in a large swollen, pentagonous, coloured calix, having many reniforme seeds.

There are about eight or ten species of this genus, consisting of hardy herbaceous perennials and annuals for adorning the pleasure-garden, and shrubby plants for the greenhouse and stove collections.

Hardy Herbaceous Perennial Kinds.

Of these kinds there are only two species for our purpose, both exotics of foreign countries, but hardy enough to live here in the open ground, one of which, *Common Winter Cherry*, hath been long a resident in our gardens.

¹PHYSALIS *Alkekengi*.

Alkekengi, or Common Winter Cherry.] Hath long, creeping, perennial roots; many upright, jointed, herbaceous stems, a foot and a half high, branching at bottom; garnished with large, oblong, acute, entire leaves, by pairs from the same side of the stalk; and at the axillas, long slender pedunculi, terminated by white flowers; succeeded by round red berries, inclosed in the large inflated bladder-like calix.

²PHYSALIS *Viscosa*.

Viscous Virginia Winter Cherry.] Hath a creeping perennial root; many upright herbaceous stems, about a foot high, paniculated above; obtuse, repand, downy leaves by pairs; and at the axillas yellowish flowers; succeeded by greenish-yellow viscous berries.

Both the above species flower in June or July, and the berries ripen in autumn; those of the first sort resemble common red cherries, and exhibit a very ornamental appearance in autumn.

The berries of the first sort (*Alkekengi*) are used with success against the gravel and stone, and the heat of urine; and may be eaten raw, or boiled in milk, and sweetened with sugar.

P H Y

Annual Kinds.

There are two species of the annual kind proper for our collection, both exotics, but hardy enough to prosper in the open borders.

³*PHYSALIS Angulata.*

Angular Winter Cherry.] Rises with an upright firm stem, divided into numerous angular smooth branches, growing two or three feet high; oval indented leaves; and at the axillas and ends of the branches small white flowers, succeeded by large yellowish berries.

Varieties.] There are many varieties differing in some respect or other, but all retain the specific difference of having angular branches, and smooth oval leaves.

⁴*PHYSALIS Pubescens.*

Pubescent, or Downy Winter Cherry] Rises with a short stem, dividing low into numerous spreading branches, oblong, downy, viscid leaves; and at the axillas greenish-yellow pendulous flowers; succeeded by large yellowish berries.

Varieties.] There are many varieties differing from one another in some peculiar mode of growth.

Both these species and respective varieties flower in June and July, and the berries ripen in autumn.

Shrubby Green-house Kinds.

Of these kinds there are but two species common to the English gardens, both of which are of a shrubby nature; and being exotics of warm countries require shelter of a green-house here in winter.

⁵*PHYSALIS Semnifera.*

Semniferous Sicilian Winter Cherry.] Hath a shrubby stem, branching three or four feet high, with the branches erect; oval, spear-shaped, downy entire leaves; and at the axillas greenish-white flowers in clusters; succeeded by small red berries.

⁶*PHYSALIS Flexuosa.*

Flexuose Indian Winter Cherry.] Hath a shrubby stem, branching four or five feet high, with long flexuose branches; oblong, almost close-fitting leaves; and at the axillas clusters of small greenish-yellow flowers; succeeded by purpleish berries.

Both these plants flower in June and July, and in favourable, warm, dry seasons the berries ripen in autumn.

P H Y

Hot-house Kinds.

There are two species for the stove, both of them shrubby; and being natives of the hot parts of India, &c. require the constant aid of a stove to preserve them in this country.

⁷*PHYSALIS Arborescens.*

Arborescent, or Tree like Campeachy Physalis.] Hath a woody upright stem, dividing and branching out at top ten or twelve feet high; oval hairy leaves alternate below, and opposite above; and at the axillas almost solitary, yellowish, revolute flowers; succeeded by small red berries, in dark purple bladders.

⁸*PHYSALIS Curassavica.*

Winter Cherry of Curassao.] Hath an under-shrubby branching stem, rising two or three feet high; oval, downy, alternate leaves; and at the axillas small, close-fitting, yellow flowers, rarely succeeded by berries in England.

The above eight species of *Physalis* are the chief sorts at present in our gardens; they flower principally in June, July, and August: the flowers are small, and consist each of one rotated, or wheel-shaped, quinquefid petal; which in most of the species are succeeded by ripe berries inclosed in the calix, forming an inflated, or bladdery-like, coloured over, opening at top and discover the fruit, and appears very beautiful in the autumn season.

All the sorts are retained in curious gardens as plants of ornament.

The herbaceous species, both of the perennial and annual kinds, succeed in the open ground; the former all the year, and the latter in summer, and make a pretty appearance, especially in autumn, with their beautiful cherry-like red berries: observing, however, that as the second sort, *Physalis Viscosa*, is rather of a tender nature, some plants should also be kept in pots, to move to occasional shelter of a garden-frame, &c. in frosty weather.

The shrubby kinds, both of the green-house and hot-house, must always be kept in pots for moving to shelter of those conservatories, and managed as other shrubby exotics of each collection.

The Propagation of all the Sorts.

The propagation of all the sorts is easily effected by seed; and the herbaceous perennials likewise by parting the roots; and the shrubby

shrubby kinds of the green-house and stove also by cuttings; see each sort under a separate head, as follows:

Herbaceous Perennial Kinds.—These sorts may be multiplied abundantly by seed, and by parting the roots. 1. By Seed.—Sow it in autumn as soon as ripe, or in spring, in a bed or border of light, dry soil, covering them half an inch deep; and when the plants are come up about two or three inches high, prick them out in nursery-rows to stand till autumn, then transplant them where they are to remain. 2. By parting the Roots.—They multiply plentifully by the root, which may be parted any time in open weather from October till March; every slip having fibres at bottom, and a bud at top, will form a good plant.

Annual Kinds.—Both these sorts are raised from seed annually in spring, in April, either in a warm border, or in a hot bed, to bring them more forward into flower: sow the seed about a quarter of an inch deep; and when the plants are come up about three inches high, prick them out, which if also in a hot-bed for a month, it will forward them greatly; hardening them gradually to the open air, then transplant them in moist weather with balls, into the borders or places where they are to flower.

Green-house Kinds.—They are best propagated by seeds in a hot-bed in spring; and when the plants are a few inches high, prick them out into separate small pots, giving water and occasional shade: afterwards manage them as other shrubby exotics of the green-house.

Cuttings of these sorts may also be struck by aid of the hot-bed, in spring or summer.

Hot-house Kinds.—They may be raised both from seed sown in pots, and plunged in a hot-bed; and by cuttings in spring or summer, planted in pots and plunged in any good hot-bed, or in the bark-bed of the stove, &c.

PHYTOLACCA, American Nightshade.

It furnishes principally herbaceous plants, one or two of which, hardy perennials, are retained as ornamental plants for the pleasure-garden; rising several feet high, adorned with large oblong and oval entire leaves; and clusters of pentapetalous flowers.

Class and order, Decandria Decagynia.

Characters.] CALIX, none. COROLLA, five roundish, concave, spreading, coloured, permanent, reflexed petals. STAMINA, ten,

eight, or twenty filaments, in different species, and roundish antheræ. PISTILLIUM, an orbicular depressed germen, divided on the outside, and terminated by ten very short patent, reflexed styles, having simple permanent stigmas. PERICAPIUM, an orbicular; depressed, ten-furrowed, decemlocular, berry, having a single kidney-shaped seed in each cell.

There are four species, three herbaceous, and one shrubby; the most material of which are the two following herbaceous perennials.

¹PHYTOLACCA Decandria.

Decandrous Virginia Phytolacca, or Common American Nightshade.] Hath a very thick, fleshy, divided, deeply-penetrating root; upright, strong, herbaceous stems, dividing and branching six or seven feet high, covered with a purplish bark; garnished with large, oblong, entire leaves, placed irregularly; and at the joints and axillas of the stalks long pedunculi, sustaining each a large cluster of small decandrous and decagynous, purple flowers; succeeded by depressed ten-furrowed berries, ripening in autumn.

²PHYTOLACCA Octandria.

Octandrous Mexican Phytolacca.] Hath a fleshy root; upright, strong, herbaceous stem, dividing and branching two or three feet high; oval, spear-shaped, veined leaves, placed irregularly; and from the side of the branches long pedunculi, terminated by spikes of close-fitting, octandrous and octogynous, white flowers; succeeded by depressed, ten-furrowed berries, ripening in autumn.

Both these species flower in July and August, the flowers are numerous in each cluster and spike; each flower being composed of five permanent petals, &c. succeeded by berries, as described in the characters, furnishing plenty of ripe seed in favourable autumns.

The juice of the berries stain linen and paper of a fine purple colour, but is not lasting.

These plants are perennial in root, but annual in stalk, which rising in spring, decays at the approach of winter.

They may be employed as plants of ornament in any of the compartments of the pleasure garden, but principally in a dry situation, where they will abide in root many years, particularly the first sort, and shoot up new stalks every spring, and produce their flowers and fruit abundantly, and make a good appearance.

The

The first species, *Phytolacca Decandria*, is the sort the most commonly known and cultivated.

The propagation of both the species is by seed, sowed in spring, in any bed or border of light earth, in shallow drills half an inch deep; and when the plants are come up three or four inches high, plant them out in moist weather, either in nursery-rows till autumn, or at once into the places where they are to remain.

PINUS, Pine-tree, including the fir-tree, &c.

This genus comprises a grand collection of noble ever-green trees, and one deciduous kind, obtaining great height and magnitude, and of high value and worth, both for their beautiful growth to embellish ornamental plantations, and for their great utility as timber-trees. All of them closely garnished with small linear acerose leaves; and monoecious, amentaceous, apetalous flowers, succeeded in the females by a scaly conic seed-vessel, called a cone.

Class and order, *Monoecia Monadelphia*.

Characters.] CALIX, male and female flowers, separate on the same plant, having scaly calices, the males being collected into scaly bunches, and the females into an imbricated cone, composed of oblong, rigid, permanent scales, each containing two florets. COROLLA, no petals, each floret consisting only of the fructifications. STAMINA, many monadelphous filaments having erect antheræ. PISTILLUM, a very small germen, awl-shaped style, and simple stigma. PERICARPIUM, none, the seeds are lodged in the calycinal scaly cone, each seed is an oblong-oval nut, furnished with a membranaceous wing.

To this genus of *Pinus*, Linnæus has added *Abies*, the Fir-tree, *Cedrus* and *Laris*, the Cedar of Lebanon and Larch-tree; which former botanists considered as so many distinct genera; but their generic characters being the same in every respect as the *Pinus*, they are now all ranged as species only of that genus: all the species of which, except the *Larix*, are ever-greens, and rise to a vast height, some above an hundred feet, with perfectly straight stems; branching all around almost to the very bottom, mostly in circular tiers or courses, at distances one above another, spreading regularly like rays, in a somewhat horizontal position, shortening gradually towards the top so as to give the head a

conical form; which being very closely garnished with linear, or very narrow acerose leaves; they appear with a beautiful majestic grandeur, and are all so very hardy, that they prosper in almost any soil and situation; and are exceedingly well adapted both for ornamental and profitable plantations.

There are about ten or twelve distinct species: those commonly called Pine-trees, are very distinguishable by sight from the Firs, and both of these from the Cedar of Lebanon and Larch-tree. The leaves of the former (Pine-tree) come out by two, three, or five from the same point and sheath: those of the Firs come out singly, and the Cedar of Lebanon and Larch arise in bunches from the same point, those of each bunch spread out every way.

Pine Kinds; having two, three or five Leaves in each Sheath.

There are about five or six species of these kinds, with some varieties; all hardy ever-green trees.

¹PINUS *Sylvestris*.

Wild Pine-tree, or Scotch Pine, most commonly called Scotch Fir.] Rises with an upright, perfectly straight stem, from about fifty to seventy feet high, or more, branching regularly all around; short, smooth, dark-green leaves, two in each sheath, but the primordial, or first leaves, come singly; and short pyramidal acute cones.

It grows wild in gravelly woods, in many of the northern parts of Europe, and in great plenty in the Highlands of Scotland: hence the name *Scotch Pine*, &c.

There are vast plantations of this valuable tree in most parts of Scotland, where they beautifully enrich gentlemen's estates; in which we may see them prosper in all exposures and soils, even on mountains and rocks, as well as in low moist ground; so may be cultivated to great advantage in any situation, and in places where many other trees, &c. would not thrive.

The timber of this tree is the common red, or yellow deal, of great value for all kinds of buildings.

Variety.] ²PINUS *Pinaster*.

Pinaster, or Foreign Wild Pine.] Rises with an upright, straight stem, from fifty to sixty or seventy feet high, sending out large, horizontally spreading, yellowish branches, irregularly; very long, smooth leaves, two in each

each sheath, but the primordial ones singly; and very long, pyramidal, acute cones.

³PINUS *Pinea*.

Pinea, or Italian Stone Pine.] Rises with an upright, straight stem, fifty or sixty feet high, having a roughish bark; very long, sea-green leaves, two in each sheath, with the primordial ones singly and ciliated; and thick, roundish, turbinate, close cones; having large, eatable kernels.

It is a native of Italy and Spain, where the kernels of the cone are in much esteem for eating, and are very wholesome, and good for colds and consumptions.

⁴PINUS *Strobus*.

Strobus Pine-tree, commonly called Weymouth Pine.] Rises with an upright very straight stem, an hundred feet high, or more, branching widely around, having a very smooth bark; long, slender, dusky-green leaves, by fives in each sheath; and long, slender, loose cones.

It is a native of North America, and first cultivated here on Lord Weymouth's estate, hence the name, *Weymouth Pine*. It is a tree of admirable beauty, and the prodigious height and magnitude which it attains, renders it of great value for its timber, and makes the most excellent masts for ships.

⁵PINUS *Tæda*.

Tæda, or Torch Pine, or Three-leaved Virginia Swamp Pine.] Rises with an upright stem to a great height; having very long, slender leaves, by three in each sheath; and large, long, loose cones.

It grows naturally in low swampy grounds in Virginia and Canada.

⁶PINUS *Cembra*.

Cembra, or Mountain Siberian Pine.] Rises with an upright straight stem, forty or fifty feet high; having long, slender, very smooth, light-green leaves, five in a sheath; and large close cones.

The above six sorts are the principal species of the Pine kind, but there are several varieties that belong to one or other of them, and are distinguished in the nurseries by the following names and descriptions.

Frankincense three-leaved American Pine—Virginia three-leaved, prickly-coned Pine—Virginia cluster-coned Pine—Mugho two and three-leaved mountain Pine—Jersey two-leaved prickly-coned Pine—Aleppo spreading-branched, two-leaved Pine—dwarf two-leaved American Pine.

Fir Kinds (Abies) having Solitary or Singly-placed Leaves.

There are about six species of these sorts, with some varieties; all hardy ever-green trees.

PINUS *Abies*.

Abies, or Common Fir-tree, commonly called Norway Spruce Fir.] Rises with an upright stem, to a great height, branchy to the bottom; solitary, narrow, awl-shaped, sharp-pointed, smooth, dark-green leaves, standing two ways; and large cones, six or eight inches long, hanging downward.

Variety.] Long-coned Cornish Fir, having longer leaves, and cones eight or ten inches long.

They grow naturally in Norway, and other northern parts of Europe, where they are commonly denominated Pitch-firs, because in those countries great quantities of pitch, &c. is extracted from them; their timber is the white deal, so greatly esteemed by the joiners.

⁸PINUS *Canadensis*.

Canada Spruce Fir.] Rises with an upright, straight stem, to a great height, branching from bottom to top; solitary, very narrow, shortish, obtuse-pointed, dark-green leaves; and small close cones an inch long.

Varieties.] Canada white spruce—red spruce—and black spruce Fir; differing from each other principally in the colour of the cones. These are all natives of North America.

⁹PINUS *Picea*.

Picea, or Pitch-tree, commonly called Silver Fir.] Rises with an upright very straight stem, sixty or seventy feet high, or more, branching thinly, having a smooth bark; solitary flat leaves, emarginated at top, marked with two silvery white lines underneath; and has very long erect cones.

It grows naturally in the Alps, Germany, and in the Highlands of Scotland, and is remarkable for affording plenty of turpentine, &c.

¹⁰PINUS *Balsamea*.

Balsamea, or Balm of Gilead Fir.] Rises with an upright; straight stem, very branchy almost to the bottom; closely garnished with solitary, flat, obtuse leaves, slightly emarginated at the top, of a dark-green above, and marked with whitish lines underneath; and small roundish cones.

Variety.] With variegated leaves.

This tree and variety are natives of North America; they are remarkable for their balsamic

famic aromatic nature ; the buds and leaves being remarkably fragrant, and any part of the tree being cut or broken, it will emit abundance of fine balsamic juice, or turpentine. Both the varieties assume a beautiful growth, and have great merit for all ornamental plantations.

The following is a variety of some of the Spruce kinds.

American Hemlock Spruce Fir.—Rises with an upright stem of moderate height, branching thinly, narrow obtuse leaves, ranged two ways ; and roundish cones.

Cedar of Lebanon, and Larch Kinds, having Leaves in Bunches.

There are only two species of those kinds, one a celebrated ever-green tree, of great antiquity ; the other a beautiful deciduous tree : both of them valuable for ornament, and for timber plantations.

¹¹PINUS Cedrus.

Cedrus, or Cedar of Lebanon.] Rises with an upright trunk, obtaining considerable height and magnitude, branching horizontally around to a great width ; closely garnished with narrow, acute, stiff leaves, in bunches from the same point ; and largish, thick, close cones.

It is a native of Mount Libanus in Syria ; is very hardy, and prospers here in almost any soil and situation.

This famous and curious tree is the lofty and spreading Cedar so greatly celebrated in scripture ; to which many beautiful allusions and comparisons are made ; and is more certainly a tree of singular grandeur, after having arrived to some considerable growth, as it spreads its horizontal branches in the most agreeable form, very widely around ; which agrees with the allusion of the Psalmist when saying—*She spreadeth her branches like the cedar-tree.* Mount Libanus seems to be the chief place of its natural or original residence ; where, by accounts of travellers, there are still a few old trees of prodigious magnitude remaining ; but the cones having been dispersed into many different countries, they have raised large plantations of the trees, and in some places are arrived to a considerable size ; though in England there are only at present here and there a tree, that is of any considerable growth : they, however, are now raised abundantly in all the public nurseries ; and of late years numbers of the trees have been planted on many estates, for they will prosper in almost any soil and exposure, and have great merit

for all ornamental plantations ; likewise as timber-trees : the wood of which being of superior value.

There are said to be some large trees still remaining upon Mount Lebanon, whose trunks are thirteen yards in circumference, and the branches spreading forty paces every way around.

It is said the timber of this wonderful tree is proof against all putrefaction, and that it will continue sound two thousand years : it was greatly used in the buildings of Solomon's temple, and other sacred structures of antiquity.

¹²PINUS Larix,—(Deciduous.)

Larix, Larch-tree, or Deciduous Pine.] Rises with an upright, straight, whitish stem, to a great height, sending out long, slender, pendulous branches ; long, fine, obtuse-pointed, light-green leaves, in bunches from the same point, spreading open above ; and with flowers of different colours in the varieties ; succeeded by small, close, acute cones, an inch long.

It is a native of the Alps, Switzerland, and Italy, &c. which, though deciduous, is a tree of beautiful growth.

Varieties.] Common red Larch-tree, having reddish flowers and cones—white Larch-tree—black American Larch-tree—horizontal Larch-tree—dwarf Larch-tree.

All these twelve species of *Pinus* flower in spring, principally in April and May, but make very little show : the flowers are universally monoecious, apetalous, and amentaceous, with the males collected into conic branches, and the females into close cones, which gradually grow into real cones that produce the seeds, which will be ready for gathering in November.

All these twelve species are trees of the first magnitude and beauty ; eleven of which are ever-greens, the twelfth is deciduous, and are all of hardy nature, so as to prosper in almost any soil and situation ; having all great merit both to enrich our ornamental plantations, and most of them also as timber-trees ; and for either purpose they may be employed in any exposure in gardens, parks, or fields, or either in plains, or the sides or tops of hills, and in woods and clumps of all sorts ; the Scotch Pine in particular is the hardiest of all the sorts ; scarcely any country soil or situation comes amiss to it, even on the tops of mountains and rocks where there is hardly any earth, and only crevices for their roots to strike into ; in short, all the species of other *Pinus* in general possess nearly the same degree of hardiness ;

hardiness; for though they may make the greatest progress in deep and somewhat moist soils, yet they will also thrive tolerably both in clayey and sandy soils, as well as in a gravelly, stony, and stony ground; so that all the sorts may be employed almost any where both for ornamental or profitable plantations: remarking, however, that the better the soil is, the greater progress they will probably make in their growth.

Therefore these fine trees are highly proper for plantations of all kinds, both for pleasure and profit; and will greatly beautify and enliven the scene, as well as cause great variety among themselves, by the difference of their leaves and cones; and as all the sorts produce cones abundantly, furnished with plenty of seed, they may be easily raised in any quantity in the common ground. See their *Propagation*.

It is affirmed that plantations of these trees, besides their being beautiful to behold when growing, and profitable as timber-trees, they render the air exceedingly wholesome by their balsamic and aromatic exhalations, which they emit, and diffuse widely around.

They are all very swift growers, as after being a few years old, they often shoot two or three feet in height in the course of one season, mostly performing the whole shoot by Midsummer; and always aspire with one erect firm shoot in the middle, forming the stem, which at the termination of every year's shoot, sends out a tier of branches circularly.

Considered as forest or timber-trees, they are of great value, as their timber is the principal wood used in our buildings, &c. but the principal sorts for timber-trees are, the Scotch Pine—Pineaster—Weymouth Pine—Swamp Pine—Stone Pine—Spruce Fir, and varieties—and Silver Fir. The timber of these sorts is what we commonly call deal, and is of universal utility, particularly for all kinds of buildings, and innumerable other uses: they are also of great value in ship-building, and are most excellent for masts, in which they exceed all other trees yet known, particularly the Scotch Pine, Pineaster, and Weymouth Pine; but the latter most of all, as it often grows to above a hundred feet high, with proportionable substance.

The Cedar of Lebanon and Larch-tree may also be employed in our plantations of timber-trees, for they will arrive to a great size in this country, as is evident by some old trees now in some gardens, &c.

Most of these trees are resinous or gummy: of an agreeable aromatic smell, but bitter taste.

It is from the Pine and Fir kinds that pitch, turpentine, and rosin are procured; being extracted from the growing trees, in the countries where they abound, and of which is made a very considerable merchandize.

Most of these trees possess also very salutary medical properties. A decoction in milk of the seeds of Pineaster, or the extremity of the young branches pulled in spring, is said, with a proper regimen, to cure the most confirmed inveterate scurvy: the branches of the common Spruce Fir, are used by the Americans for making their spruce-beer.

All the species of these trees are propagated in great abundance in the public nurseries, where they may be purchased in any quantity at moderate rates, or may be easily raised from seed, as directed under the article of their *Propagation*.

It is advisable to plant out all these trees when they are young, not more than three or four feet high, or if younger the better; as they will root more freely, and make much greater progress.

The best season for planting all these kinds of trees is autumn or spring, i. e. September, October, and November, for the autumnal planting, and February and March for the spring; tho' they may also all be removed with tolerable success any time in open weather in winter, from September till March; but those transplanted early in autumn will generally have taken root before winter comes on, and begin to establish themselves more firmly before the drought of the ensuing summer.

When intended to have ornamental plantations of these trees, they may be planted both in clumps and in continued plantations, sometimes by themselves, and some in assemblage with other trees of similar growth, stationing the ever-greens principally with those of that tribe; though, for the general part, they appear to the best advantage when disposed by themselves in various elegant clumps, and running plantations: observing to have a proper intermixture of the different sorts, and allow a proper distance between the trees, that they may have room to spread their heads around distinctly, and be branchy quite to the bottom. Some trees of different sorts may also be disposed as single objects, in lawns, parks, and other spacious openings.

But when designed to have any planted for timber-trees, they should always be planted in continued plantations, and set pretty close, so as to draw them more effectually up in height; for it is the length as well as the substance of this timber that greatly enhances its value; therefore they may be planted only four or five feet asunder, and in seven years some of the weakest may be thinned out, and in two or three years after the thinning may be repeated; and so continue gradually thinning out the underlings, which will do for poles, spars, &c. and thus should these plantations be thinned occasionally till the principal trees designed for standing are arrived at maturity, whereby they will aspire to a prodigious height, with stems as straight as an arrow.

After making any plantation of these trees either for pleasure or profit, no farther trouble or expence is necessary, than keeping down large weeds, &c. whilst the plantation is young, and fencing against cattle, for they do not require any trimming, as none of the branches should by any means be lopped, which would not only spoil the beauty of the trees, but would retard their growth in proportion.

Propagation and General Culture of all the Sorts.

All the species of *Pinus* and varieties in general are propagated only by seed, which will grow freely in the common ground, either in beds or borders of light earth, or in pots or boxes of the like soil, in order for moving occasionally to different situations at different seasons; and the season for sowing all the sorts is in March and April.

Most of the sorts produce cones abundantly in our gardens and plantations, ripening in autumn and winter, containing plenty of seeds; observing to gather the cones in the proper time. All those in particular that are of a loose nature ought to be gathered early in winter, otherwise they are apt to open and disseminate their seeds; but those that are compact and firm may hang longer, and be gathered any time about the middle or end of winter, or towards spring. The cones of most of the sorts are also sent us from the different countries where the trees abound; and are sold at all the public nurseries and seed-dealers at moderate rates; either the cones entire, or the seeds cleared from the cones: the method of taken out the seeds is as directed below.

It must be observed of getting the seed out of the cones, that as the cones are composed of numerous hard bony scales, very closely placed, having the seeds lodged between them; and that sometimes the scales being almost united, especially in some of the Pine kinds, Cedar of Lebanon, &c. and often so closely involve the seeds as they cannot be dislodged without violence of breaking or splitting the cones open with an instrument; though those of many of the sorts will open readily by exposing them before a fire, or to the Midsummer sun, when the heat will cause the scales to open gradually, so as the seeds will easily shake out; but by waiting till summer for the heat of the sun to open the cones, we lose a year in the time of sowing, therefore having procured a quantity of the cones in autumn or winter, they may be laid before a moderate fire, at some reasonable distance, so as not to scorch the seeds: thus the scales will open, and the seeds may easily be beaten out of their cells; though some sorts, particularly the Stone pine and Cedar of Lebanon cones are so close and hard that the seeds cannot be dislodged without violence, as above observed, and is generally effected either by breaking them with a vice, or by boring a hole with an instrument up the middle of each cone, then having an wooden or iron peg of a proper size, drive it through the hole, which will split and divide the cone so as the scales may be easily removed and the seeds taken out ready for sowing.

With regard to the proper soil and situation in which to sow these seeds, almost any common light ground in the nursery will do, but give preference, where practicable, to a light sandy loamy soil; and as to situation or exposure it may either be any of the open quarters of the seminary, or in a somewhat shady border, in which they generally rise stronger than in a full exposure, unless the beds, &c. are shaded occasionally in hot dry weather in sunny days when the plants begin to come up.

The best season for sowing all the sorts is March, but not later than the beginning of April.

Having, therefore, a proper quantity of seed ready; and the ground prepared by proper digging, and formed into one or more beds, three or four feet wide; take advantage of a dry day, and sow the seeds, scattering them moderately thick all over the surface of the beds, and cover them half an inch deep with finely-broken light mould; or where there

there are only a small quantity to be raised, the seeds may be sowed in large pots, or boxes of light sandy loam, covering them the above depth; though this practice is more particularly necessary for the Cedar of Lebanon, in order to move the plants into the shade in summer, and to a sunny warm exposure in winter; but for the sake of which convenience some sow most of the sorts in pots or boxes; and some, in order to forward them as much as possible, sow them in pots, and plunge them in a moderate hot-bed just to bring up the plants. They, however, will all succeed tolerably in the full ground, especially all the Pine, Fir, and Larch kinds; and most of the sorts will come up in six or seven weeks after sowing.

Having, however, sowed the seed, the following little attendances are necessary in respect to the care of the seed-bed and young seedling plants. In the first place observe, that as these seedlings generally rise out of the ground with the husk of the seed on their tops, which being once observed by the birds, they will attack them from all parts, and if not prevented, will pull them up as fast as they appear above ground; it is therefore advisable to defend them at this time, by spreading nets over the beds, &c. upon proper support, to remain until the plants are all fairly come up, and have thrust their husks off their heads. In the next place, it will be of advantage at this time to give occasional slight shade of mats, in hot sunny days, to those in a full exposure. Give also occasional very moderate waterings in dry weather; and keep them clear from weeds all summer. With the above care the seedlings will advance and form little slender plants by autumn following, though some probably will only be furnished with a few leaves at top, and just formed buds in the centre, ready to push next spring; others, more forward will likely have made a short shoot by autumn: observing they are to remain in the seed-bed till a year old, they are hardy enough to stand the winter without any covering, except the Cedar of Lebanon, which if the weather proves severe, it may be proper to shelter occasionally either with mats or a hot-bed frame: but all the others generally stand the severest frost unhurt; and by spring following, all the sorts should be pricked out into nursery-beds.

In spring following, therefore, the seedlings being one year old, they should in ge-

neral be pricked out from the seed-bed into nursery-beds, and March or beginning of April is the proper time, observing to form beds for their reception four feet wide; then taking up the seedlings out of the seed-bed with all their roots as entire as possible, prick them in the new-prepared beds, in rows six inches asunder; here let them have two years growth, when by the end of the second summer they will have shot six inches, or more; then in spring after it is advisable to transplant them in wider rows, also in the nursery; observing in this second removal to set them in rows two feet asunder, and one at least in the lines, as they are to remain here till of a proper growth for final transplantation; they will here shoot six or eight inches more in height the ensuing summer; and in another year they will push with much greater vigour, probably make a shoot of half a yard or two feet long; so that when about four or five years old they will be about a yard high; and if they stand a year or two longer they will be proportionably taller, and of full size for final transplantation.

Though it is most advisable to transplant all these sorts of trees finally when not above two or three feet high, as they generally take root sooner, and set to growing more freely than trees of larger growth; for although most of the sorts may be transplanted when six or eight feet high, yet trees of two feet most commonly make the greatest progress.

However, when there is a necessity of retaining these trees longer in the nursery, it will be of advantage to transplant them every two years, whereby the roots will be kept shorter, and throw out a great many fibres, so as to admit of being removed with safety, for without the precaution of removal, trees of some years standing would extend their main roots to a great distance, and be unfurnished with fibres, in which case large trees would be very liable to fail; but in the other method, trees of six or eight feet stature are sometimes removed with tolerable success; though the transplantation of such large trees of these kinds should only be practised where an immediate shew is required in ornamental plantations.

But I should advise, for the general part, that most of the sorts, the Pine and Fir kinds in particular, have their final transplantation when not more than two or three feet high, as before hinted, especially where any considerable

derable plantation is intended, more particularly if designed as forest-trees. I have, indeed, assisted in planting many thousand of the Scotch Pine, and others, when little more than a foot high, on the sides of hills and waste grounds, without any previous preparation of the soil, than just making an aperture, or hole for each plant, and frequently only making a slit with the spade for the reception of each, leaving them to shift for themselves, and securing the boundaries of the ground against cattle: most of them have succeeded; though, in general, plants about two feet or a yard high, are an eligible size for any plantation.

The season for making plantations of these sorts is autumn or spring, or even in winter during mild weather, as already noticed.

In taking up all these kind of trees for any plantation, observe with particular care to raise them with all the roots as entire as possible: preserve also their tops perfectly entire, likewise all their branches, and in that state let them be planted; only previously with your knife trim any broken or very straggling part of the root.

With regard to the distribution, or arrangement in the different plantations, and mode of planting, they are as follow—Those designed for embellishing the shrubbery compartments, and for ornamental plantations in general, may be disposed both in assemblage with other trees, and to form clumps, and continued plantations occasionally of themselves. But those intended as forest-trees should generally be disposed alone in considerable plantations: and, as to the method of planting them, it is the same as for other hardy trees, see PLANTING: observing however, where large plantations in out-grounds are intended either for pleasure or profit, there will not be any great necessity for a previous preparation of the soil, with respect to digging or ploughing, only just to dig a hole for each tree: the same rule may also be observed in planting clumps of them in lawns, parks, and other grass-ground. Observing, that those designed principally for ornament, should be disposed at such distances as their branches may extend freely every way, for the beautiful display of the head is a great merit in these trees in pleasurable plantations; but those intended for timber plantations, may be planted only four or five feet distance, in order that they may draw one

another up straight and tall more expeditiously, and to admit of a gradual thinning after a few years growth, for poles, &c. as already observed.

After having their final transplantation, they require but very little more trouble, only observing to clear them, while young, from overbearing weeds; and if any large trees, five or six feet high, or upwards, are planted, it is proper to support each tree with a stake, to secure them against the power of tempestuous winds, till firmly rooted.

Let all the sorts take their own natural growth; being careful to preserve their tops perfectly entire, to shoot up as fast as possible; suffering them also to branch out in their own way; for no pruning is wanted, unless the lowermost tier of branches in any particular trees should be thought too low and straggling, when these may be occasionally trimmed, cutting close to the stem; but prune no further, for it should be very sparingly practised to these resinous trees, as lopping the branches contributes to retard their growth, as well as impair their beauty. Indeed in large forest plantations, where the trees are arrived to a large growth, it is customary to lop their lower branches gradually for faggots, according as they begin to decay, for where these trees stand close, the upper branches generally kill those below, so that the lower tiers decay gradually and successively one tier after another; and in which case, these decaying lower branches may be lopped by degrees in winter.

When the plantations designed for timber-trees have had from eight to ten or twelve years growth, it may be proper to begin to thin them, observing the rules before laid down: those thinned out will serve for many smaller purposes, being careful in thinning to leave a sufficiency of the finest plants standing at proper distances, to grow up for timber.

PISTACIA, Pistachia-nut, or Turpentine-tree.

This genus consists of the tree and shrub-kind, furnishing hardy deciduous trees for the shrubbery, and ever-green shrubs for the green-house, all of them of upright growth, rising twenty or thirty feet high, garnished with pinnated and trifoliate leaves, and dioecious, amentaceous, apetalous flowers, succeeded by drupaceous berries, furnished with oval nuts; which in some species are eatable.

Class

Class and Order, *Dioecia Tetrandria*.

Characters.] CALIX, male and female flowers on distinct trees, the males collected into loose, sparsely amentums, composed of small scales, each having one floret, furnished with a very small, five-parted perianthium; and the females in clusters, with small trifid cups. COROLLA, small florets without petals. STAMINA, four very small filaments, having large, oval, tetragonous, erect, petalous antheræ. PISTILLUM, an oval germen, three reflexed styles, with thick hispid stigmas. PERICARPIUM, an oval berry-like drupe, having an oval smooth nut.

There are five species, four of which are hardy shrubs, mostly deciduous; the other is a tender ever-green for the green-house.

Hardy Kinds.

These kinds, however, though denominated hardy, are rather tender whilst young, at least those raised from seed, requiring shelter of a green-house or garden-frame, in winter, till four or five years old, and are become a little woody.

¹PISTACIA Vera.

True Pistachia-tree.] Rises with an upright stem, branching twenty or thirty feet high, covered with a rustily cracked bark, but the younger branches smooth; large pinnated leaves, of two or three pair of oval recurved lobes, terminated by an odd one; and from the sides of the branches small greenish flowers in amentums and bunches, succeeded in the female trees by clusters of oval fruit, containing large eatable nuts.

It is a native of Persia, Arabia, and Syria, from whence the nuts are brought annually, for they rarely ripen here in our gardens, and are sold in the shops by the name of Pistachia-nuts.

PISTACIA Terebinthus.

Terebinthus, or Turpentine-tree.] Rises with an upright branchy stem, about thirty feet high, having a dark bark full of cracks; pinnated, dark-green, alternate leaves, of three or four pair of oval-spear-shaped lobes, terminated by an odd one; and small greenish flowers.

It grows naturally in Italy and Spain, and from its trunk flows the true Turpentine, but that of some of our Pine-trees is commonly substituted.

²PISTACIA Trifolia.

Trifoliate Pistachia-tree.] Rises with an upright branchy stem, between twenty and

thirty feet high, having a rough brown bark; trifoliate or three-lobed, dark-green leaves; and small greenish flowers.

³PISTACIA Narbonensis.

Narbonne Turpentine-tree.] Rises with an upright branchy stem, about twenty feet high, having a whitish bark; pinnated leaves, mostly of three or five roundish lobes; and small greenish flowers.

The first sort is the hardiest of all the above four species, and the third and fourth are the tenderest, and are often kept here in the green-house collections, also sometimes the common Turpentine-tree; but they may all be gradually hardened to bear the full air the year round.

Green-house Kinds.

⁴PISTACIA Lentiscus.

Lentiscus, or Mastick-tree.] Rises with an upright branchy stem, fifteen or twenty feet high, having a greyish bark; abruptly pinnated leaves, of three or four pair of spear-shaped lobes, not terminated by an odd one; and small greenish flowers.

From this species and variety is collected the Mastick of the shops.

Variety.] Narrow-leaved Lentiscus.

All the above five species of *Pistacia* flower generally in April; they are universally dioecious, or male and female upon separate trees; are small and without petals, with the males collected into amentums, and the females in bunches, mostly of a greenish colour, so make no show; and those of the females are succeeded by clusters of fruit, ripening to a blue or blackish colour, inclosing the nuts, but these never ripen in England.

With respect to the merit of those trees in our gardens, observe as follows:

The first four species are proper to increase the collection in curious shrubberies, observing as they are of somewhat tender quality, should have occasional shelter from frost whilst young, so should be kept in pots till three or four years old, so as they have obtained a little strength, and become woody, they may be turned out into the open ground, in a dry warm situation; and may also retain some in pots, to have occasional shelter among the green-house plants in severe winters, more particularly the *Trifoliate* and *Narbonne* kinds; which two sorts, if sheltered in winter, will often retain their leaves great part of the year; and being more tender than the first and second, they are in many gardens retained as green-house plants. All these four sorts, however

however denominated hardy, may be gradually hardened to bear the full air the year round, as aforesaid.

The fifth sort, *Lentiscus*, is a pretty evergreen, of a tenderer nature than the other four, so must have shelter, all winter, of a green-house; in which collection it highly merits culture, as it effects a distinguishable variety at all seasons of the year.

Their Propagation, &c.

The propagation of all the five species is principally by seed; and some sorts also by layers.

By Seed.—The nuts are the seed, which of all the sorts are procured from abroad annually, and may be obtained at most of the nurseries, &c. observing they all require the aid of a hot-bed. Let them be sowed early in spring, in pots of light earth, half an inch deep, and plunge the pots in a hot-bed, just to bring up the plants: when this is effected, be careful to admit a large portion of fresh air daily and by degrees harden them to it fully in June, giving frequent refreshments of water all the summer; and in autumn remove the pots to the shelter of a hot-bed frame, or a green-house, to remain all winter; then in spring following plant them out into separate small pots, which if directly plunged in a moderate hot-bed it will greatly facilitate their rooting, and set them forward; but when they begin to shoot, harden them to the full air, still continuing a proper supply of watering; and in autumn remove them again to a frame or green-house, for the winter; which care must be repeated to all the sorts till they are three or four years old, as aforesaid; shifting them occasionally into larger pots. After this, most of the four hardy kinds may be turned out into the shrubby compartments to remain; but the *Lentiscus* must still be continued in pots to have shelter in winter with other green-house exotics.

By Layers.—Most of the sorts may be tried by this method; but the *Lentiscus*, in particular, is very commonly propagated by layers. Chuse the most conveniently situated young shoots, which lay in spring by common laying, and they will be mostly well rooted by the following autumn; when they should be taken up and potted separately, and managed as the seedlings.

PISTILLUM, the Pistil, or Pointal of the flower, or female organ of the generation of

plants, rising in the centre of the flower like a column, consisting of the germen, style, and stigma.

1. The *Germen* forms the base of the *Pistillum*, and is the seed-bud, or rudiments of the seed-vessel, or fruit, and supports the style, elevated like a pillar in the middle of the flower. See GERMEN.

2. The Style (*Stylus*) stands upon the summit of the germen, elevated like a column, and corresponds to the *vagina* in animals, being generally somewhat hollow like a tube, tho' the tubular parts are often so fine as to be scarcely perceptible, serving to transmit the effluvia of the fecundating dust, or *Pollen*, through into the heart of the germen, or seed-bud, for the purpose of impregnating the seeds, and is terminated by the stigma. See STYLUS.

3. The Stigma is the summit or head of the style, appearing frequently like a knob or head, and when there is no style, it adheres to the summit of the germen; and its use is to receive the male-dust from the antheræ; thence transmitting its vapour through the *vagina*, or style, aforesaid, into the heart of the seed-bud, for the purpose of impregnation. See STIGMA.

Each of the above parts of the *Pistillum* is more particularly explained under its respective head.

PISUM, the Pea.

This genus consists wholly of hardy herbaceous plants, one species of which, the *common Pea*, an annual, is the parent of all the numerous varieties of Peas cultivated in our gardens and fields for common use, the merits of which, as esculents, are universally known; all of which rise with long, slender, cirrhose climbing stalks; garnished with cirrhose-pinnated leaves, and papilionaceous flowers; succeeded by that sort of seed-vessel called a legumen, or pod, filled with Peas, the eatable part of the plant.

Class and Order, *Diadelphia Decandria*.

Characters.] CALIX, is monophyllous, acutely five-parted and permanent. COROLLA, is papilionaceous, consisting of a broad heart-shaped, reflexed, indented standard, ending with a point; two short, roundish, connivent wings, and a shorter, compressed, semi-lunulated keel. STAMINA, ten diadelphous filaments, crowned by a roundish antheræ. PISTILLUM, an oblong compressed germen, a triangular, rising, membranaceous style, and oblong hairy stigma. PERICARPIUM, a large, long, bivalvular pod, ending in

in a point, containing one row of roundish seeds or Peas.

The principal distinction between this genus and *Lathyrus*, (Everlasting Pea, &c.) is, the style of this is triangular, and that of the *Lathyrus* is plane. See *LATHYRUS*.

There are four species of this genus; two only of which have merit for our purpose; though there is only one species considered as an esculent for general culture, which is the *Common Cultivated Pea*, comprising, however, numerous varieties; for all the sorts of garden and field Peas are varieties only of one species; but whether the common white Pea of our gardens, or the grey field Pea be the original kind, is uncertain. The other species alluded to is considered principally as a flowery plant belonging to the tribe of hardy annuals.

Cultivated Kinds.

Pisum Sativum.

Common Cultivated Pea.] Rises with long, slender, trailing stalks, by clasping upon support, from two to six or eight feet high; pinnated, cirrhose leaves, of about three pair of lobes, terminated by cirrhi, or tendrils, and have taper foot-stalks, with roundish, indented stipula below; and at the axillas long pedunculi supporting many flowers, &c.

Varieties.] Common white Pea—common grey field Pea; each of which comprising many varieties.

Each of these two principal varieties of this species, *Pisum Sativum*, comprise numerous others, particularly the white sort; and new ones are obtained almost every year, in one place or other, differing from one another in some little particular, either in their growth, manner, and time of blossoming and bearing, size and form of the pods and peas, together with their quality for eating; and several other little properties or singularities, all of which are accidental varieties, rising from one another; for suppose we were to cultivate only any one of the varieties, we by observation will find plants varying from the original sort, sometimes probably for the better, and sometimes worse; but the first only is to be regarded; and it is by observing this, that curious persons have increased the valuable varieties, when by examining their crops, find one plant very different from all the rest, or any other known sort, either by its blossoming and bearing earlier, or some other valuable singularity,

carefully mark it, and preserve all its produce for seed; which being sowed separately for two or three years, or till having multiplied them sufficiently to be distributed, they are sent into the world as a new sort, bearing the name probably of the place, or person who first obtained them, such as the Charlton Pea, &c. Thus the different varieties of Peas are obtained, and each respective variety multiplied for public supply: some of which varieties differ very materially from one another, either by their early bearing, or by their larger growth, or the like, though some reputed varieties differ so immaterially that the difference is hardly distinguishable. And it is to be remarked of all these acquired varieties, that although some are tolerably permanent, yet without proper care in saving the seed of each sort separate, they will all gradually degenerate to one another, or to the common white, or grey kind; so that it would in a manner be impossible to pretend to enumerate all the varieties of Peas, or to give any particular description of the different sorts; therefore we shall only exhibit a list of the principal varieties that are at present the most commonly known; which, though pretty many, there are not above five or six that have merit for general culture; some of which are moderate growers, and early bearers, commonly called Hotspurs; others are large growers, and come later into bearing.

Hotspurs, or smaller forward Kinds.] Early Charlton hotspur Pea—early golden hotspur, an improved variety of the Charlton kind—Nicholas earliest hotspur, an improvement of the golden sort—Masters hotspur Pea—Reading long hotspur Pea—dwarf hotspur Pea: with several other reputed varieties of less note, that hardly differ in any thing from the above sorts.

All the above are moderate growers, rising upon sticks only, three or four feet high: and the dwarf Pea scarcely half so much: they are all excellent bearers, producing moderate sized well filled pods; but the first four sorts differ very little from one another, only in some bearing a little earlier than others: the golden kinds are the present earliest bearers, and in the most esteem for the forward crops, though any of the hotspur sorts are proper both for the early and first general crops, or in short, for the principal crops during the whole pea-season, for they are rather sweeter eating Peas than the larger kinds: the Reading hotspurs in particular have great merit to make

however denominated hardy, may be gradually hardened to bear the full air the year round, as aforesaid.

The fifth sort, *Lentiscus*, is a pretty evergreen, of a tenderer nature than the other four, so must have shelter, all winter, of a green-house; in which collection it highly merits culture, as it effects a distinguishable variety at all seasons of the year.

Their Propagation, &c.

The propagation of all the five species is principally by seed; and some sorts also by layers.

By Seed.—The nuts are the seed, which of all the sorts are procured from abroad annually, and may be obtained at most of the nurseries, &c. observing they all require the aid of a hot-bed. Let them be sowed early in spring, in pots of light earth, half an inch deep, and plunge the pots in a hot-bed, just to bring up the plants: when this is effected, be careful to admit a large portion of fresh air daily and by degrees harden them to it fully in June, giving frequent refreshments of water all the summer; and in autumn remove the pots to the shelter of a hot-bed frame, or a green-house, to remain all winter; then in spring following plant them out into separate small pots, which if directly plunged in a moderate hot-bed it will greatly facilitate their rooting, and set them forward; but when they begin to shoot, harden them to the full air, still continuing a proper supply of watering; and in autumn remove them again to a frame or green-house, for the winter; which care must be repeated to all the sorts till they are three or four years old, as aforesaid; shifting them occasionally into larger pots. After this, most of the four hardy kinds may be turned out into the shrubbery compartments to remain; but the *Lentiscus* must still be continued in pots to have shelter in winter with other green-house exotics.

By Layers.—Most of the sorts may be tried by this method; but the *Lentiscus*, in particular, is very commonly propagated by layers. Chuse the most conveniently situated young shoots, which lay in spring by common laying, and they will be mostly well rooted by the following autumn; when they should be taken up and potted separately, and managed as the seedlings.

PISTILLUM, the Pistil, or Pointal of the flower, or female organ of the generation of

plants, rising in the centre of the flower like a column, consisting of the germen, style, and stigma.

1. The *Germen* forms the base of the *Pistillum*, and is the seed-bud, or rudiments of the seed-vessel, or fruit, and supports the style, elevated like a pillar in the middle of the flower. See GERMEN.

2. The Style (*Stylus*) stands upon the summit of the germen, elevated like a column, and corresponds to the *vagina* in animals, being generally somewhat hollow like a tube, tho' the tubular parts are often so fine as to be scarcely perceptible, serving to transmit the effluvia of the fecundating dust, or *Pollen*, through into the heart of the germen, or seed-bud, for the purpose of impregnating the seeds, and is terminated by the stigma. See STYLUS.

3. The Stigma is the summit or head of the style, appearing frequently like a knob or head, and when there is no style, it adheres to the summit of the germen; and its use is to receive the male-dust from the antheræ; thence transmitting its vapour through the *vagina*, or style, aforesaid, into the heart of the seed-bud, for the purpose of impregnation. See STIGMA.

Each of the above parts of the *Pistillum* is more particularly explained under its respective head.

PISUM, the Pea.

This genus consists wholly of hardy herbaceous plants, one species of which, the *common Pea*, an annual, is the parent of all the numerous varieties of Peas cultivated in our gardens and fields for common use, the merits of which, as esculents, are universally known; all of which rise with long, slender, cirrhose climbing stalks; garnished with cirrhose-pinnated leaves, and papilionaceous flowers; succeeded by that sort of seed-vessel called a legumen, or pod, filled with Peas, the eatable part of the plant.

Class and Order, *Diadelphia Decandria*.

Characters.] CALIX, is monophyllous, acutely five-parted and permanent. COROLLA, is papilionaceous, consisting of a broad heart-shaped, reflexed, indented standard, ending with a point; two short, roundish, connivent wings, and a shorter, compressed, semi-lunulated keel. STAMINA, ten diadelphous filaments, crowned by a roundish antheræ. PISTILLUM, an oblong compressed germen, a triangular, rising, membranaceous style, and oblong hairy stigma. PERICARPIUM, a large, long, bivalvular pod, ending

in a point, containing one row of roundish seeds or Peas.

The principal distinction between this genus and *Lathyrus*, (Everlasting Pea, &c.) is, the style of this is triangular, and that of the *Lathyrus* is plane. See LATHYRUS.

There are four species of this genus; two only of which have merit for our purpose; though there is only one species considered as an esculent for general culture, which is the *Common Cultivated Pea*, comprising, however, numerous varieties; for all the sorts of garden and field Peas are varieties only of one species; but whether the common white Pea of our gardens, or the grey field Pea be the original kind, is uncertain. The other species alluded to is considered principally as a flowery plant belonging to the tribe of hardy annuals.

Cultivated Kinds.

Pisum Sativum.

Common Cultivated Pea.] Rises with long, slender, trailing stalks, by claspers upon support, from two to six or eight feet high; pinnated, cirrhole leaves, of about three pair of lobes, terminated by cirrhi, or tendrils, and have taper foot-stalks, with roundish, indented stipula below; and at the axillas long pedunculi supporting many flowers, &c.

Varieties.] Common white Pea—common grey field Pea; each of which comprising many varieties.

Each of these two principal varieties of this species, *Pisum Sativum*, comprise numerous others, particularly the white sort; and new ones are obtained almost every year, in one place or other, differing from one another in some little particular, either in their growth, manner, and time of blossoming and bearing, size and form of the pods and peas, together with their quality for eating; and several other little properties or singularities, all of which are accidental varieties, rising from one another; for suppose we were to cultivate only any one of the varieties, we by observation will find plants varying from the original sort, sometimes probably for the better, and sometimes worse; but the first only is to be regarded; and it is by observing this, that curious persons have increased the valuable varieties, when by examining their crops, find one plant very different from all the rest, or any other known sort, either by its blossoming and bearing earlier, or some other valuable singularity,

carefully mark it, and preserve all its produce for seed; which being sowed separately for two or three years, or till having multiplied them sufficiently to be distributed, they are sent into the world as a new sort, bearing the name probably of the place, or person who first obtained them, such as the Charlton Pea, &c. Thus the different varieties of Peas are obtained, and each respective variety multiplied for public supply: some of which varieties differ very materially from one another, either by their early bearing, or by their larger growth, or the like, though some reputed varieties differ so immaterially that the difference is hardly distinguishable. And it is to be remarked of all these acquired varieties, that although some are tolerably permanent, yet without proper care in saving the seed of each sort separate, they will all gradually degenerate to one another, or to the common white, or grey kind; so that it would in a manner be impossible to pretend to enumerate all the varieties of Peas, or to give any particular description of the different sorts; therefore we shall only exhibit a list of the principal varieties that are at present the most commonly known; which, though pretty many, there are not above five or six that have merit for general culture; some of which are moderate growers, and early bearers, commonly called Hotspurs; others are large growers, and come later into bearing.

Hotspurs, or smaller forward Kinds.] Early Charlton hotspur Pea—early golden hotspur, an improved variety of the Charlton kind—Nicholas earliest hotspur, an improvement of the golden sort—Masters hotspur Pea—Reading long hotspur Pea—dwarf hotspur Pea: with several other reputed varieties of less note, that hardly differ in any thing from the above sorts.

All the above are moderate growers, rising upon sticks only, three or four feet high: and the dwarf Pea scarcely half so much: they are all excellent bearers, producing moderate sized well filled pods; but the first four sorts differ very little from one another, only in some bearing a little earlier than others: the golden kinds are the present earliest bearers, and in the most esteem for the forward crops, though any of the hotspur sorts are proper both for the early and first general crops, or in short, for the principal crops during the whole pea-season, for they are rather sweeter eating Peas than the larger kinds: the Reading hotspurs in particular have great merit to make

make a principal share in the general crops, they being remarkable bearers, and produce fine long pods; and the dwarf Pea is particularly valuable for early crops in frames, &c. or a few may be sowed occasionally in the open ground both for early and later crops, for it is a remarkable bearer for its size; but not proper, however, for any general crop. By different sowings of the hotspur kinds from October or November until spring, they will furnish a daily supply of peas from May until August, or till succeeded by the following larger kinds.

Larger-growing late Kinds] Large marrowfat Pea—dwarf marrowfat Pea—large sugar Pea, having very large bowed pods—dwarf sugar Pea—Spanish Moratto Pea—green nonpareil Pea—rouncival Pea—green rouncival Pea—white rouncival Pea.

These large kinds mostly assume a strong growth, and will rise upon support five or six, or even seven or eight feet high, and produce fine large pods in tolerable plenty; the Marrowfats and Spanish Morattos in particular bear abundantly, and are profitable both for family use and market; but the Marrowfats are most esteemed for the main crops. Observing, all these large kinds are proper to sow chiefly in spring, from January and February until May, to supply the table in July and August; and by sowing late in May and in June, a succession may be continued from the beginning of July until near Michaelmas.

Other Varieties of less Note]. Crown or rose Pea, rising with very thick stalks, bearing its blossom and pods at top, in a large umbellate cluster, valued more for curiosity than profit—painted lady crown Pea—fickle podded Pea—egg Pea—cluster Pea—large grey Pea—crooked grey Pea: with some others of less note.

Great as the above number of varieties of Peas are, they are all the offspring of one species, that have arisen at different times by chance, and been increased by good culture.

The following species is chiefly valued as a flowery plant.

²Pisum Ochrus.

Ochrus, or Winged Pea.] Hath angular stalks growing about a yard long; diphillous or two-lobed leaves, having membranaceous, decurrent, winged foot-stalks; and pedunculi sustaining one yellow flower; succeeded

by oblong pods, containing roundish compressed Peas.

Both the above species of *Pisum*, together with all the numerous varieties of the common Pea, are herbaceous annuals; rising from seed in winter and spring, flower and yield their produce in summer, and totally perish in autumn following; so that a fresh supply must be raised annually from seed; and that to have a regular supply of the varieties of the common Pea for use from the earliest part of summer until Michaelmas, several different sowings from October or November until May or June are necessary; for a crop of Peas continues but about a fortnight in full bearing; but by a repetition of sowings once in three weeks or a month during the above period, a constant succession is continued five or six months.

General Observations.

All the sorts are hardy, and thrive in the open ground in almost any common soil of a garden and field: observing the early sowings should generally be in a warm dry situation, and the general and later crops in any open exposure.

They are all of trailing growth, though of the cirrhose climbing kind, for being furnished with *cirrhi*, or tendrils at the ends of their leaves, that catch hold of any neighbouring bushes or sticks, they thereby climb and support themselves erect, and mount several feet high; which indicates that though they are procumbent or trailing plants, yet by being furnished with clasps, nature seems to have designed that the generality of them should climb and raise themselves from the earth: therefore in their culture it will be found advantageous to allow them support of sticks, which may be practicable enough for moderate quantities, in places where loppings of trees, &c. can be obtained in plenty; and as the Peas are cultivated in rows, by placing a range of such sticks along each row, the plants will readily catch hold and ascend to their tops, and blossom as they advance in height; and both blossoms and pods will be considerably more abundant, and continue longer than those that are suffered to trail on the ground.

They are cultivated always in rows, by sowing them in drills, from two to four feet asunder; that being not only the most commodious method of sowing, but also for the

the nature of growth of the plants, as well as for admitting to do the necessary work, and to gather the produce. See the *Propagation*, &c.

Peas are a most useful and profitable esculent, valuable both to supply our tables with their produce, young and green, all the summer, and also to be dried when ripe, and preserved for winter, when they are most excellent for many purposes, as for Peas-soup, Peas-pudding, &c.

The general season of green Peas for use is principally June, July, and August, by sowings from December or January until May; but by sowings so early as October and November, and continuing a monthly repetition of sowings, as before hinted, we often have Peas daily from the beginning of May to the end of September.

The principal sorts of Peas that merit esteem for general culture, are the early Charlton, Golden, and Reading Hotspurs; the Marrowfats, Spanish Morattos, and Rouncivals; all of which are great bearers, and exceeding fine eating Peas; but where there is large scope of ground, curious persons may raise as many of the sorts as may be convenient: I, however, have observed, that three or four different sorts were always fully sufficient for the general crops; with which the table have been as plentifully supplied during the whole season of Peas, as if all the varieties had been raised, and with much less trouble.

Of the smaller kinds, I should advise the Charlton or Golden Pea, both for the early crops, and for the first general crops, by different sowings, at a month or three weeks interval, from October or November until spring, to supply the table with green Peas from May until July or August; but indeed all the Hotspur kinds are excellent for general culture almost the whole season of Peas, but are peculiarly adapted for the early or forward crops, because they come into bearing sooner than the larger kinds by a fortnight, if both sorts are sowed on the same day. The earliest Golden Hotspurs are the best to begin with for the earliest crops, repeating two or three sowings at intervals, as above suggested; afterwards may be sown any of the other Hotspur kinds, particularly a good share of the Reading or long Hotspurs for the general crop, as being most excellent bearers, producing fine long pods: remarking, that the Hotspur kinds in general may be sowed any time from October until April or May, at intervals of a

month, three weeks, and fortnight; that is, the sowings from October until Christmas, once a month or three weeks will be often enough; and from Christmas until the beginning of March once a fortnight or three weeks; and from March till May repeat the sowings once a fortnight at least: by which intervals of sowing you will have a plentiful daily supply all summer long; each crop continuing in bearing but a fortnight or three weeks, so the different sowings regularly succeed one another.

I have, of the early crops of Hotspurs that come into bearing soon in May, let the gleanings stand for seed, which ripening early in June, have sowed them directly, and gathered a crop of peas from them the same year in August and September.

And of the large kinds, I should prefer principally the Marrowfats, Spanish Morattos, and Rouncivals; to be sowed in spring, &c. for the general later crops, i. e. to bear in July, August, and September; but would give preference to the Marrowfats, particularly the dwarf kinds: for the chief crops, next to these, the Spanish Morattos, then the Rouncivals; the latter of which, though they may be sowed at any time in common with the two former, yet I would also advise to use these sorts principally for the late crops, as they generally endure the drought of summer the best; but any of these large kinds that are most approved, may be sowed any time from January or February until the end of May, or beginning of June; and where variety is in request, some of each sort may be sowed, but most of all of the Marrowfats, beginning with the dwarf kinds first, which indeed is rather preferable for continuance than the large Marrowfats, as this sort requires very great room to grow, and unless they have very tall sticks to run upon to their full length, do not succeed well; but with this assistance, however, it bears wonderfully; so that where there is every convenience, it is proper to sow both these sorts; and to have a regular succession of any or all these large sorts of Peas, continue sowing a few every fortnight, or three weeks from January or February until the end of May or beginning of June, as above observed, though in April and May the sowings should be every fortnight at least; and I would advise the late sowings to be chiefly of the Rouncival kinds: thus by repeated sowings you will have a plentiful daily supply of these large Peas from the beginning of July until the end of September, even some-

sometimes, in favourable seasons, until October.

As to the mode of culture, Peas in general should be cultivated in rows, as we observed before, by sowing the seed in drills drawn with a hoe, from one to two inches deep, allowing abundance of room between the several lines or ranges, for the free admission of sun and air, as well as for performing the necessary culture, and room to go between to gather the produce without breaking down the plants. Allow therefore the smaller kinds not less than two feet or two and a half, between the rows, but if intended to give them sticks to run upon, allow three feet at least, or rather three and a half between the lines in rich ground; and the larger kinds should be allowed a yard between the rows even when no sticks are intended; but if designed to stick them, four feet is requisite, or four and a half for the largest sorts, such as the large Marrowfats and Rouncival kinds. For it is most necessary, where practicable, to allow all the sorts sticks: placing a range of any sort of tall branchy sticks, or brush wood, along each row of plants, when about half a foot high, for them to climb upon for support, whereby they will produce double the quantity of Peas, as when suffered to trail on the ground. This, however, though not very practicable where large quantities are raised in fields for the supply of market; yet for moderate quantities in private gardens, where sticks can be readily obtained, it should never be omitted, as the advantage will be more than double.

Observe always to allow more room by a foot, between the rows for those crops that you design shall have support of sticks, than those that are not; for Peas that have support always grow strongest, and if they have not proper room, the plants of the different lines will interfere, and both interrupt the growth of each other, exclude the necessary influence of the sun and air, and not admit of room to gather the Peas without breaking the plants to the great diminution of the crops; but give them proper room and support, and you will reap the advantage in proportion.

But when intended to allow Peas support of sticks, I have often sowed them in double rows, with very wide intervals between, that is, beginning at one end of the ground, sow two rows together, only a foot asunder; then, if for the Hotspur kinds, leave a space of four feet, or if the large kinds, five feet, and sow

two more rows a foot apart; then allow another wide space, and sow other two close rows, &c. and so proceed throughout: by this practice you have the ground equally filled as if the rows were single and closer; and by the abundant room in the wide spaces, it admits all the advantage of sun, air, and of gathering the produce freely without incommoding the plants.

Seed Peas of all the sorts are sold at all the shops and nurseries at moderate rates, commonly by measure, as by the bushel, peck, &c. or in smaller quantities for private gardens, by the quart or pint.

Their Propagation and General Mode of Culture.

As to propagation, all the sorts are raised from seed, i. e. the Peas sowed annually, the plants, being but of one season's duration, an annual repetition of sowing is consequently necessary; and as those of one sowing continue but a short time in bearing, several sowings are requisite each season, to continue the succession for the table all summer; each sowing to remain where sowed, chusing a warm border, &c. for the earliest crops, and for the succeeding ones, any of the common open quarters are the most eligible, in a free exposure, distant from shade of trees, &c. and open to the free air and sun; fixing on the driest warm soil for the forwarder crops, any common soil for the main crops, and the moistest parts for the late crops.

The general season for sowing is any time in open weather, from October until May or June; but remarking, that during the above period several different sowings are necessary, in order to keep up a constant succession of young Peas for gathering several months in summer, i. e. from May until September; for those sown in October or November, if they survive the winter, come into bearing in May and June, and by repeated sowings at a month, three weeks, and a fortnight's interval till May, as we before remarked, they will furnish a constant supply of Peas all the summer; and those sowed late in May and in June often continue a moderate supply in autumn till the end of September, and sometimes a few in October. With regard, however, to the earliest sowings, from October till the beginning of January, they are liable to accidents from the severity of the weather, and if they all stand the winter, those sowed in October will scarcely be a fortnight earlier

in bearing than those sowed six weeks or two months after: it is nevertheless proper to begin early, and repeat the sowings at the intervals before mentioned, that there may be a sufficiency for substitutes in case of accidents; and also if they all survive, that there may be a regular succession of crops coming into bearing, to afford a daily gathering through the whole season.

But, in order to have green Peas as early as possible, recourse is had to the assistance of hot-beds, by the aid of which young Peas are obtained in March and April, and continued till the coming in of the natural ground crops in May or June.

We, however, will first proceed with the culture of the several principal crops in the natural way; then by hot-beds.

Hotspur Kinds for the early and first general Crops.—In October, November, or December, as may be convenient, begin to sow the earliest crops; though in warm gardens it is always adviseable to sow a few in the two former months; but in open grounds November and December is time enough to begin, chusing the earliest Charlton or Golden Hotspurs; and for their reception prepare a warm south border, or some other dry sheltered sunny situation; and in a dry day draw drills by line, ranging south and north, to enjoy the greater advantage of the sun's influence, making the drills an inch and a half deep, and two feet and a half at least asunder; but if designed to allow them sticks, three feet and a half will be the more eligible distance, as we before observed: then having the seed, or Peas, scatter them evenly along the middle of each drill, rather somewhat thickish at these early sowings in winter, because they are liable to accidents from the insults of vermin, and the inclemency of the season; covering them in evenly with the earth, either with a rake or hoe, or with the feet; being careful that they are all equally covered the depth of the drills; and then with a rake lightly trim the surface smooth, which finishes the work of sowing. The seeds will begin to germinate in a fortnight, if mild weather, and will come up in three weeks or a month, seldom in less time at this season; when the plants are to be managed as hereafter directed.

Having thus performed the first sowing of the Hotspur kinds, then, agreeable to the aforementioned rules, another sowing should be performed in three weeks or a month

after; but if you sowed in October or early in November, it is adviseable to repeat the sowing in a fortnight or three weeks, for fear the first should fail; and after this continue sowing once in three weeks or a month all winter in mild weather, the same kinds, not forgetting towards spring to sow a principal crop of the Reading Hotspurs; observing as the season advances the sowings may be in more open exposures, and more in quantity than the early sowings; and as the spring draws on, the sowings should be repeated oftener; as for instance, from about Christmas till the beginning of March it should be once in three weeks at least; and from that time till May, once a fortnight will be necessary, though as the warm weather increases, a small sowing may be necessary every ten or twelve days. It must be observed, however, these frequent sowings are principally to be understood for practice in private gardens, for the supply of such families that require a daily succession of young Peas during the whole season; but for large quantities in fields, where only a succession of general crops are required just during the principal Pea season, June, July, and August; three or four different sowings from November or December until March or April may be sufficient.

All the different sowing will come up regularly in successive order; but the winter and spring sowings differ materially in the time they require to germinate and come up; those sowed any time in winter are sometimes three weeks, or near a month before they come up; but those sowed towards spring come up sooner; and March and April sowings will often rise in less than a fortnight, especially those sowed in April, and sometimes sowings performed in April and May will come up in a week.

As to the culture of all these sorts after they come up, it is very easy; observe as follows.

According as the plants of each sowing come up, and have advanced two or three inches high, it is proper to begin the first culture by drawing a little earth with a hoe up to their shanks on each side of every row, to strengthen them and forward their growth; at the same time cutting down all weeds: repeating the earthing, &c. once or twice at about a fortnight's interval, or a little more or less as occasion may require; and when the plants are six or eight inches high, those you design for sticks should then be stuck.

But as the earliest crops that come up in November or December, are often in danger from the severity of frosts; it is, therefore, proper, when the plants are about an inch, or an inch and a half high, to draw a little fine earth lightly up to their shanks, in a dry day: likewise it will be of much advantage to give occasional protection to the earliest plants in severe weather, by covering them lightly with long, light, dry litter, of the straw kind, or with mats; which in private gardens, where there is a moderate quantity, in warm borders, might be easily effected: this need only be practised in very rigorous frosts, but be sure to uncover them every fine sunny day, and the moment the frost breaks discontinue the covering entirely; for they must by no means be kept too close, which would draw them up weak and tender; but by a judicious protection, the crop is often preserved in tolerable condition, and forwarded much sooner to bearing than if it had been left entirely exposed; observe also, that according as the plants advance, repeat the earthing up their shanks a little at a time in dry mild weather, at least two or three times till spring; it will protect them the better from frost, strengthen, and forward their growth: this is all they require during winter. In spring hoe up all weeds, and give them a final earthing, an inch or two up their shanks; and then, if intended to allow them sticks, let it be done when the plants are six or eight inches high: having branchy sticks of three or four feet length, stick a range of them along by each row of Peas, on the southerly side of each row; the plants will readily catch hold, and gradually ascend by their tendrils, blossoming as they advance; if, when in blossom, the weather should prove dry, some good waterings in a morning will be beneficial culture; and when the blossoming plants are advanced some considerable height, if they are then topped, it will promote the pods setting more expeditiously, and arriving sooner to perfection.

As to the other succeeding crops of the Hotspur kinds, all they require is hoeing up the earth to their shanks, and cut up all weeds when they appear; and those designed for sticks, should always be stuck as soon as they are half a foot high, or a little more, before the plants begin to fall down to one side; providing sticks for this purpose, about four or five feet long, and place one range to each row of Peas; placing them principally on the south side of the rows, because the plants natural-

ly incline towards the sun, and thereby more readily attach themselves to the sticks.

Larger Kinds for the later general Crops.—With respect to the larger kinds, such as the Marrowfats, Spanish Morattos, &c. we may begin sowing in January, if they are in great request, the dwarf Marrowfats first; though February, March, and April is the most eligible season for sowing the general crops of all the large kinds; observing to chuse a free exposure in the most open quarters, there drawing drills by line, about an inch and a half or two inches deep, and not less than a yard asunder; but if to be stuck, four feet, and for the largest sorts four feet and a half: sow the seed thinly along the middle of each drill, and draw the earth evenly over them with the rake, hoe, or feet, covering them equally the depth of the drills, and rake the surface smooth. Repeat the sowings once a fortnight or three weeks; though as the spring and the warm season advance, once a fortnight will be proper, especially from the beginning of April until the end of May; or in May and June may sow a few once in ten or twelve days: late sowings, however, performed from the middle of May till about the middle of June are seldom very fruitful, being often attacked with the mildew; but in family gardens it is proper to endeavour to have some as long in the season as possible.

When the different crops of these are come up about three inches high, hoe up earth to them on each side of the row; and cut down all weeds, repeating the hoeing occasionally according as the growth of weeds shall require; and when they are half a foot, or eight or ten inches high, those you intend sticking should have the sticks placed to them: observing, these large sorts require sticks six or seven feet high at least, placing them on the sunny side of the rows, as we said for the Hotspurs.

Late Crops.—Any of the sorts, either Hotspurs or larger kinds, that are most approved of, may be continued sowing all May and until towards the middle of June, chusing the strongest moist ground; but I would, however, observe, that for these late crops, the larger kinds of peas are the most to be depended on; and for the latest crops of all, sow chiefly the Rouncivals, they being rather the hardiest to struggle with the summer's drought; but Peas of any sort that are sowed after May is out, are rarely very successful, they being generally attacked by the mildew, &c. it is, however, worth the trial, and if they

they bear but a few after the general season, they will be a rarity; and in sowing the later crops in May and June, if the weather should prove dry and hot, it will be of importance to soak the Peas in soft water six or eight hours previous to sowing, otherwise water the drills well; either of which will promote their rising very expeditiously and more regularly together.

Other general Remarks relative to all the Sorts.

I have observed in performing the different sowings of Peas, with respect to the intervals of time between the sowings, it was a good rule, that as soon as one crop appeared fairly above ground, to sow another to succeed it, whether in winter, spring, or summer; so continuing it to every crop, which will be found an infallible rule in sowing, so as to have a regular succession of crops following one another in bearing.

If a crop of Marrowfats, &c. and another of Hotspurs are sowed on the same day, the Hotspurs will come into bearing a fortnight the soonest, and the Marrowfats will arrive to a bearing state about the time the others are going out, just in due time to succeed them: mark this, therefore, when intended to have these sorts form a regular succession to each other.

Such crops of Peas that you design to indulge with sticks for support, should always have the sticks placed when the plants are from about six to eight or ten inches high, whilst they maintain their upright position of growth; and as at that height they begin to emit tendrils, they will very readily attach themselves to the sticks.

With regard to the sticks proper for sticking Peas, it is incumbent on us to procure such that are branchy, or furnished with many side shoots, and of proper length, according to the sorts of Peas they are intended to support; they may be either the loppings of trees, or any bushy underwood that is well feathered with small lateral branches the whole length, for the plants to run upon; observing, that if for the Hotspur Peas, to prepare them about four or five feet long; but for the large kinds, six or seven feet length will be requisite, or more for the largest Marrowfats, &c. trimming them all somewhat fan-fashion, so as the branches may spread only two ways, to range the way of the rows of the plants, and sharpen the lower end of each: being thus prepared, place one row of sticks to each line of Peas; which will be sufficient, especially if placed on the

most sunny side of the rows, because the sun's influence will incline all the plants that way, and thereby more readily encounter with the sticks; placing the sticks about a foot asunder, or a little more or less, so as the branches of the different sticks meet; and as soon as one row is stuck, then with a hoe draw a little earth up to the opposite side of the rows of plants, to lay them towards the sticks: when the whole is stuck, if the tops of the sticks appear very straggling and unequal, you may just run over them with the garden sheers to give a little air of regularity.

In gathering the product of Peas, both hands ought always to be employed, one to hold the peduncle, or footstalk of the fruit, while the other pull the pods, otherwise the stem or main stalk of the plant, being slender, fragile, and weak, would be very liable to be broken.

The gatherings should always be regular; according as the pods fill, never let them stand to grow old, but gather them whilst young and green, as they are then in greatest perfection for eating, and the plants will continue longer in bearing.

A crop of Peas continues only about a fortnight in full bearing; during which time they will furnish a plentiful gathering of pods in their ultimate perfection; though in moist showery weather they sometimes continue shooting and flowering three or four weeks, but the produce after the first fortnight, is generally inferior both in quantity and quality; hence the necessity of repeated sowings every three or four weeks.

As soon as any crops of Peas that have been stuck are past bearing, take up all the sticks, and tie them in bundles, and set them upright in any dry corner; they will serve another year.

Early Culture by Hot-beds.

By Hot-beds—Where it is required to have a few green Peas as early in the year as possible, recourse is had to the assistance of hot-beds, as we before said, and the proper sort of Peas for this purpose is the dwarf kind, which by this aid may be brought to bearing in March and April, and the following is the method.

It must be previously observed, that it is rather most eligible to raise the plants first in the natural ground, in October or November, till two or three inches high, then transplant them into the hot-bed, in January or beginning of February; for by this practice the luxurian

luxuriant growth of the plants is somewhat checked by removal, so as they will be more easily contained within due compass, and thereby will blossom and bear sooner and more abundantly.

In October or November, therefore, prepare a warm, dry, south border; then having some true dwarf Peas, sow them in drills about a foot asunder, in the manner as for the common crops, when the plants are come up, and advanced a little in growth, then in a dry day draw some fine earth up to their stems, which you will repeat as you shall see occasion during the winter; observing if the frost should set in severe, you must afford them protection, either of frames, or coverings of mats, or else some long strawey litter, being careful, however, to expose them every favourable day, for they must not be drawn up weak and tender.

Then in mild weather, towards the middle or latter end of January, or beginning of February at farthest, prepare a hot-bed for one or more of the largest three-light frames and glasses; the hot-bed may be either be of dung or tan; the latter where it can be obtained easily at a moderate expence, is considerably the best hot-bed for this purpose: however, of either of these materials make the hot-bed two feet and a half or a yard thick, and cover it with frames and lights, and when arrived to a moderate temperature of heat, put on the earth for the reception of the plants, see HOT-BEDS. Chuse any light good dry earth, and lay it eight or ten inches thick all over the bed; then in a dry mild day, take up the plants out of the border with a trowel, raising them with their roots as entire as possible, with what earth will readily hang about; and drawing drills in the earth of the hot-bed, from the back to the front of the frame, a foot and a half asunder, and one or two inches deep, put in the plants in the drills, not more than an inch apart, covering in the earth close to their roots and stems, and give a very light watering, just to settle the earth; which done, put on the lights; being careful to tilt them occasionally at one end to give vent to the steam, &c. observing at first planting, if in sunny days the plants should flag, give a moderate shade in the middle of the day till the plants have taken root.

After this you will admit fresh air to the plants daily in fine weather to strengthen them, by tilting the lights more or less, according to the temperature of the bed and

outward air; but keep them close in cold nights, and cover also with mats; give occasional moderate waterings in fine days; and as the plants advance in growth draw a little earth up to their stems once or twice; repeating the moderate refreshments water frequently as the warm season advances; which may be given more freely when the plants are in bloom: observing according to the advanced growth of the plants and increased warmth of the weather, to give a larger share of fresh air in proportion; and when they are in blossom, observe if the sun at any time appears too violent for them through the glasses, it is adviseable to give a very slight shade an hour or two in the heat of sunny days; likewise when in full blossom and fruiting, be sure to admit plenty of free air, even sometimes in fine days shove the glasses entirely off; still also continue the waterings more abundantly during the time of setting and growth of the pods, and indulge them with the benefit of warm showers.

Thus the plants may be brought to bearing in March and April, and by a succession of two crops, in hot-beds made at three or four weeks interval, and managed as above, you may continue a supply till the natural ground crops come into bearing in May.

Hints respecting the Culture in Fields.

In the field culture of Peas, where designed to raise crops in order to gather the produce green and young for the supply of markets, November or rather December is time enough to begin the first sowings, especially in open exposed grounds; chusing a dry light soil for the forward sowings.

As to the sorts of Peas, any of the Hotspurs for the forward crops, as observed in the garden culture, and for a general crop the Reading Hotspur is excellent; but of the large kinds, chuse principally the Marrowfats and Spanish Morattos for the main crop.

The ground for their reception is prepared by proper ploughing and harrowing; drills are then to be drawn with a hoe, cross ways the lands, or if with a drill-plough length-ways, two feet at least, or two and a half asunder for the Hotspurs, and three for the larger sorts; no sticks being intended for these field crops; and having sowed the seed, cover them in either with a hoe or rake, though this is sometimes performed with a harrow; but the hoe or rake will cover them more evenly, and almost as expeditiously.

When

When the plants come up they must be kept clean from weeds, by broad-hoeing; but this is sometimes performed in fields by horse-hoeing for the sake of expedition; which having hoes fixed in a sort of plough horizontally, is drawn by a horse between the rows, a man holding the plough-shafts to guide it; but as this can only cut down the weeds, a common drawing man-hoe must be used to earth up the plants; though this is often disregarded in the field-culture, it however proves very beneficial to the crop.

Saving Seed of all the Varieties.

To save seed Peas of the different varieties as perfect each in its kind as possible, some of each sort should be suffered to stand entirely for that purpose, or rather sow some of each purposely in different parts, and suffer the whole produce to remain and ripen for seed: this, however, in private gardens is rarely well attended to, for it is a very common practice to gather all the prime whilst young and green for the table, and let the gleanings remain for seed, which, although they will grow very well, and bear in tolerable plenty, yet the produce for the generality will be more scanty, smaller, and tend to degeneracy.

Observing, however, that when intended to raise a quantity purposely for seed, they should be sowed in February in some open ground, in rows two or three feet asunder, no sticks being required, and when the plants come up, keep them clean from weeds by hoeing, and hoe the earth up to their stems once or twice.

When they are in bloom, examine them row and row, to see if there is any degenerate sort to pull it out, or if any improved variety is discovered, to mark it; which is the only method to preserve both the purity of the known sorts, and to procure new varieties; for example, if amongst the Hotspurs any large sorts appear, remove them directly; removing also any Hotspurs, &c. from amongst the large kinds, and different sorts of each of these from each other; and if any new sort discovers itself either by flowering earlier than all the rest, or possessing some other singularity, let them be carefully marked to save the seed of them separate,

According as the seeds of all sorts ripen in July and August, which is discoverable when the pods change brown, and the seed

becomes a little hard, let the haulm be cut or pulled up in dry weather, and exposed in heaps in the sun, turning them every day; and when the seed is become perfectly dry and hard, it may either be threshed out directly, or stacked up in the dry till another opportunity; but whenever it is threshed, keep each sort separate, and when properly cleaned, put them up also separate, in bags or sacks, with a label to each, expressing the name of the variety.

PLANTATIONS, Plantations of trees, woods, &c.

Plantations of trees, &c. greatly embellish and improve estates, as well as ornament the adjacent country; and those formed into woods for timber-trees, prove not only very beneficial to the owners, but may be said to be a public convenience to the country around, to have the opportunity of purchasing wood in the neighbourhood, for the various purposes of buildings, fencings, making all sorts of husbandry implements, as carts, waggons, ploughs, &c. and for innumerable other uses; also for furnishing fuel, a very essential article.

In former ages this island abounded in natural plantations or forests, which spread themselves over the surface of the country, to a very considerable extent, and composed of various sorts of lofty trees of prodigious magnitude, all blended promiscuously together, and all of spontaneous growth. Those vast forests were never planted by any human hand, such only have been employed for ages in cutting them down, for in many places there were such a profusion of useless wood, that large tracts were obliged to be cleared by degrees, in order to cultivate the ground for other purposes; which, together with the necessary demands for the timber from time to time for buildings, &c. and that owners of estates, reaping considerable advantage from the sale of their timber, continued by degrees, one generation after another, grubbing up their timber without measure; and few ever planted any in lieu of what they cut down; so that in many parts there is almost a general demolition of woodland, and many considerable estates have scarcely any timber of value left standing, whence comes the present scarcity in many parts of the kingdom.

Every possessor of estates, either of large or moderate extent, will reap great pleasure and advantage in dedicating some share of his land

land to plantations; for in estates of whatsoever extent, they give grandeur and ornament to the premises, as well as an air of fertility and riches; and those large plantations designed for woods, will, after the first eight or ten years, bring in great profit by a gradual thinning of the underwood, besides leaving a sufficiency of standards to attain full growth: in the mean time the plantations in general will contribute exceedingly to the beauty of the estate; for how delightfully it is for travellers to behold the noble plantations in groves, thickets, clumps, &c. variously disposed in parks, and on the boundaries of spacious lawns, and the like places, formed of a great variety of beautiful trees and shrubs, and to see grand avenues of lofty growth, leading to or from a stately mansion, or some main road, or some adjacent town; and in the out-grounds to observe the Plantations of woodlands, &c. ranging along the sides of hills, plains, and other grounds occasionally; but in estates how fertile soever the soil, yet it appears naked and barren without a proper share of Plantations; on the other hand, when estates are beautifully diversified with Plantations, the whole may be said to form a sort of pleasure-garden; especially as in the homeward Plantations we may have commodious walks of gravel and sand, both private, shady, and sheltered walks, occasionally disposed in many winding turns in the serpentine way, bordered with hardy shrubs and flowers, which will afford most agreeable walking at almost any season of the year, as in summer they afford a screen from the vehement heat of the sun, and at other times shelter from boisterous winds, and cold piercing blasts; there may be also here and there recesses or places of retirement, leading by private turnings from the principal walks; with glades or openings of grass-ground in the midst of the most extended parts of the Plantations. See PLEASURE-GARDEN.

No land-holder, therefore, let the extent be almost ever so moderate or considerable, but ought to appropriate a proportionable share to commodious Plantations as soon as possible, either for ornament or emolument, or both, where the extent will admit, as there is hardly any estate that does not afford soil and situation proper for the cultivation of all our hardy trees, &c. and in many places often furnish soils improper for grass and corn, yet adapted to the growth of many sorts of trees,

which would form good Plantations, and secure to the planter and his posterity a future pleasure and revenue of considerable importance.

In short there is hardly any soil so barren and untractable but what will rear a growth of trees and shrubs of some species or other, both for ornament and advantage; and there is scarcely any kind of tree so bad but may be raised to one or other of those purposes: any very poor ground, or such that lie waste, or at a great distance, cannot be better improved than in Plantations; even although a tract of land should be so poor as to rear nothing but a crop of aspen trees, alder, and willows, yet the profits even of these productions will greatly exceed what many may think.

So that there is a great number of examples to encourage, and warrant success in Plantations, to reward not only with the pleasure of ornamenting his lands, and that of beholding their growth, but also with profit sufficient to compensate amply for the tract of land occupied, and labour in planting.

But to many persons, the necessary expence attending the making a Plantation, and knowing that they must wait several years before the trees have made any considerable progress, or can reap any advantage therefrom, often proves an obstacle in attempting the prosecution of that business; but as to the expence of planting, if you raise the plants in your own grounds, it will not prove near so great as many might imagine, especially as a small spot of seminary or nursery-ground will raise plants enough in three or four years to plant a great many acres of land, both ornamental and woodland; and by the latter, the expence of raising and planting them, together with the loss of time in waiting a few years till the plants attain some growth, will be compensated by the first fall or thinning of the underwood, in eight or ten years after planting; and the stools or roots remaining shoot up again, and afford a lopping every eight or ten years, exclusive of the due portion of standards left at proper distances, to attain full growth for timber, as aforesaid.

One particular precaution in making Plantations, is the judicious choice of such trees as are the best adapted to the nature of particular soils, which may vary exceedingly in estates of great extent; however, such trees as

as we find daily growing by road-sides, hedge-rows, and in any adjacent grounds are rough sketches of what the land will produce.

As to the sorts of trees and shrubs proper for Plantations in general, there is a vast variety, both of the deciduous and ever-green tribes, that will prosper in the open ground in any common soil. See DECIDUOUS and EVER-GREEN TREES, &c.

It is of importance, in making any considerable Plantation, to chuse principally young plants, of from about two or three to five or ten feet stature, which always prove more successful than older trees; for although some persons being in haste to have Plantations as forward as possible in a few years, transplant tall trees, perhaps twelve or fifteen feet high or more, particularly for ornamental Plantations; yet younger growth always take root sooner, and more firmly establish themselves, so as to form considerably the finest Plantations at last, and be of longest duration; for although large trees of from ten to twenty feet height, especially of the deciduous kind, may with care be transplanted, so as to grow and probably thrive tolerably for some years, yet trees more than twelve or fifteen feet high often fail, by not rooting firmly like young plants, and after some years standing, have hardly made any shoots, and at last gradually dwindle and perish; therefore large trees should never be employed for Plantations only on particular occasions, where a few may be necessary to form an immediate shade or blind, &c. in some particular place; but for general work, be persuaded to employ chiefly young plants, either of your own raising, or purchased from the nurseries. And for timber Plantations in particular, I would chuse such plants as are only from about two or three, to five or six feet in height. See PLANTING.

All the different sorts of trees and shrubs proper both for ornamental and timber Plantations, may be had at all the public nurseries moderately reasonable; though persons accommodated with scope of ground, may easily raise all the sorts for his own private use, by the methods directed under the respective genera: a small nursery will raise trees and shrubs enough to plant many acres of land. See NURSERY.

Observe, that where Plantations are intended principally for ornament, as great a variety as possible of the different sorts of hardy trees and shrubs should be employed, to afford the greater source of entertainment; and should consist both of lofty and middling trees, down

to the humblest shrub. See DECIDUOUS and EVER-GREEN TREES. Disposing the deciduous and ever-green plants principally in separate compartments; sometimes arranging the tree-kinds by themselves, some in running irregular Plantations, towards the boundaries of spacious lawns, parks, paddocks, &c. others in avenues, groves, thickets, and clumps, as aforesaid, variously disposed in different parts; and sometimes arranging the trees and shrubs together, in forming shrubberies, wildernesses, shady walks, and wood-works; placing the taller growth backward, and the lower in front; bordering the whole with the most beautiful flowering shrubs, and showy ever-greens, especially next the principal walks and lawns; observing to vary the form of all the several compartments, sometimes by bold sweeps and curves outward and inward, of different dimensions, other parts in long easy bends, irregular projections and breaks, so as to diversify the scene in imitation of a natural Plantations. Allow all the sorts proper distances, which may be from five or ten to fifteen or twenty feet, for example, the tall trees designed for continued Plantations may be from ten to fifteen or twenty feet, varying the distance in different parts, according as light and shade, &c. may be proper; and those in groves, may, if open groves, be fifteen or twenty feet distance, and close groves ten or twelve; for thickets, five or six feet, or closer in particular places where a very dark shade, or thick coverture of wood is required; and in clumps of trees, may allow from five or ten to twenty feet between the trees in each clump, varying the distance occasionally, as also the sorts and numbers of trees in each, from two or three to ten or more: likewise the form of the clumps; some may be triangular, others quadrangular, pentangular, &c. and some in curves, others in straight lines, to cause the greater variety. And as to the shrubby clumps, and wilderness compartments, where the trees shrubs are employed promiscuously together, they may be planted from five to ten feet distance; the taller growth being placed backward eight or ten feet asunder, placing the lower plants gradually forward according to their gradation of stature, to the lowest in front, as above observed, at four or five feet distance: and if the trees and shrubs of the Plantations in general are disposed somewhat in the quincunx way, they will appear to the greater advantage.

But when designed to form large Plantations into woods, &c. composed principally of forest

forest and timber-trees for profit, particular sorts must be chosen, consisting both of deciduous and ever-green trees. Of the deciduous kinds choosing the oak, elm, ash, beech, chestnut, hornbeam, birch, alder, maple, sycamore, plane-tree, poplar, lime-tree, walnut-tree, wild cherry-tree, mountain-ash, larch-tree, willow-tree, hazel-tree, &c. and of the ever-greens, the pine-trees, firs, cedar of Lebanon, holly-tree, bay-tree, laurel-tree, yew-tree, ever-green oak, box-tree, and some others. See FOREST-TREES. The particular description and culture of all of which sorts, deciduous and ever-greens, are exhibited in their proper genera. They are all hardy, and will grow in almost any common soil, rich or poor, and mostly also in dry or moist ground, high or low; allotting, however, particular sorts to very low marshy soils, such as the willow, fallow and osier, poplar, alder, and other aquatics, which will prosper in places that are in a manner covered with water, and are the most proper sorts for the embellishing and improvement of such grounds: all the other sorts will succeed in any other more upland places out of water; observing, with respect to disposition, the deciduous and ever-greens should generally be separate, as observed for the ornamental Plantations. But the trees of the same tribe may sometimes be intermixed, and sometimes different sorts in separate divisions or quarters, as oaks in one, elms in another, &c. remarking likewise in timber Plantations, that all the trees should be planted pretty close together, i. e. not more than three or four feet distance, in order that they may mutually draw each other up tall, more expeditiously, and to allow for a gradual thinning, as hereafter directed.

In forming woods, however, or Plantations of timber-trees, the following hints in respect to planting them are proper to be observed.

Let it therefore be remarked, that there are two methods practised in forming Plantations of woodlands; one is by raising the trees from seed at once on the ground where the Plantation is intended to be, especially of the deciduous kind, and is effected by sowing the seed in drills, a yard asunder, and the plants always to remain where raised, thinning them gradually: the other method is by previously raising the plants in a nursery, till two or three feet high, then transplanting them into places allotted them, in rows the above dis-

tance, to allow also for gradually thinning.

Either of these two methods may be practised, as shall seem most convenient to the owner; but the former, i. e. raising the plants where they are to remain, that although it may be more expeditious, and that at once to get rid of the trouble of transplantation, yet they will require greater attendance for a few years, till the plants have shot up out of the way of weeds; but on the other hand, the trees always remaining where raised, not disturbed by removal, they probably may make the greater progress. The latter method, however, of raising the trees first in a nursery, is rather the most commonly practised, as being thought the least troublesome and expensive, with regard to the attendance at first of the young growth. However, every one is at liberty to make the experiment as it suits his convenience.

The preparation of the ground for the final reception of the seed or plants of these Plantations, is by deep ploughing and harrowing, upon such ground where the plough can be employed; where this, however, or any other tillage is not practicable, we must use only young plants from the nursery, making holes, &c. at proper distances, for the reception of each plant: where, however, the ground can be tilled, it will prove very advantageous, performing it previously a year at least before; sowing it with a crop of turneps, or the like: when these come off, well plough and harrow the ground again, for the reception either of the seed or plants the ensuing season.

The most proper season to perform this planting, either by seed or plants, is any time in dry mild weather, from October or November till February, though November and February are rather the most eligible for most kinds of hardy tree seeds: however, where large tracts are to be planted, both methods must be pursued all winter, at every favourable opportunity.

If seed is intended, you must be well provided with seeds of the several deciduous trees in particular, which may be obtained at all the nurseries and eminent seed-shops; then, for its reception, draw furrows or drills about two or three inches deep, and three or four feet asunder, scatter the seed along the middle of the drills, and cover the earth evenly over them, the depth of the drills or furrows, and place scare-crows and traps to guard against

against the insults of birds and vermin.

But if designed to form the Plantation with young plants, previously raised in beds in the nursery by the common method, let the following practice be observed: chuse always young plants, only from two to three or five or six feet high; and if very large Plantations are intended, you may, to save time and trouble, take the plants immediately from the seed-bed, when one or two feet high, without giving them any previous transplantation in the nursery; though where the Plantations are but moderate, it is most eligible to plant them out previously in nursery-rows, to have two or three years growth: but for remarkable large Plantations, this would be a very great trouble and expence. Being, however, furnished with young plants, they are to be planted in rows, three or four feet asunder, as directed for the seed, and one or two feet apart in the lines: they may be planted either by opening small apertures or holes with the spade for each plant; or, if very small plants, it is sometimes performed by making only a slit or crevice with the spade for each plant; and some open small trenches the whole length, then one inserts the plants whilst another trims in the earth about their roots: some again, in very large tracts, where the situation admits of good ploughing and harrowing to divide and break the earth into small particles, open furrows with a plough, two persons being employed in depositing the trees in the furrow, whilst the plough following immediately with another furrow, covers the roots of the plants with the earth thereof. See PLANTING.

The ground where the above Plantations are made should be previously fenced all round with a deep ditch, &c. to guard against the encroachments of cattle.

Whilst these plantations are young, they must have some attendance to destroy weeds, which may be expeditiously executed by hoeing between the rows in dry weather, particularly by horse-hoeing; and this care will be needful for two or three years, especially the seedling Plantations, till the trees are advanced out of the reach of weeds; after which no farther trouble will be required until the trees are ready for the first fall or thinning, for poles, faggots, &c.

In eight or ten years growth, they will be of a proper size to begin the first fall by a moderate thinning, which will serve for poles and faggot-wood, to pay towards the expence

of planting, &c. but begin lopping only part of the Plantation the first year; thinning out the weakest and most unpromising growth first; leaving a sufficiency of the most vigorous plants pretty close, to grow up for larger purposes; the year following begin thinning another part, and so continue an annual thinning-fall till got through the whole plantation; cutting each fall down near the ground, leaving the stools to shoot out again, especially of the deciduous kinds, and by that time you have made the last fall, the first will have shot up, and ready to be cut again; so the returns of fallings may be contrived to be every six, seven, eight, or ten years, or more, according to the uses the poles or wood are wanted for; and if larger poles, &c. are wanted, the fall may be only once in fourteen, eighteen, or twenty years, still, at every fall, being careful always to leave enough of the most thriving plants for final standards; leaving them pretty close at first, that they may mutually draw each other up in height; but may be thinned every succeeding fall as they encrease in bulk and meet, so as to leave a sufficient quantity of the principal trees at proper distances to grow up to timber, which in their turn, as they become fit for the purposes intended, may also be felled according as there may be a demand for them to the most advantage; having young ones from the stools coming up in proper succession as substitutes, so as the ground may be always occupied.

PLANTING. Planting is the art of inserting plants, seeds, and roots, in the earth for the purpose of vegetation.

There are various methods of Planting in practice for different sorts of plants, seeds, and roots; such as hole Planting—trench Planting—trenching-in Planting—slit or crevice Planting—holeing-in Planting—drill Planting—bedding-in Planting—furrow Planting—dibble Planting—trowel Planting—Planting with balls of earth about the root—Planting in pots, &c. all of which methods of Planting are occasionally used by different practitioners in the several branches of gardening, according as the several methods shall seem most eligible for different or particular sorts of plants. Observing that although most of the different operations are hinted in many different parts of this work in the culture of the various species of each genus, we nevertheless judge it expedient under this head, to exhibit some general directions of the manner each method is performed; together with some

some hints of the kinds of plants, &c. that are commonly planted by the different methods, which may prove useful to young practitioners in performing the mechanical operations of Planting.

1. *Hole Planting*.—This is the principal method practised in the final Planting of all sorts of trees and shrubs in the full ground, by opening with a spade round holes in the ground, at certain distances, one for the reception of each plant. Each hole should be dugged capacious enough to admit all the roots of the tree or shrub freely every way to their full spread, without touching the sides of the hole, and about one spade deep, or a little more or less, or according to the size of the roots, so as, when planted, the uppermost ones may be only about three inches below the common surface, or about as low as they were before in the ground, which is discoverable by examining the bottom of the stem of the tree; though in very humid soils, where the water is apt to stand, the holes should rather be shallow, so as the uppermost roots may stand full as high as the general level, or higher if it shall seem necessary, raising the ground about them, especially in winter Planting: let the holes, however, be of a proper width and depth, according to the above rules, loosening the bottom well; and if too deep, it is easily remedied in the time of Planting, by shaking up the tree as you shall see occasion; observing in digging out each hole, to lay the earth in a heap close to the edge, in order to be ready to fill in again: the holes being ready, then, having trimmed the roots, &c. of the trees, as hereafter directed, place one tree in the middle of the hole, making all its roots spread equally around; a person holding the plant erect by the stem, whilst another with his spade casts in the earth about the roots, taking particular care to break all large clods, and trim in some of the finest mould first all round about the roots in general, shaking the tree occasionally, to cause the fine soil to fall in close among all the small roots and fibres; at the same time if the tree stands too deep, shake it up gently to the proper height, and having filled in the earth to the top of the hole, tread it gently all round, first round the outside to settle the earth close to the extreme roots, continuing the treading gradually towards the stem, to which tread the mould moderately firm, but no where too hard, only just to settle the earth, and steady the plant in an upright position: then pare in all the re-

maining earth evenly round the tree, to the width of the hole, raising it somewhat above the general level of the ground, to allow for settling, giving it also a gentle tread, and finish it off a little hollow at top, basin-like, the better to receive and retain the moisture from rains, and occasional waterings in spring and summer, particularly to the choicer kinds of trees and shrubs.

After performing this Planting, if in winter, or late in spring, it may be of advantage to the choicer kinds of trees and shrubs to mulch them, i. e. to lay some long mulch at top of all the earth, both to keep out the winter's frost, and prevent the drying winds and drought of spring and summer from penetrating to the roots before the trees are well rooted in their new quarters; see MULCH. But some instead of mulch, use grass turfs, turned topsy-turvy, especially when planting upon any grass ground, or any out-plantations where turfs of grass can be obtained; or in orchards, where the ground is grass; in which case it may be proper to bank some turfs round the sides and top of each hole, particularly for large trees, which will steady them more effectually, as well as preserve the moisture, if much dry weather should happen the succeeding summer.

The above work, however, of mulching or turfing new-planted trees, is not absolutely necessary to our common hardy kinds of fruit-trees, forest-trees, and shrubs; though it may prove beneficial to all sorts, but more particularly to the more tender kinds of wall fruit-trees, and more delicate sorts of flowering-shrubs, choice ever-greens, and some kinds of herbaceous perennials.

2. *Trench Planting*.—This method is sometimes practised in the nursery-way, in putting out seedling and other small trees and shrubs in rows; is also used for Planting box edgings; sometimes likewise for Planting small hedge-sets, &c. and always in Planting *Asparagus*, and is performed by opening a long narrow trench with a spade, making one side upright, so place the plants against the upright side, and turn the earth in upon their roots.

If for young seedlings, or other small trees and shrubs, &c. the ground is previously trenched or digged; a line is then set, and with a spade held with its back towards the line, cut out a narrow trench, six or eight inches deep, turning the earth from the line, making the line-side nearly perpendicular; the plants

plants are then inserted in the trench at small distances, close to the upright side, covering in the earth about the roots as you proceed in planting them; and having planted one row, tread the earth evenly all the way along, to settle it close, and fix the plants steady; and so proceed row and row.

But in planting larger trees in the nursery way by *Trench Planting*, a more capacious trench will be requisite: sometimes a trench one or two spades wide, with proportionable depth, according as the roots of the trees shall require; so having opened it all the way along the intended row, proceed to place the trees along the middle of the trench, filling in some earth to each tree as you place it, one person holding it erect whilst another throws in the earth; and having placed one row, trim in all the remaining earth evenly, then tread it closely all the way to fix the plants steady and perfectly upright.

3. *Trenching-in Planting.*]—This is also sometimes practised in light pliable-working ground, for Planting young trees in the nursery-way, and sometimes in Planting hedge-fets, &c. and is performed by digging along by a line, about one spade wide, and Planting as you go on. The method is this, a line is set, then having the plants ready, and with your spade beginning at one end, and standing side-ways to the line, throw out a spit of earth, which forming a small aperture, another person being ready with the plants, he directly deposits one in the opening, whilst the digger proceeds with the digging one spade wide, covers the roots of the plants with the earth of the next spit, and another aperture being thereby also formed, place therein another plant, the digger still proceeding, covers its roots, as before, with the next spit of earth; and so on to the end of the row, placing them at about a foot, or fifteen or eighteen inches asunder, according to the size of the plants; observing, when Planting larger trees with more spreading roots, by this method, that instead of digging the trench only one spade wide, two may probably be requisite for the proper reception of the roots likewise in forming the opening for each plant, make it capacious enough to receive the roots freely, digging the earth over them as above. After having planted one row, either small or large plants, tread the earth evenly along to settle it to the roots, and steady the plants all equally upright.

Another method of *Trenching-in Planting* is sometimes used for Planting some sorts of roots, such as horse-radish-fets, potatoes, &c. performed by common trenching, placing a row of fets in each trench. The horse-radish should be placed in the bottom of the open trench, at fifteen or eighteen inches depth, turning the earth of the next over them; and the potatoe-fets place about six inches deep, and cover them also with the earth of the next trench. See *COCHLEARIA Armoracia*, and *SOLANUM Tumerosum*.

4. *Slit Planting.*]—This method is performed by making slits or crevices with a spade in the ground, at particular distances for the reception of small trees and shrub plants. A slit being made for each plant, which are inserted as you go on; and is practised sometimes in the nursery-way, &c. in putting out rows of small plants, suckers, &c. at from about a foot to eighteen inches or two feet high, and that have but small roots: it is also sometimes practised for final Planting in out-grounds, where very large tracts of forest-trees are intended, and that they are to be planted out at the above sizes, and by the most expeditious and cheapest method of Planting; the following is the method.

A line is set, or a mark made accordingly; then having a quantity of plants ready, for they must be planted as you proceed in making the slits, a man therefore having a good clean spade, he strikes it into the ground with its back close to the line or mark, forms a crevice, taking it out again directly, so as to leave the slit open, gives another stroke at right angles with the first, then the person with the plants inserts one immediately into the second-made crevice, bringing it up close to the first, and directly presses the earth close to the plant with the foot; proceed in the same manner to insert another plant; and so on till all is finished, which is a very expeditious way of putting out small plants, for any considerable plantation. See *PLANTATIONS*.

A man and a boy by this method will plant ten or fifteen hundred, or more in a day.

5. *Holing-in Planting.*]—This is sometimes used in the nursery-way in light loose ground; also sometimes in Planting potatoes, &c. in pliable soils.

The ground being previously digged or trenched, and a line placed, they proceed thus:

thus: a person with his spade takes out a small spit of earth, to form a little aperture, in which another person directly deposits a plant, &c. the digger at the same time taking another spit at a little distance, turns the earth thereof into the first hole over the roots; placing directly another plant in this second opening, the digger covers it with the earth of a third, and so on to the end of the row.

6. *Drill Planting.*]—This is by drawing drills with an hoe from two to four or five inches deep, for the reception of seeds and roots, and is a commodious method of Planting many sorts of large seeds, such as walnuts, chesnuts, and the like; sometimes also broad beans, but always for kidney-beans, and peas: likewise for Planting many sorts of bulbous roots, when to be deposited in beds by themselves.

The drills for all of which purposes should be drawn with a hoe, two or three inches deep, see HOE; though for large kinds of bulbous roots, four or five inches depth will be requisite, covering in the seeds and roots with the earth, always the depth of the drills.

7. *Bedding-in Planting.*]—This is frequently practised for Planting the choicer kinds of flowering bulbs, such as *Hyacinths*, &c. also for larger seeds of trees, as acorns, large nuts, and other larger kinds of seeds, stones, and kernels, and is performed by drawing the earth from off the tops of the beds some inches depth, then planting the seeds or roots, and covering them over with the earth, drawn off for that purpose. The following is the particular method.

The ground must be previously digged or trenched, raked, and formed into beds three or four feet wide, with alleys between bed and bed; then with a rake or spade trim the earth evenly from off the top of the bed into the alleys, from three to four or five inches deep for bulbous roots, and for seeds, one or two, according to what they are, and their size; then, if for bulbous roots, draw lines along the surface of the bed, nine inches distance, place the roots bottom downward, along the lines, six or eight inches apart, but, if seeds, they may be scattered promiscuously; and having thus planted one bed, then with the spade, let the earth that was drawn off into the alley, be spread evenly upon the bed again over the roots or seed, &c. being careful that they are covered all equally the above depth, and rake the surface smooth.

This method is much in practice among

florists for the choicer sorts of bulbous flowers.

The nurserymen also practise this method in Planting many of their larger seeds, nuts, &c.

Another method of *Bedding-in Planting* I have seen practised in some parts, particularly for planting potatoes, in low wet grounds; which is by dividing the ground into beds, four feet wide, with alleys two or three feet wide between bed and bed; then digging the beds, place the potatoe-sets in three rows along each bed, a foot asunder in the row; this done, dig the alleys one spade, casting the soil upon the over the sets, so as beds to cover them about six inches deep: thus if the ground is very wet, the alleys will drain the moisture from the beds, so as sometimes to afford very great crops.

8. *Furrow Planting.*]—This is by drawing furrows with a plough, and depositing sets or plants in the furrow, covering them in also with the plough; and is sometimes practised for planting potatoe-sets in fields, and has been practised in planting young trees for large tracts of forest-tree plantations, where the cheapest and most expeditious method is required; but this method can be practised only in light pliable ground, and is performed thus; a furrow being drawn, one or two persons are employed in placing the sets or plants in the furrow, whilst the plough following immediately with another furrow, turns the earth thereof in upon the roots of the plants.

We do not, however, recommend this method of Planting potatoes for general culture; only persons that have scope of ground may try the experiment.

9. *Dibble Planting.*]—This is the most commodious method for Planting most sorts of fibrous-rooted seedling plants, particularly all the herbaceous tribe; also for planting slips, off-sets, and cuttings both of herbaceous and shrubby kinds; likewise for some kinds of seeds and roots, such as broad-beans, potatoe-sets, Jerusalem artichokes, and horse-radish-sets, with numerous sorts of bulbous roots, &c. and is expeditiously performed with a dibble or setting-stick, therewith making a narrow hole in the earth for each plant, inserting them in each hole, always as you go on; observe the following hints.

Having a dibble or setting-stick, it is used by thrusting it into the earth in a perpendicular descent, in depth as the particular plants, &c.

&c. may require; directly inserting the plant, seed, or set, according as each hole is made, closing the hole immediately by a stroke of the dibble. So proceed dibbling the holes and Planting as you go on, at particular distances and depths, according to the nature of the Plants, &c. as exhibited in their respective genera: observing, in setting any kind of plants, slips, cuttings, and the like, having long shanks or stems, it is proper to make holes a proper depth, to admit them some considerable way in the ground; for example, cabbage plants, favoys, &c. should be planted down to their leaves; slips and cuttings should be inserted two parts of three, at least, in the ground; being particularly careful in dibbling-in all sorts of plants, to close the holes well in every part about the roots, by striking the dibble slantways into the ground, so as to strike the mould first firmly up to the root and fibres, at the same time bringing it close to the stem; for in dibble Planting, many only strike the earth about the neck of the plant, and the lower part of the hole is often left hollow about the roots; but by striking the dibble first at the root-part, you fix the plant effectually, then a stroke of the dibble at the top of the ground finishes, by closing up every part of the aperture. In this manner continue Planting and finishing each hole as you go on, perfectly close that neither the sun, air, nor penetrating winds can enter, this being of much importance; but often disregarded, as we may often see the holes that are necessarily made in fixing the plants left open, which may be easily closed as they go on with the utmost facility, each hole at the insertion of its plant, at one stroke of the dibble, as above said.

For the sorts of dibble, and some other particulars in dibble Planting, see DIBBLE.

10. *Trowel Planting.*—This is performed with a garden-trowel, which being made hollow like a scoop, is useful in transplanting many sorts of young fibrous-rooted plants with balls of earth about their roots, so as they may not feel their removal. See *Planting with Balls of earth, &c.*

The trowel is employed both in taking up the Plants, and planting them; observing the plants having been previously pricked out from the seed-bed or elsewhere, at certain distances, and having been of some standing for their roots to have got good hold of the ground, they by aid of the trowel may be

readily taken up, each with a good ball of earth about all its roots; and then with the trowel making a hole for it in the allotted place, insert it in the hole with the whole ball of earth entire, and give a little water: thus the plants will scarcely feel their removal, and often continue their growth without loss of time, as if they had not been transplanted at all.

11. *Planting with Balls of Earth about the Roots.*—This is the removing a plant with a large ball of earth about its roots, so as the plant by having its roots firmly attached to the surrounding ball of earth, it still, during the operation, continues its growing state without receiving any or but very little check from its removal; and is often practised more particularly to the more delicate and choicer kinds of exotics, both trees, shrubs, and herbaceous plants: likewise when intended to remove any sort of tree or plant out of the proper Planting season, as very late in spring, or in summer, it is eligible to transplant it with a good ball of earth to preserve it more certainly in a state of growth. Observing, some trees and shrubs are more difficult to remove with a ball than most kinds of herbaceous fibrous-rooted plants, though many of the tree and shrub kinds, having very fibrey roots, they will also readily rise with good balls.

However, in transplanting any of the tree and shrub kind by this method, if they grow in the full ground, we must be careful to begin to open a trench with a spade at some considerable distance round the stem, perhaps a foot, or two or three, according to the size of the tree and expansion of the roots, digging a sort of trench all round, a spade or two wide, or more if large trees, and in depth below all the roots; all the time having great care not to disturb the ball, or mass of earth between the stem and trench, but preserve it as entire as possible, for if we loosen this part about the roots, the intended effect of still preserving the tree in a growing state, will fail. Having, however, dug down below the roots all round, you must then undermine the ball on every side, below all the roots, till the whole ball is detached from the main ground; then remove the tree with its entire ball carefully to its destined place, having a capacious hole ready opened, if for the full ground, or if for pots have such that are some inches wider than the ball to admit of a portion of fresh earth all round; in either method, however, plant the tree or shrub with its

its whole ball entire, and fill in the earth evenly all round it, pressing it gently down, and give a moderate watering round the outside to settle the earth close to every side of the ball, then place a stake for support.

But when trees or shrubs, with balls to their roots, are intended to be sent to any considerable distance, they should be placed in osier baskets, in order to preserve the cohesion of the ball, having a basket for each tree; the baskets to be of an upright make, in width and depth in proportion to the ball, with two handles at top, and worked rather open at the sides, because sometimes the basket and all is placed in the ground, when the plant cannot be readily removed without danger of breaking the ball of earth; so that the sides being a little open, the roots may have liberty to shoot out; most basket-makers know how to make them. Having, however, the baskets, put a little good earth in the bottom of each, then place the plant with its ball, fixing it properly in an upright position, observing likewise, in their carriage to the allotted places, to preserve them in an upright posture. In Planting them, if they cannot be readily moved out of the baskets without disturbing the ball of earth, plant basket and all as abovesaid; cut it here and there in the sides, and throw some fine mould close all round so as to join with that of the ball, and give a watering to settle it more effectually close; the roots and fibres will readily make their way through the sides of the basket; besides, the baskets will soon rot, without proving any obstruction to the growth of the plants.

But sometimes, instead of baskets, smaller young trees and other plants with balls, intended to be sent to any distance, are placed in pots, one plant in a pot, and if they are to be placed in the full ground, turn each out of the pot with the ball entire; or if it seemingly will not readily quit the pot without separating, break the pot, to preserve the cohesion of the ball.

Many sorts of herbaceous fibrous rooted plants, however, may readily be taken up with balls with very little trouble, by reason of their numerous fibres, to which the earth closely adheres in a compact lump all round the root; and with a spade or trowel may often be taken up with balls with the utmost facility, and in some sorts the earth of the ball will cling so close as to admit of being sent to some distance without being potted; others

again being less fibrous, require the assistance of a pot to preserve the ball entire till arrived at its place of destination.

And as to trees and other plants that have generally grown in pots, the transplanting them with balls is very easy, for if they have been of some standing in the pot, the whole earth thereof will by means of the numerous fibres, be formed into one compact lump, as it were, that it will readily come out entire and firm; or to such as do not so easily quit the pot, thrust a long blade of a knife, or some other thin instrument, down between the outside of the ball and pot all round, it will then readily come out either in drawing by the stem of the plant, or, by striking the edge of the pot with something; or, if small plants, may turn the pot mouth downward, and strike the edge gently against any thing: observe, in replanting those potted plants, that if the sides of the ball of earth is much matted with the fibres of the root, it is proper to pare off the grossest part, together with a little of the old earth, especially if to be planted in pots again; then Planting it in a pot a size larger than before, filling up all round with fresh mould, and finish with a moderate watering. See *Planting pots*, below.

The advantage in Planting with balls, either in the full ground, or in pots, is, the root of the plant being enclosed in the ball of earth, continues all the while drawing nourishment, and the growth of the plant is not retarded in waiting till it has taken fresh root in its new place, which may be of advantage in many cases, particularly all tender plants, some of our choicest ever-greens, and many kinds of herbaceous flower plants.

But Planting with balls is not recommended for general practice, for all the hardy tree and shrub kind it would be needless as well as very expensive and troublesome.

12. *Planting in pots.*]—This is practised to all tender exotics, in order for moving them to shelter occasionally, such as all kinds of green-house and hot house plants; and it is likewise practised for many sorts of hardy flowering-plants, for the convenience of moving them occasionally to adorn any particular compartments; and for the convenience of moving some curious sorts when in flower to occasional shelter from the sun's rays, and excessive rains, in order to preserve their beauty and prolong the time of their bloom; such as the fine auriculas, carnations, &c.

In

In Planting in pots, it is highly requisite carefully to adapt the sizes to the size and nature of the different plants intended to be potted; if small plants, begin first with small pots, one plant only to each pot, especially if to remain; but according as the different plants advance in growth, shift them into pots one or two sizes larger, which may be requisite to many sorts once a year, to others once in two or three years, according to the nature and encreased growth of the respective plants: though to some sort of annuals it may be necessary once or twice in the course of a season; all of which is generally particularized in the culture of the various sorts. And by thus beginning first with small pots adapted to the size of the plants, it is not only cheaper and more commodious for moving and stowing them in different parts occasionally, till they gradually advance in growth, but by thus shifting them into pots a size larger, it admits of adding fresh earth, which proves highly beneficial to their growth.

Garden pots for the reception of plants are of several regular sizes, from two to sixty in a cast, so are distinguished at the pot-houses accordingly, as twos, sixes, twelves, sixteens, twenty-fours, thirty-twos, forty-eights, sixties, or sixty-fours, &c. in each cast; each pot having one or more apertures at bottom to discharge the superfluous moisture. They are sold by the potters at so much per cast, large and small, all of a price; those of only two in a cast the same as those of sixty; and from two shillings to half a crown per cast is the general price. See POTS.

But with respect to the particular method of Planting in pots in general, the following particulars are necessary to be observed.

Having the pots and mould ready for the reception of the intended plants, observe previous to planting them to place some pieces of tile, potsherds, or oyster-shell over each hole at the bottom of the pots, both to prevent the holes being clogged and stopped with the earth, and the earth from being washed out with occasional watering; also to prevent the roots of the plants getting out; then having secured the holes, put some earth in the bottom of each pot, from two or three to five or six inches or more in depth, according to the size of the pot, and that of the roots of the plant; this done, insert the plant in the middle of the pot upon the earth, in an upright position, making its roots, if without a ball of earth, spread equally every way; directly adding a quantity of fine mould about

all the roots and fibres, shaking the pot to cause the earth to settle close thereto; at the same time, if the root stand too low, shake it gently up as you shall see occasion; and, having filled the pot with earth, press it gently all round with the hand, to settle it moderately firm in every part, and to steady the upright posture of the plant; raising the earth however within about half an inch, or less, of the top of the pot, it will settle lower; for some void space at top is necessary to receive waterings occasionally: as soon as the plant is thus potted, give directly a moderate watering, to settle the earth more effectually close about all the roots, and promote their rooting more expeditiously in the new earth; repeating the waterings both before and after they have taken root, as occasion requires.

In transplanting plants in pots from one pot to another, they may for the general be shifted with the whole ball of earth contained in the pot about their roots entire, so as to preserve the plant all along in its growing state, as scarcely to shrink or retard its growth by the operation of removal; which to plants growing singly in pots, and of some standing, whose roots and fibres have established themselves firmly in the earth, they will readily remove out of the pots with the entire ball in one compact lump, surrounding all the roots and fibres, retaining their growing state by still drawing from the surrounding ball of earth.

The method of removing them out of the pots with balls, is generally easily effected to most potted plants. Sometimes it is performed by turning the pot mouth downwards, and striking the edge against something; the plant will come clean out, with the whole about all the roots entire. Or, sometimes plants that are very well rooted, and its numerous fibres surround the outsides of the ball, it will often readily quit the pot by drawing it by the stem; or at least, if raised a little from the ground, and strike the edge of the pot or tub, the ball will often come out whole and compact. But if by either of the above methods the ball will not readily quit the pot, thrust some narrow thin instrument of iron, such as a long blade of a knife, &c. down round the sides, as already hinted, the ball will then come out with much greater facility. Sometimes however large plants of some years standing unshifted, will by their encreased roots have so wedged themselves, as to require the pot to be broken in order to preserve the ball. And sometimes large plants

in heavy tubs, such as orange and lemon-trees, require to be flung by the stems upon some temporary erection, to draw them out of the tubs with the ball entire.

Having however removed any plant with its ball for replanting in a larger pot, observe preparatory to Planting it, that as sometimes the numerous fibres will have so surrounded the outsides of the ball, as to form a sort of mat all around, it is proper to trim the grossest of them off close with a knife, all round the sides and bottom; then having the pots of proper sizes, larger than the former ones, and having secured the holes at bottom, and put in some fresh compost, deposite the plant with its entire ball in the pot, minding that it stands erect, and just the proper depth; and fill up the interstice all round the ball with more fresh mould, pressing it down round the sides with your hands or a stick, adding more mould gradually; and raise the whole about an inch over the crown of the ball, and finish with a moderate watering to settle the new earth close in every part.

But in transplanting from one pot to another with balls, is in some cases to be avoided; for example, if a plant appears diseased or in a bad state of growth, it is most probable the fault is in the root or earth; therefore in transplantation it is eligible to shake the whole entirely out of the earth, in order to examine its roots, and trim off all decayed and other bad parts; then, having a fresh pot, and some entire new compost, replant your tree, &c. therein, as already directed.

In potting plants from the full ground, or beds of earth, &c. that, if they have been previously pricked out at certain distances, and have stood long enough to fix their roots firmly, many sorts may also be potted with balls, particularly most of the herbaceous, fibrous-rooted kinds, by taking them up carefully with a garden trowel, or with a spade, as may be most convenient; and, if necessary, pare the balls round to fit the pot, planting them as above.

Potting of seedling plants however immediately from seed-beds, that, by their growing so close together, rarely admit of potting with balls to their roots; so that when intended to pot such, they must be drawn out of the earth with the root as entire as possible, and potted separately in small pots, shifting them occasionally into larger, as before observed.

Sometimes in Pot-Planting, we, to save

room, plant several plants in each pot, especially when designed as nursery-pots, to receive either small seedlings, off-sets, slips, cuttings, &c. just to strike them, and forward them a little at first, either in hot-beds, or for removing them to different situations, such as occasional shade, shelter, &c. but when such seedlings are a little forwarded, or the off-sets, slips, cuttings, &c. are properly rooted, and shoot a little at top, they should be all potted off separately, each in a separate pot, especially if plants of any duration; giving them small pots at first, and as they encrease in size, shift them into larger pots accordingly.

When any large growing plants, such as orange and lemon-trees, or any other kinds, are become too large for pots, they should be shifted into tubs: these tubs should be made of full inch-thick staves, and adapted to the size of the respective plants; each tub well hooped with iron, and with two hooked iron handles at top, to receive poles between two men for moving the plants where occasionally wanted; having holes at the bottom of the tubs to discharge the superfluous moisture, as observed for the pots; placing some stones, &c. to prevent the holes being clogged with the earth; the method of planting and transplanting being the same as in Pot-Planting.

In the culture of all plants in pots it is proper to stir the surface of the earth now and then an inch or two deep, to prevent its binding or becoming mossy, and to promote the growth and health of the plants: likewise to such as are not shifted annually, it is also proper to add a little fresh mould in spring and autumn, previously stirring the old at top as above, and a little way round the sides; then taking out the old, replace it with an equal portion of fresh compost, finishing with a moderate watering; this will prove a very beneficial dressing to the plants, and give an air of neatness, and a more lively appearance to the whole.

In all plants in pots or tubs great care is requisite in supplying them with water, which must be observed to most sorts the year round, but more particularly in summer; for the earth containing the plant being limited to the compass of a small pot or tub, it dries very fast in hot weather, so must be often moistened accordingly; which to some plants may be requisite three or four times a week in the summer season; and to some sorts in small pots every day, or even twice a day in
very

very dry scorching weather: but as the autumn and cold season advances, give the waterings more seldom and sparingly; and in winter, plants that are exposed abroad in pots rarely require any water at all; but those in the green-house or other place of shelter must be watered occasionally also during the winter; some probably once a week, or ten or twelve days, such as all the woody kinds; others but once a fortnight or month, particularly the succulent kinds; and some of the more tender very succulent sorts will require very little moisture at any time, but especially in winter; being careful however always to water all sorts in pots moderately in this season of the year, and let it always if possible be done in sunny days, and give very little in frosty weather: at no time give too much to render the earth miry wet in winter, which would prove the destruction of most tender exotics; all that is necessary is to preserve the earth very moderately moist. Potted plants in hot houses however will require more frequent supplies of water in winter than any other plants in pots.

To potted plants in general we must occasionally examine that the holes at bottom are sufficiently open to discharge the superfluous moisture from occasional waterings, &c. for if these are clogged up, and detain the moisture, the consequence will be bad, for it will rot the fibres, and even the main root, and soon bring on the decay of the whole plant; however by turning up the bottom of the pot, the holes if stopped are easily cleared with the end of a stick or other instrument.

Other general Observations of Tree Planting in particular.

Having exhibited above the various methods of performing the mechanical operation of Planting, we will next give some hints with respect to the preparation of plants previous to Planting, particularly of tree Planting, which being of the greatest importance, shall first exhibit some general remarks on that head.

In the first place observe, with respect to Planting trees of all kinds, that it is of considerable importance to give them their final transplantation whilst they are young, i. e. from about two or three to six or seven years old, and when of from about two or three, to six or seven feet stature; especially for all kinds of fruit-trees and forest-trees for long duration; as at the above ages and statures they will establish themselves sooner and more

firmly in the ground than trees of more considerable age and growth, and in the end make the most prosperous and durable trees.

Note, however, trees ten, fifteen, or twenty feet high are occasionally transplanted, especially some deciduous forest and ornamental trees in particular cases; in forming ornamental plantations, where persons are in haste to have any part thereof appear conspicuous as soon as possible, or to afford immediate shade or shelter, as to form blinds to any particular compartment.

But there are many sorts of trees and shrubs of eight, ten, or twelve feet stature, both deciduous and evergreens, that may be readily transplanted with tolerable success; as, if taken up with a good spread of roots, they will take root freely, and often assume a good free growth; these sizes however are more proper to be employed occasionally in ornamental plantations, to exhibit immediate shew, than for any general plantations of fruit and forest-trees.

And as to trees of fifteen or twenty feet height or more, although they may on particular occasions in ornamental works be transplanted, by care in removing them with a good compass of roots, or sometimes with balls, as may occasionally be practised to such in particular that happen to grow on grass ground; and are not to be removed to any great distance; yet the transplantation of these large trees should not be attempted for any general purpose, but only in cases where a few trees may be required to form an immediate shew in some particular compartment, or to form present shade, shelter, or blind, as aforesaid, till younger trees grow up; for they rarely establish their roots like younger growth, but often assume a stunted habit, and frequently after a few years dwindle gradually off; so that when such are employed, it is proper to have some younger trees near them to be advancing as substitutes if any of the others should fail.

However, for any general plantations, either of fruit trees, forest trees, or ornamental trees and shrubs, let them be composed principally of young plants from about two or three to six or eight feet height, as these sizes will be found to root more expeditiously and effectually, as well as shoot more freely at top than large transplanted trees, and sooner attain a state of perfection.

But forest-trees in particular, that are intended principally for timber plantations, it is most eligible to plant them out finally when

from two to four or five feet high, that they may establish their roots firmly in their minor state, which is of considerable importance in promoting a flourishing and durable growth, so as they may sooner attain a great stature and magnitude.

In the work of Planting trees, &c. the choice of them in the nursery for furnishing the respective plantations should be particularly attended to; that, whether in your own ground, or in the public nurseries, always chuse the straightest, most vigorous, and thriving plants of the respective kinds.

Likewise in preparing for Planting, observe that in taking up the trees for that purpose out of the nursery, the greatest care is necessary in raising them with as great a spread of roots as possible; which however is often ill attended to, especially when large orders of plants are to be drawn in a hurry. The ground about the trees should always be opened with the spade widely round the roots, and deep enough to get to their bottom without hacking and cutting them with the spade, but so as to raise each plant with all its roots as entire as possible, for this is of much importance in the future prosperity of the trees and shrubs.

After having taken up the trees out of the nursery, &c. it is of great moment to have them replanted as soon as possible in the places allotted for them; for, although by properly covering the roots with litter, or, if sent to any considerable distance, that by tying them in bundles, and packing them up with plenty of straw about the roots, and afterwards closely matted round, they may be preserved in tolerable good condition a fortnight or longer; yet where it is possible to plant them the same day, or in a day or two after, before the small fibres are shrunk or dried, it will be of much advantage in the first growth of the trees; observing however, after trees or shrubs are taken up in order for Planting, and that either the ground not being ready, or any other hindrance prevents their being planted soon after, they should as soon as possible be deposited in a trench of earth by the roots, which gardeners call *laying them by the heels*, and so take them out as they are to be planted.

Next with respect to preparing the trees for planting, after being drawn out of the nursery.

In the first place with regard to the root; this part must have an occasional trimming, not however to retrench or reduce any but the maimed and decayed parts; therefore

previous to planting each tree, examine the root, and cut out all such parts as have been broken or damaged in taking up, and all decayed parts and other blemishes, being careful to leave all the sound roots every where entire; leaving also all the small fibres that are fresh and vigorous, and only trim off such as are become dry and mouldy; suffering all the main roots to remain, mostly at full length, except just to tip off their ends a little on the under side, sloping outward; and reduce any very long stragglers, and shorten long perpendicular tap-roots, more particularly of fruit-trees, to prevent their running down into a bad soil, and promote their throwing out others horizontally into the good earth.

Some persons however make it a rule to retrench or thin the roots of transplanted trees very much, and shorten them also very considerably; but it will be found that trees planted with all their sound roots, will be the most prosperous in growth; for the reducing the roots with too much severity, greatly weakens the tree; and, as every one must know, that all plants and trees receive invigoration, and their most essential nourishment from the roots and fibres, so that it is certainly an act of high imprudence to destroy the roots of any tree that are good and sound in every respect, and wait a considerable time for new ones, when we are actually possessed of a sufficiency that are good; it is therefore consequently the safest way to leave all the good roots, and only retrench blemished and decayed ones, as already observed.

And with regard to the preparation of the head of the trees previous to Planting, the principal care is to trim off straggling shoots and branches from the stem, leaving the head for the generality entire, only just retrenching very irregular branches, and shortening any very long stragglers; and always suffer the main or leading top shoot to remain at length, to aspire in height as fast as possible, particularly forest-trees, and all others that we design shall grow to a lofty stature, for in this consists their beauty and worth.

With respect to fruit-trees however, sometimes a more accurate regulation of the head preparatory to Planting may be requisite, more particularly dwarfs for espaliers and walls. For example, if the fruit-tree is taken from the nursery at one year old from the budding and grafting, and with its first shoot from budding and grafting entire; this first shoot must necessarily be shortened or headed down.

down to force out lateral wood to furnish the bottom properly; but observing this heading down is not necessary at the time of Planting, and is most eligible to plant the tree with its said first head entire, to remain till spring, until the tree has taken fresh root and begins to shoot; for the head remaining will greatly promote the rooting: then in March or beginning of April, the tree having taken root, as you will observe by its effort for shooting at top, head it down within half a foot, or five or six eyes of the insertion of the bud or graft, and the shoot so headed will throw out several lateral branches the ensuing summer.

On the other hand, if the fruit-tree is two, three, or more years old from the budding and grafting, and the first shoots headed down in the nursery at the proper time, and that in consequence thereof, produced several lateral shoots, to give the head its first formation; or even if the tree has stood long enough to form a good full head, it is proper in both cases to plant it with its whole head entire; only retrenching any irregular branch, or any very luxuriant shoot; or thin out the worst of such as are evidently too close or crowded, leaving however all the regular branches, suffering them to remain also at full length, except just to reduce any very long rambler consistent with the extent of the other branches.

For in new Planting trees it is very improper to retrench the branches too severely, and cut all that remains short, as is very often practised in transplantation, on a supposition to strengthen their roots, which however has often the contrary effect; for the branches and leaves imbibe the refreshing influence of the air, &c. which, being conveyed to the roots, proves nutrimental, and contributes exceedingly towards vegetation, and consequently promotes the rooting afresh more expeditiously and effectually; and until this is well effected the tree will make but little progress in its top growth.

Besides, by a severe retrenching, and a general shortening, of fruit-trees in particular, they cut off the very parts where fruit would have been soon first produced; and probably cost the tree two or three years growth to furnish new branches equal to those cut away, as well as retard its bearing in proportion. And it often happens by such a general amputation of the branches of all new planted trees at the time of Planting, they, for want of branches to collect vegetative nourishment, either make very little progress in shooting for two or three

years after; or sometimes when they do shoot, throw out a profusion of unnecessary wood from the remaining eyes or buds.

For, as we formerly observed, that although shortening the branches of fruit-trees in particular is sometimes proper in young trees of one or two years old from budding or grafting, to force out a supply of lateral wood to furnish the first regular formation of the head, more particularly dwarfs for espaliers and walls; yet if you are about to transplant the tree, and the operation of heading being necessary as above, it ought not to be done till after the tree is planted, and has begun to take root and make an effort for shooting in March or April; for when headed down at Planting, they, for want of the head, rarely either strike root or shoot at top so freely.

Therefore if fruit-trees at Planting, whether dwarfs or standards, are furnished with five or six or more good regular branches, of one, two, or more years growth, it would be a great pity to retrench them, and disfigure the tree, either on the consideration of strengthening it, or to force out more branches; particularly apples, pears, plums, and cherries, which should at all times be but sparingly shortened; and since several good branches being already obtained in the proper parts, to give the head its first regular form, they will in their turn readily furnish more; and if there is a vacancy in any part, it will be better to endeavour to fill it by stopping some of the young shoots produced the summer after Planting, by either pinching them in May or June the same year to three or four eyes, or cut them down to that length in winter or spring following.—Some fruit-trees however, such as peaches, nectarines, &c. against walls, require most of their young shoots to be shortened annually.—But for more particulars of all the sorts, see their respective genera.

Standard fruit-trees, when designed they shall form spreading heads, branching out near the top of the stem regularly all around, they, if grafted high in the stem, must, like the dwarfs, have also the first shoot from the budding or grafting, headed down to four or five eyes, to force out a set of lateral branches near the insertion of the bud or graft; or, if the grafting and budding was performed near the ground, and the first shoot trained to a proper height for a stem, it is also topped at the desired height, to throw out a supply of lateral branches each way, near the head of the stem, as above said; but sometimes when the first heading,

in either of the above methods, does not furnish a proper supply of branches to give the head its first proper formation, a second heading is occasionally performed the next spring, upon the shoots produced from the first; observing, however, that all the above works of heading standard fruit-trees, in particular, should always be performed in the nursery a year or two, or more, previous to final transplantation into the garden or orchard, that the trees may be furnished with several regular branches to form a head, at the time of Planting; and, as before observed, it is proper to plant it with all its said head entire; except reducing such irregular growths as already mentioned, so leaving all the regular branches at their length, suffering the whole to shoot up, and branch away in their own way; and they will annually advance in length, and gradually furnish laterals to fill and spread the head proportionably.

But remarking particularly that standard-fruit trees, having been previously headed in the nursery a year or two or more before, and in consequence are now furnished with several regular branches of one, two, three, or more years growth, they should on no consideration be either retrenched or shortened, neither at Planting nor afterwards, for the reasons before given; and also that as most fruit-trees begin to blossom and bear first towards the upper parts of the branches, more particularly apples, pears, plums, and cherries, which always produce their fruit upon short shoots called *spurs* or *fruit-buds*, that mostly rise first towards the ends of the branches; but which in this shortening would all be cut away, and retard the bearing two or three years, besides all the other disadvantages above mentioned.

But when standard fruit-trees are required to aspire more considerably in height, rather somewhat pyramidal, or conic ways, than horizontally; no heading at all should be practised, neither in the nursery, nor at the time of final Planting; but the whole, quite from the budding or grafting, suffered to remain entire, and shoot up, and branch according to nature; and they will naturally form a regular head. Some sorts spherically, others more of the pyramidal, or conic figure.

As to forest trees, &c. their preparation, previous to Planting, after being drawn out of the nursery, is only to trim the blemished roots, as before observed; and prune off all branches from the lower part of the stem,

cutting them to about from three to five or six inches, particularly the deciduous kinds, leaving the head always tolerably branchy, and mostly entire; not to trim away all the branches to one leading shoot only, as is often practised; but leave a proportionable share of the upper more erect branches, to form some head, and only just retrenching the lower stragglers, very long rambling luxuriant, and very irregular growths, just to preserve a little regularity; being particularly careful to leave always the top or leading shoot perfectly entire; unless it is decayed, or is very crooked, bending much downwards, &c. in which cases, if any straight shoot is conveniently situated, the crooked part may be retrenched down to the straight shoot, which leave entire to run up in height; as without a leader a tree can never aspire to any considerable stature: for the leader, by its annual erect shoot, gradually encreases the length of the stem, and as it advances, sends out a supply of laterals to furnish the head, branching and spreading in proportion, according to the natural growth of the respective sorts.

But in Planting tall trees, where designed to form shade, shelter or blinds, as soon as possible, very little reduction of the branches of the head may be necessary, only to reduce any very irregular growers.

However, in removing pretty large trees of any sort, with considerable heads, especially of a very spreading or crowded nature, it may be proper to reduce the whole regularly, both in some proportion to the root, and that the winds may not have too much power to incommode it after Planting; in which cases, it may be necessary, as just above observed, to retrench, or reduce some of the most extensive lower branches; thin out some where much crowded, and reduce others down to some convenient lateral branch they may support; so as each reduced branch may, notwithstanding its reduction, terminate in a leader, having its top entire, not to exhibit naked ends of branches, standing up like stumps. Observing, however, in such large trees, that the above reduction should be so judicious, as the remaining branches may still exhibit a moderately full, and somewhat regular head.

With respect to the preparation for Planting of all the shrub kind, only just trim straggling under-branches and shoots from the lower part of the stem; retrench luxuriant of the heads that seem to shoot away very irregularly

regularly and vigorously, at the expence of the neighbouring branches; and reduce long ramb'ers, &c. just to preserve a little regularity.

All new planted tall trees, should generally be staked as soon as planted, in order to support them steady every where, till well rooted, and have somewhat established their roots, that tempestuous winds may not over-set, or otherwise incommode them; particularly all trees of six or seven feet high, and upwards. One tall stout stake to each tree, or more, if the trees are of large size, sharpening the lower ends, and drive them firmly into the ground near the stem; or, if larger trees, place it slant-ways, at a little distance, so as its top reach the upper part of the stem, on the opposite side to that most exposed to the winds, in which it will have the greatest effect; but large trees, with full heads, should generally have very tall strong stakes, three to each tree, placed triangular-ways, also in an oblique or slanting direction. Having, however, fixed the stakes in either of the methods, as the trees shall require, then directly proceed to bind the stem of the trees firmly to the stakes, previously wrapping some soft substance, such as hay-bands, &c. round the stem, at the part where it is to be fastened to the stakes, in order to save the bark from being rubbed off against the stakes, by the motion of the winds: and this is more particularly necessary to tall plants that are much exposed. Having some strong bandages, such as rope-yarn, or the like, or for smaller plants some tough osier or other withies, then bringing the stem and stakes close, so as to preserve still the erect position of the plant, bind them firmly together, by drawing the bandage round the stakes, and about the stem, over the hay wrapping, if any, and fasten it so securely, as to admit of no motion between the stake and stem of the tree.

But large trees, of some considerable stature, with full heads, are often supported also with ropes suspended from the top of the stem, three different ways, straining them tight, and the end of each rope staked securely down to the ground; so that, whatsoever way the wind blows, the ropes will stay the tree still in its upright position.

Such new planted trees as are exposed to cattle, should each be well fortified all round the stem with thorn bushes.

The general Planting season, for all sorts of trees, is, autumn and spring, i. e. the autumnal Planting being from the beginning

of the decay of the leaf, in October, until December; though ever-greens may be begun to be transplanted towards the middle or latter end of September, and continued till December aforesaid. And for the spring Planting, February and March is the principal time, but may be continued occasionally until April; and several sorts of tender young ever greens succeed best when planted the beginning of that month.

However, to those persons that have much Planting or other business in hand, I would observe, that Planting need not be confined particularly to autumn and spring; for all hardy kinds, both fruit-trees, forest-trees, shrubs, &c. may be planted occasionally, almost any time, in open weather, from October till March, especially in all moderately dry soils, with good success.

Planting, however, forward in autumn, is of some advantage, as the trees will have time to root more firmly, ready for the ensuing spring shoot, as well as be able to stand the drought of spring and summer somewhat better than those planted later.

But in very humid soils, where water is apt to follow the spade in winter, it is eligible always to plant forward in autumn, or not till spring; but rather principally the last mentioned season, toward the latter end of February, or in March.

Farther Observations, particularly in Planting herbaceous Plants.

In preparing to plant herbaceous fibrous-rooted plants, our first principal care is to remove them, with good roots: young seedlings, &c. especially require particular care in drawing them with proper roots. When they are to be taken all clean up, they may be readily loosened and raised out of the earth with some instrument, with all their fibres entire; but when they are only to be thinned, they do not admit of this, because it would disturb the remaining plants, so must be drawn out by hand carefully, with as much root as possible.

Many sorts of fibrous-rooted plants, however, being so hardy, and apt to grow, that if taken up almost any how, with a little root, they will often strike: it is nevertheless advisable to use care in drawing all sorts for Planting, with tolerable roots, as they will in proportion make more progress in their future growth. And as to any trimming preparatory to Planting, very little is wanted, only

nly in some sorts, just shortening very long naked spindly roots, and trimming any straggling fibres; though in numbers of plants of this tribe hardly any trimming at all is required, neither in root nor top; all of which however you will be able to regulate according to observation, agreeable to the hints here exhibited, and in the culture of the respective articles.

The most commodious and expeditious mode of Planting herbaceous seedlings, slips, offsets, cuttings, &c. is by dibble, as already observed in *Planting by Dibble*; and for such as have been previously pricked out in nursery-rows, many sorts may be drawn with little balls, when required, and holed-in with a trowel, especially numbers of the choicest flowery tribe; but almost all sorts of pricked-out herbaceous fibrous-rooted plants may either be drawn with full roots, and planted by dibble, or with balls of earth, and holed in by trowel, as shall seem most convenient according to the nature of the plants.

Many sorts of fibrous-rooted plants may be planted out at once, where they are finally to remain, particularly all long spindly-rooted kinds; likewise numerous others of the more fibrey-rooted sorts may also be planted out finally from the seed-bed, provided the ground is ready for their reception; yet I would observe when the ground is not ready to receive them for some considerable time, it will be eligible to thin-out a quantity from the seed-bed, and prick them in nursery rows five or six inches asunder, to remain a month or six weeks or longer, till the ground is ready for their reception, whereby they will acquire good roots, and a robust firm growth, in order for final transplantation; whereas when they all remain long in the seed-bed, they by standing so close, draw each other up very slender and weak, and never make near so good plants as those previously thinned and pricked out at small distances; which, after growing a month or two in nursery rows, will all readily rise with full roots for final Planting, and many sorts also with good balls of earth where necessary, which may be more particularly requisite to some of the choice, flowery tribe.

The season for Planting most herbaceous fibrous-rooted plants is any time in spring, summer, and autumn, according as they may be required for different purposes, as is always hinted in the culture of the various sorts; and many hardy kinds even in winter, in mild open weather, when occasionally wanted; for most of this tribe of plants rea-

dily and expeditiously take root at almost any season, in mild weather; chusing generally moist weather in spring and summer, but especially from April until September; and chiefly dry weather for winter Planting: observing likewise in the spring and summer Planting, it is proper always to give a moderate watering as soon as planted, but especially in summer, unless it should happen to rain hard enough to descend to the roots; otherwise a little water to settle the earth close to the roots is of very essential service.

As to Planting herbaceous bulbous-rooted plants, such as hyacinths, narcissus, tulips, and all others of the bulbous tribe, they ought never to be removed but only in summer, when their stalks, leaves, and fibres of the bulbs decay; for these parts of bulbous plants always decay annually in summer, soon after they have flowered and ripened seeds; but the bulbs themselves are perpetuated; so that the above period is the time either to plant out seedlings of these sorts previously into nursery-beds for two or three years or more, to acquire a proper age and size for flowering, then transplanted finally: it is also the proper period for transplanting full-grown bulbs, either from one place to another directly, or take them up to keep for autumn and spring Planting.

All bulbous-rooted plants taken up at the above time of the decay of the stalks, leaves, and fibres, may either be planted again directly, or kept till September, October, or November, and then planted; which for the choicest sorts is the most eligible practice, as observed in their culture: and in order to have a late bloom a few may also be retained out of ground till spring, about January or February; but plant the principal always in autumn, about October and November.

Bulbous plants are planted two or three different ways, as by dibble, by drilling-in, and by bedding in. See each of these methods as exhibited separately under this article PLANTING.

Chuse always dry weather for Planting most kinds of bulbs, especially all the choice kinds.

PLATANUS, Plane Tree.

This genus consists of lofty deciduous trees, of high repute for their singularly beautiful growth and luxuriant foliage; being delightful trees for all ornamental plantations, and for affording shades; also as forest or timber-trees, they growing remarkably strait to a considerable height and magnitude; adorned with

with very large simple, palmated and lobated leaves, from six to twelve or fourteen inches broad, but very small monoecious flowers, collected into close globular heads, succeeded by numerous seeds, digested into large round rough balls.

Class and order, *Monoecia Polyandria*.

Characters.] CALIX, male and female, very small flowers; apart on the same plant, the male florets digested into globular katkins, having very small cups; and females collected into a large roundish ball, having very small scaly calices. COROLLA in the males is scarcely discernible, and in the females each floret having many small concave petals. STAMINA, numerous, small, oblong, coloured filaments, having four-cornered antheræ. PISTILLUM, several subulated germina, having subulated styles, and recurved stigmas. PERICARPIUM, none, numerous roundish seeds, surrounded with down, and collected into round hard balls.

There are only two real species; which, however comprise some varieties, all of which are deciduous, and of hardy growth.

The species are,

¹PLATANUS *Orientalis*.

Oriental or Eastern Plane Tree.] Rises with a very straight, smooth, branching stem, to a great height; palmated leaves, six or eight inches long, and as much broad, divided into five large segments, having the side ones cut into two smaller, green above, and pale underneath; and long pendulous pedunculi, each sustaining several round heads of close-fitting, very small flowers; succeeded by numerous downy seeds, collected into round, rough, hard balls.

It is a native of Asia, and many parts of the East, and grows in great plenty in the Levant.

²PLATANUS *Occidentales*.

Occidental or Western Plane Tree.] Rises with a straight smooth stem, to a great height, branching widely around; lobated leaves, seven or eight inches long, and from nine or ten, to twelve or fourteen broad, divided into three large lobes; and very small flowers, collected into round heads, succeeded by round, rough, balls of seed.

It is a native of Virginia, and other parts of North America; where it attains an enormous size, and is remarkable for having its stem all of an equal girth for a considerable length; and we have an account of some trees being eight or nine yards in circumference,

and when felled, afforded twenty loads of wood.

Varieties of these two species, are,

Spanish or middle Plane Tree.] Having remarkably large leaves of three or five narrower segments.

Maple-leaved Plane Tree.] Having smallest leaves, somewhat lobated into five segments; resembling the maple-tree leaf.

All these elegant trees are of hardy temperature; so as to prosper here in any common soil, and exposure in our open plantations, &c. and are some of the most desirable trees of the deciduous tribe; were in singular esteem among the ancients of the East, for their extraordinary beauty and delightful shade they afforded, by their noble foliage.

The leaves commonly expand in May, and fall off early in autumn; and the flowers appear in spring, a little before the leaves, being succeeded by seeds, which, in fine seasons, frequently ripen here in September.

As to the uses of these fine trees in gardening; they have singular merit for all ornamental plantations; their straight growth, regular branching heads, and lofty stature they attain, together with the extraordinary breadth of their luxuriant leaves, render them extremely desirable furniture to adorn avenues, lawns, parks, and woods; some disposed in ranges; some as single standards; others in clumps; some in groves, &c. and are most excellent for shade; for it is observable, that no tree is better calculated to defend us from the heat of the sun in summer, by its noble spreading foliage, and to admit the sun's rays more freely in winter, on account of the distance of its branches, which is always in proportion to the size of the leaves.

They may also be employed in the collection of forest-trees, in woods, to grow up to timber, in which they will also prove advantageous in time.

In short, these noble trees claim the esteem of every one concerned in plantations of every kind; but more particularly in extensive works, where they may be so variously disposed, as to have a charming effect.

Their Propagation.

The propagation of these trees, is by seed, layers, and cuttings.

By Seed.—The seeds frequently ripen in these parts, and are also procured from other countries, and may be obtained of the nurserymen, or seedsmen; observing, the best season for sowing them is autumn, if they can be then possibly procured. Choosing a somewhat shady moist soil; and having dug the ground, and raked it fine, form it into four-foot wide beds, and either scatter the seeds evenly on the surface, and rake them in, or, previously with the back of a rake, turn the earth off the surface near half an inch deep into the alleys; then sow the seed, and directly, with the rake turned the proper way, draw the earth evenly over the seeds, and trim the surface smooth; many of the plants will rise in spring, and probably may not till the spring following. When they are one or two years old, plant them out in nursery rows, two or three feet asunder, and about half that distance in the lines; here to remain till of a proper size for final transplantation.

By Layers.—This method of propagation is very commonly practised in the nurseries, in default of seed, and by which they most readily grow; for which purpose, some stout plants for stools must be planted, which in a year after must be headed down near the bottom, that they may throw out many shoots near the ground, convenient for laying; which, in the autumn after they are produced, lay by for slit-laying; and by autumn after, they will be well rooted, and form plants two or three feet high, so may be separated, and planted in nursery rows, like the seedlings.

By Cuttings.—All the sorts will take tolerably by cutting off the strong young shoots; but the *Platanus Occidentalis* more freely than the Oriental kind. Autumn is the best season; as soon as the leaf falls, choosing strong young shoots, and plant them in a moist soil; many of them will grow, and make tolerable plants by next autumn.

It should be remarked, that in order to continue the distinction of the varieties more effectually, they should be propagated either by layers or cuttings: for when raised from seed, those of the respective species generally vary.

PLEASURE-GARDEN, or Pleasure-ground.

The district commonly called the Pleasure-ground, may be said to comprehend all ornamental compartments, or divisions of

ground and plantation, surrounding a noble site, consisting of lawns, plantations of trees and shrubs, flower compartments, walks, pieces of water, &c. whether situated wholly within the space generally considered as the Pleasure-garden, or extended over ha-ha's to the adjacent fields, parks, paddocks, or other out-grounds.

In designs for a Pleasure-ground, according to modern improvements, consulting rural disposition, in imitation of nature, all too formal works being almost abolished, such as long straight walks, regular interfections, square grass plots, corresponding parterres, quadrangular and angular spaces, inclosed with high clipped hedges, &c. and other uniformities, as in ancient designs; and instead of which, consists now of rural open spaces of grass ground, of irregular dimensions, and winding walks, all bounded with plantations of trees, shrubs, and flowers, in various irregular clumps, and other compartments, exhibited in a variety of curves, projections, openings, and closings, in imitation of a natural assemblage; not forming inclosures of hedges, &c. but having all the various plantations open to the walks and lawns; for example: a spacious open lawn, of grass ground, being generally first presented immediately on the front of the mansion, or main habitation, having each side embellished with plantations of shrubbery, groves, thickets, &c. in clumps and other compartments, in irregular curves, and projections, towards the lawn, &c. with breaks or opens of grass spaces at intervals, between the plantation; together with serpentine gravel-walks, winding under the shade of the trees; irregular plantations, being also carried round next the outer boundary of the ground, in various openings and closings, having gravel-walks, winding through them, for shady and private walking; and in the interior divisions of the ground is exhibited serpentine winding walks, and elegant grass opens, arranging various ways, all bordered with shrubberies, and other tree and shrub plantations, flower compartments, &c. disposed in a variety of irregular forms and dimensions, in easy bendings, concaves, projections, and straight ranges, occasionally; with intervening breaks or opens of grass ground, arranging irregularly between the compartments of plantations, &c. both to promote rural diversity, and for communication and prospect to the different divi-

divisions; all the plantations being so artfully arranged, as gradually to discover new scenes, each furnishing fresh variety, both in the form of the design in different parts, as well as in the disposition of the various trees, shrubs, and flowers, and other ornaments and diversities.

So that in designs for a Pleasure-ground, according to modern gardening, a tract of ground of any considerable extent may have the prospect varied and diversified exceedingly, in a beautiful representation of art and nature, as that in passing from one compartment to another, still new varieties present themselves in the most agreeable manner; and even if the figure of the ground is irregular, and its surface have many inequalities, in risings and fallings, and other irregularities; the whole may be improved without any great trouble of squaring and leveling, for by humouring the natural form, may cause even the very irregularities to conceal their natural deformities, and carry along with them an air of diversity and novelty.

In these rural works, however, we should not abolish entirely all appearance of art and uniformity; for these, when properly applied, gives an additional beauty and peculiar grace to all our natural productions, and sets nature in the fairest and most advantageous light.

But some of our modern Pleasure-gardens, in which rural design is copied to an extreme, are often very barren of variety and entertainment, [as they frequently consist only of an extensive grass lawn, like a great field, having a running plantation of trees and shrubs all round, just broad enough to admit of a gravel-walk, winding through it in the serpentine way, in many short twists and turns, and bordering at every turn alternately upon the outward fence and the lawn; which are continually obtruded upon the sight, exhibiting the same prospect over and over, without the least variation, so as that after having traversed the walks all round this sort of Pleasure-garden, we find no more variety or entertainment than at our first entrance, for the whole having presented itself at once at the first view; and we might often see as good a garden, sometimes in a common field, that is bordered with any kind of plantation.

Therefore, in laying out a Pleasure-garden, the designer ought to take particular care that the whole extent of his garden, be not taken in at one view; only exhibiting at

first a large open lawn, or other spacious open compartment, or grand walk, &c. terminated on each side with plantations of curious trees, shrubs, and flowers, in compartments, exhibiting only some opens at intervals; and behind these have compartments of the like plantations, with grass opens, gravel-walks, water, and other ornaments; so that a spectator will be agreeably surprised to find what terminated his prospect, was an introduction to new beauties and variety.

But it is impossible to exhibit any regular directions for planning a Pleasure-garden, agreeable to the prevailing modern design in imitation of nature aforesaid; as the plan may be varied exceedingly, according to the natural figure, position, and situation of the ground and taste of the designer; so we can only give some general hints.

General Sketch of the Design.

Take, however, the following general sketch, which may be varied according to the situation and extent of the ground.

With respect to the situation; this must consequently be immediately contiguous to the main house, whether high or low situated; remarking, however, that a somewhat elevated situation, or the side or summit of some very moderate rising ground, is always the most eligible on which to erect the chief habitation, arranging the Pleasure-garden accordingly; such an exposure being the most desirable, both for the beauty of the prospect, and healthfulness of the air; a low level situation, neither affording due prospect of the garden, nor adjacent country, besides being liable to unwholesome dampness, and sometimes inundation in winter: there are, however, many level situations, forming plains or flats, that possess great advantages both of soil and prospect, and the beauties of water, without too copious moisture; there are also sometimes large tracts of ground, consisting both of low and high situations, as level plains, hollows, eminences, and declivities, and other inequalities, which may be so improved, as to make a most desirable spot for a Pleasure-garden, as the scene may be varied in the most beautiful manner imaginable. However, the choice of situation and scope of ground is not always attainable, so every one will regulate his plan in the most commodious manner possible, agreeable to the above hints.

The extent of a Pleasure-Ground may be various

various, according to that of the estate or premises, and of the quality and fortune, &c. of the owner; so may be from even a quarter or half an acre, to thirty or forty or more.

The ground should previously be fenced, which may be occasionally a wall, paling, or hedge, or some of each sort, as may be convenient, and in some parts a fosse or ha-ha, where necessary to extend the prospect, either at the termination of a lawn, walk, or avenue; observing, the close fences should generally be concealed within side, particularly the wall and paling fences, by a range of close plantation, unless where the wall may be wanted for the culture of wall-fruit. But sometimes when a Pleasure-ground adjoins to a fine park, paddock, or any agreeable prospect, the boundary fence on that side is often either a low hedge, or a ha-ha; but many prefer the latter, especially at the termination of any spacious open, both to extend the prospect more effectually, and give the garden an air of greater extent than it really has, at a distance, the ha-ha being sunk, nothing like a fence appears, so that the adjacent park, fields, &c. appear to be connected with the garden. See WALLS, HEDGES, FOSSE, &c.

But with respect to the arrangement of the several divisions, the following general sketches are on a supposition of a considerable tract of ground; and if the plat of ground is small, a greater simplicity of design must be observed in proportion.

First, a noble open lawn of grass ground, is extended on one of the principal fronts of the mansion or main house, directed either towards the open fields, park, or adjacent country, or towards the garden, if the situation requires it; or may be extended a little more or less each way, according as the situation and extent of ground may admit, or require; but, if possible, always considerably the most extensive on the principal front; and should be considerably wider than the house, if possible, and twice as long as broad at least; or if the scope of ground admits it, may even be extended in length, as far as the extreme boundary of the garden: or carried over ha-ha's, to the adjacent park or pasture-grounds, &c. widening gradually in irregular windings, from the house outward; having each side bounded by various plantations of trees, shrubs, and flowers; in groves, clumps, thickets, and other elegant compartments, exhibited in a variety of rural forms, by various

irregular, concave, and convex curves, and projections, to break all appearance of too stiff uniformity; introducing also between the plantations at intervals, breaks, or opens, of grass-ground, communicating with the lawn and internal divisions, in some places widely spread, in others more contracted; leaving also tracts for serpentine gravel-walks, winding under the shade of the plantations, so conducted as to command views of the lawn, and the interior divisions occasionally; observing, the homeward part of the plantation should be inclined a little toward each wing of the house that company may sooner arrive in the walks of the shrubbery; wilderis, and groves, under the shade and shelter of the trees; but the outward extension on each boundary should widen gradually towards the extreme termination, to give an air of grandeur, and admit of a full prospect from and to the mansion. Each boundary being planted with a choice variety of ornamental trees and shrubs, deciduous, and ever-greens, arranged principally in separate clumps, and other compartments, alternately, some consisting wholly of lofty trees, arranged sometimes in regular groves, and some in groups or clumps, irregularly; other compartments being entirely of the shrub kind; and others consisting of trees, shrubs, and herbaceous perennials together: in all of which, arranging the taller growth backward, and the lower forward, according to their gradation of height; embellishing the fronts with the more curious low flowering shrubs and ever-greens, interspersed with various herbaceous flowering perennials, all open to the lawn; and the termination of the lawn at the farthest extremity, if extended considerable outward to some agreeable prospect, is generally continued open the whole width, by sinking a ha-ha at the limits of the garden, to unite the view with the adjacent pastures, plantations, and the open country, as well as admit of a grand view to and from the mansion. See LAWN.

But sometimes the termination of the lawn, in default of prospect beyond the limits of the garden, or that it is necessary to conceal the garden from the view of persons without, is by a plantation of stately trees, in considerable concave, and convex sweeps. Or small lawns that extend immediately towards the garden, may be terminated by elegant shrubbery clumps, continued to the interior division. However, for considerable lawns,

lawns, extended outward to the utmost verge of the garden, that admit of any tolerable prospect of the adjacent fields, &c. a fosse or ha-ha termination, is the most eligible, in order to continue the prospect. See FOSSE and LAWN.

From the boundary plantation of the lawn, is continued the internal works, in a great variety of rural divisions, in spacious walks and open spaces, bounded by shrubby clumps, wilderness plantations, groves, thickets, &c. all in various elegant, irregular, compartments, as before mentioned, to exhibit a grand rural imitation, diversified in a variety of forms.

In the general arrangement, the great art is to vary the prospect of the different divisions, so as they may variously present an air of novelty, and source of convenience and entertainment.

Around towards the outer boundary fence, is generally arranged a plantation of trees, and shrubs, in various irregular windings and projections next the garden, and broad enough to admit of a serpentine gravel-walk, winding through it all round the garden, under cover of the trees and shrubs, for private and shady walking: varying the plantation in different degrees of thicket and openings occasionally, with here and there breaks and openings, for prospect from the walks to the different parts of the garden and open country; and with circular or concave grass spaces, bordering the walk at intervals for diversity, and as places for seats, &c. under shade of the plantation.

In the more interior parts are exhibited magnificent walks, avenues, and grass openings, some nearly straight, others more or less winding, arranging in different directions; and having each side embellished with plantations, in shrubby clumps, groves of trees, wilderness plantations, thickets, and flower compartments, distributed in various arrangements and distances, admitting intervals of grass ground surrounding and communicating with the various plantation divisions, in some places of considerable extent, in others more or less contracted, according to the distance and arrangement of the several clumps and other compartments of plantation, which should be exhibited in a variety of windings, openings, and closings, from one degree of light and shade to another; introducing also grand openings, at intervals, between the principal districts of plantation, for

views or prospect, &c. and from the main walks and openings, have other smaller walks branching off at due distances, in a winding direction, to places of shade and retirement, amidst the plantation, and for communication from one division to another; exhibiting also opens of different figures and dimensions, surrounded by clumps of trees and shrubs, serving some for recesses, and places of shade, as before said, others for garden edifices, as temples, grottos, rural seats, statues, &c. and sometimes for pieces of water; and if water from some upper spring or head, can be led in a winding course, through the lower parts in gentle meanders, it will have a charming effect; Other internal divisions appear with an air of grandeur and magnificence, by exhibiting a spacious opening of grass ground, bounded by the noblest trees and shrubs, in various elegant clumps, groves, groupes, and straight ranges; and the opening terminated by some fine open prospect, noble pieces of water or an ornamental building; and with gravel-walks, winding through the boundary plantations. Another part shall appear more gay and sprightly, displaying an elegant flower-ground, designed somewhat in the parterre way, in various beds, borders, and other compartments, furnished with the most curious flowers; and the boundary decorated with an arrangement of various clumps, of the most beautiful flowering shrubs, and lively ever-greens, each clump also bordered with a variety of the herbaceous flowery tribe.

Another division sometimes presents a wilderness, in irregular partitions of plantation, having many intervening serpentine walks, both private and open, bending in various directions, by many winding mazes or labyrinths, into openings formed in different parts amidst the plantation, and to a grand one in the center of all; the boundary plantations of this division being generally in close assemblage, with tracts of serpentine walks between, leading in private meanders towards the interior parts; breaking out sometimes into other walks that are open and spacious, both of grass and gravel occasionally, conducted also in serpentine turns, to cause the greater variety, having each side bordered with plantations of trees and shrubs, the tallest behind, the lower growth in front; and from these grand walks, others more narrow and close, branch off at intervals, in various windings, in some places being

ing closely bordered with tall trees, to effect a gloominess and perfect shade; the different walks leading now and then into circular openings of grass in different parts, each being surrounded with plantations as aforesaid; making also the principal walks terminate in a grand opening in the centre of the wilderness, in which may be some ornamental edifice, or fine piece of water, &c. furnishing all the plantation compartments, with a good variety of trees and shrubs; the deciduous and ever-green kinds principally in separate clumps, or quarters, interspersed with various wood flowers promiscuously, placing the more curious kinds of shrubs and flowers towards the fronts next the walks and openings, conspicuous to view. See WILDERNESS.

Straight ranges of the most stately trees, are sometimes arranged on grass ground in different parts, in contrast with irregular plantations; and produce a most agreeable effect, which though prohibited in many modern designs, always exhibit an air of grandeur; being arranged sometimes in single rows, others double, or two ranges at certain distances, forming a grand walk or avenue; in other parts, several ranges together in the manner of groves: all of which being arranged on grass ground occasionally in different situation, will have a grand and solemn appearance. See AVENUE and GROVES.

Sometimes an outward division discovers a close plantation of trees, like a thicket of woodland, arranged in irregular assemblage, mostly close and gloomy, resembling the internal arrangement of a wood; sometimes exhibiting sudden transitions of light and shade, by openings and closings, having serpentine walks winding through every part, and sometimes leading to openings in the midst of the plantation. Others breaking out suddenly from the thicket into open prospects of the other divisions; having all the walks bordered with flowering shrubs, hardy climbers, and various wood flowers that prosper under shade, and many common hardy shrubs, and herbaceous plants scattered promiscuously among the trees, to form more or less thicket, and cause diversity in the manner of a natural wood.

In other parts are sometimes discovered eminences, or rising grounds, as an high terrace, mount, steep, declivity, or other elevated situation, having the sides covered with grass and compartments of plantation; and

walks leading under the shade of trees by easy ascents, to the top, where is presented an extensive prospect of the adjacent fields, cottages, hamlets, and country around, as well as afford a fresh and cooling air in summer.

Regular compartments and figures, in various forms, are also sometimes introduced in some extensive grounds, for variety, in contrast with the irregular works, and still to preserve some appearance of the remains of ancient gardening; such as straight walks, verged with borders of flowers, &c. regular parterres, in flower borders; square spaces, circles, and octagons, &c. inclosed with clipped hedges: hedge-work, formed into various architectural devices; detached yews, and other ever-greens, formed into pyramids and other regular figures; regular grass slopes, formed on the side of some declivity or rising ground. Bosquets of trees, surrounded with low ever-green hedges; straight avenues of trees in ranges, regular terraces, &c. a little of each being judiciously disposed in different situations, may prove an agreeable variety, by diversifying the scene, in contrast with the rural work aforesaid.

Sometimes a bleak declivity, or some rough hollow ground or vale, is made to exhibit a wild or uncultivated scene, by arranging some scattered clumps of trees, in the most irregular assemblage; the intervals or spaces between being rough grass ground, and here and there tufts of shrubby bushes, with sometimes a gentle rill of water, winding along the bottom of the declivity, or twisting its course through the vale.

Towards the lower parts of the garden, pieces of water are always exhibited where possible, in the most conspicuous points of view contiguous to the termination of the main lawn, or other spacious open, representing sometimes a basin, lake, &c. and sometimes a natural river, winding its course through different divisions, and its termination concealed by a curious turn, making it appear to lose itself in the adjacent plantations. See WATER.

With respect to the walks, these may be both of gravel, sand, and grass, but principally gravel for common walking; and grass for occasional walking in the heat of summer, which in dry hot weather may be more agreeable than the hard gravel-walks: therefore some of each sort is proper both for convenience and variety.

Gravel-

Gravel-walks, however, should lead all round the garden and into the principal internal divisions, so as to have dry and firm walking at all times of the year; when the grass is too damp, as in winter and all wet weather.

These gravel-walks should be of proportional width, in different parts, according to the extent of the garden.

As to the distribution of gravel-walks:—first a magnificent one, from fifteen to twenty or thirty feet wide, should range immediately close and parallel with the front of the house, and be conducted directly across the lawn into the nearest shrubbery and general plantation; where each side being verged with spaces of grass ground, and shrubbery clumps, &c. from this main gravel-walk, other smaller ones, from five to ten or twelve feet wide, should branch off at proper intervals, directed in the serpentine way; some leading through the outer boundary plantation, as already hinted; others into the central divisions; and others carried along the boundary plantation of the main lawn; all of which walks being conducted through and between the different principal plantation, is highly requisite, both for the convenience of shade, and retirement occasionally, as well as to enjoy the variety of the different sorts of trees, shrubs, and flowers, variously presenting themselves at different turnings: for the walks having various irregular twistings and windings, discovering only a moderate length at once, every turning produces new varieties; and should likewise be so contrived, as at proper intervals to discover openings for prospect into different principal divisions of the garden; having in some places the plantation of trees, shrubs, and flowers, bordering close upon the walks; in other parts, have on one side of the walks considerable grass spaces, running into the adjacent plantation, in one or more concave curves, to form the greater diversity.

And in some places the windings of the walks should be gradual and moderate; in others exhibit sudden turns, and grand sweeps, each turning exhibiting sometimes a magnificent projection in the plantation, others some spacious opening, bordered with curious plants; other parts a close thicket, which sometimes may seem to terminate the walk, when by a sudden turn it breaks out all at once into some grand open division, spacious open walk, an avenue, or elegant piece of

water, open grove, &c. And in other parts a walk sometimes suddenly divides into two or three divisions, leading different ways, in bold sweeps, each separation being formed by a projecting clump of shrubbery work, or group of trees, &c. and each division of the walk is conducted by curious serpentine turns, as soon to be concealed from the other; by the intervening plantation compartments.

All these gravel-walks should be laid with the best gravel, six or eight inches deep at least; but if more the better. See GRAVEL and GRAVEL-WALKS.

Grass-walks may be considered as all the open grass spaces, whether formed in the manner of walks, or as breaks or divisions between the various plantations, all of which serving both for communication to different parts, and to render the ground more rurally ornamental, and for occasional walking in dry weather in summer; but some tracts of considerable width and length, formed into grass-walks, leading to different divisions, having each side bounded with clumps of trees, shrubs, and flowers, gives an air of grandeur to the garden, allotting smaller breaks, or open of grass, branching off between, the plantation compartments, as formerly mentioned.

The grass ground of this garden may be formed, either by sowing grass-seed, or by laying it with turf, cut from some common or downs; but in very extensive works turfing the whole would be a great expence; therefore seed is the most eligible for the principal spaces in very large gardens. For the method however of forming grass-ground, both by seed and turfing, and for keeping the grass in order, see GRASS.

Water being so ornamental in all garden designs, no pains should be spared to introduce it where possible; but where it admits of a constant running stream, from some adjacent upper spring, its beauties may be rendered admirably fine, as it may be conducted in meanders through the garden; so as to effect a beautiful assemblage of verdure and water together; and if it should be continued to any considerable length, one or more ornamental Chinese bridges may be carried over at convenient places, which will have a beautiful effect, and serve for communication with the opposite divisions, on each side of the rivulet.

Cascades, and other water-falls, have also a fine effect, where there are a constant plentiful stream, and the situation proper to give the

the water a due fall, from a high to a lower part, upon a parcel of rugged stones, to encrease the noise, and break and disperse the water.

In some grounds, by their natural situation, water may be obtained at a moderate expence; as sometimes a contiguous vale, or meadow, bounded by rising ground, and with a brook or rivulet constantly running through it, may be easily thrown into the most agreeable form: and sometimes large springs issuing from an upper ground, and running down a moderate descent between two rising grounds, to some vale below; it may be contrived, by making proper heads at distances, to form several lakes strung together, as it were, one above another, up to the beginning of the spring; each head may form a beautiful water-fall, or cascade; having the rising grounds on each side embellished with clumps of plantation.

Lakes and artificial rivers may also be contrived in a flat or level ground, where there are any contiguous brooks that can be conducted to supply them with water.

All pieces of water should generally be contrived in a natural imitation, as much as the situation will admit; and its boundary on all sides should be grass ground to some considerable width, sloped off as easy as possible, corresponding with the other adjacent grass ground, to admit of a prospect of the water at some distance. See WATER.

The various compartments of ground intended for the different plantations, should be digged or trenched for the reception of the plants; particularly for all plantations of shrubbery, wilderness quarters, flower compartments, &c. and the ground should be raised somewhat above the common level, in a gentle swell; especially all detached compartments; such as shrubbery clumps, and flower partitions, and most other detached compartments of ground for any kind of ornamental plantation in gardens, should generally be raised in a moderate rounding swell, gradually from each side to the middle; or for any continued side plantation it may be raised in a gentle slope: for the swelling and sloping figure always strikes the eye the most agreeably, as well as shew the plants to the best advantage.

But where intended to have groves of stately trees, or any straight ranges of trees, either singly, or double lines, forming a walk or avenue; it is most in character to dispose them all on grass ground; in which they will appear the most rural and beautiful.

Likewise elegant ornamental trees, both as single standards, and in detached groups, or clumps, appear the most beautiful when disposed on openings of grass ground.

However, for all kinds of shrubbery and wilderness plantations, &c. the compartments should generally be dug ground, as before observed.

All the plantation compartments of shrubbery, wilderness, &c. should be planted with some considerable variety of different sorts of trees, shrubs, and flowers, artfully disposed in irregular arrangement; the taller behind, the lowest forward, and the different sorts so intermixed, as to display a beautiful diversity of foliage and flowers, disposing the more curious kinds contiguous to the principal walks and lawns.

For a list of the different sorts of trees, shrubs, &c. proper for embellishing the several divisions, See DECIDUOUS TREES, and EVERGREENS.

Observing, that as the trees and shrubs are of two different tribes, deciduous, and evergreen kinds; those of each tribe should be mostly planted in separate clumps, in which they will effect the most agreeable variety; and in some places may exhibit clumps composed of both sorts, to cause the greater diversity; and many of the most conspicuous deciduous compartments may be embellished towards the fronts, with some showy evergreens thinly dispersed; which will appear ornamental and lively in winter, when the deciduous plants are destitute of leaves. In planting the several shrubbery clumps, &c. some may be entirely of trees; but the greater part an assemblage of trees and shrubs together; some entirely of the low shrub kind, in different situations, between the clumps, of larger growth; likewise should intersperse most of the shrubbery and wilderness compartments with a variety of hardy herbaceous flowery plants, of different growths; having also here and there clumps entirely of herbaceous perennials: the distribution or arrangement of the clumps, and other divisions of the different kinds, both trees, shrubs, and flowers, should be so diversly, as to exhibit a proper contrast, and a curious variation of the general scene.

And in the disposing the various trees, shrubs, and other plants in their respective compartments, observe, somewhat in the quincunx way, not exactly so, nor in regular ranges; and for the most part, place the tallest

tallest towards the middle or back part, and the lower forward towards the front, according to their natural stature of growth; observing also to intermix the different sorts in each clump, &c in such order, as to display a diversity of different foliage and flowers, as aforesaid, as well as exhibit a conspicuous variety. Likewise placing the various sorts at such proportionable distances and dispositions, according to their various growths as each may have full scope to spread its head; and so as the prospect of one may be no interruption or impediment to the growth and appearance of another, but all so judiciously arranged as to set off each other and appear to proper advantage from the contiguous lawns, walks, and other divisions. See PLANTATION.

Observe, in planting any continued or running plantation where shady walks are designed, that particular care is requisite in arranging a due share of the taller trees and shrubs nearer the walks and in such order as to produce the desired effect, particularly in the continued plantation of shrubbery work around the outward boundary, and on the boundary of the lawn and other running plantations, through which serpentine walks are carried: planting many tall-growing trees and shrubs more or less towards the walk in such arrangement as to produce proper shade, shelter, and private walking, with occasional openings and closings at intervals, as hath been already observed; interspersing also many smaller shrubs and hardy herbaceous plants between the larger growths; disposing the whole so judiciously as to afford also a source of variety in the excursion of the walks.

These plantations for shady walks are highly necessary to retire to occasionally, for shelter from the injuries of the weather: they afford shade from the scorching rays of the summer's sun, shelter from tempestuous winds and cold blasts, and for private walking when required. But where very close and gloomy shade is required in any particular parts for diversity, some tall trees should be arranged close along the verge of the walks backed with others, and a variety of hardy shrubs, in such order as to produce the proper effect.

In planting groves and avenues, they should be composed principally of the tree kind, and such as are of straight and handsome growth, with the most branchy, full, regular heads, and may be both of the deciduous

and ever-green tribe; but generally arranged separately; which, for groves and avenues, should always be in some considerable open space, formed into grass ground, either before or after planting the trees; and in planting the groves, it is most eligible to arrange the trees in lines, in some places straight rows, others in gentle bendings, or easy sweeps, having the rows at some considerable distance that the trees may have full scope to display their branchy heads regularly around; and in some places may have close groves to form a more perfect shade. And as to avenues and walks of trees; they may be formed either entirely of deciduous trees, or of ever-greens; but the deciduous kinds are in most estimation for forming fine avenues: however, avenues and grand grass-walks, planted with beautiful ever-green trees, make a fine appearance. In both sorts, the trees are most commonly disposed in straight rows, one on each side of the avenue, though sometimes grand walks of trees may be both in straight lines and in windings, to exhibit the greater variety, planting the trees generally, both in the avenues and walks, at proper distances to have full scope to branch out regularly around and display their beautiful heads. See AVENUES, GROVES, &c.

But thickets may be composed of all sorts of hardy deciduous trees, planted close and promiscuously, and with various common shrubs dispersed between the trees, as underwoods, to exhibit a more or less thicket occasionally in different parts. See THICKET.

Thickets may also be of ever-green trees, particularly of the pine and fir kinds.

Straight rows of beautiful ever-greens, as pines, firs, cypresses, cedars, &c. forming magnificent walks, are very ornamental.

In some open spaces of grass-ground, such as spacious open lawns, or other considerable opens in parks, &c. should dispose some of the most beautiful trees and elegant shrubs detached, both separately as standards or single objects; and in groups or assemblages, from two or three to five or ten or more in different groups or clumps; some irregularly, others in curves, straight lines, &c. for variety, arranging both single standards, and groups a considerable way asunder not to obstruct the prospect, and at such irregular distances as if they had grown there by chance.

It sometimes happens that on the spot or tract of ground which is designed for a Pleasure-

ture-ground are found large old trees of considerable standing, properly situated to be introduced into the design, sometimes in proper assemblage for constituting a grove or a thicket, and some as single standards, groupes, or clumps, &c. which will prove a considerable advantage; and should be preserved with the utmost care, as it would probably require an age or two to form the like with young plantations; and although the trees should stand ever so close, or irregular and straggling, they, with proper address of thinning or regulating where necessary, may be introduced for purposes as above so as to have a fine effect. See GROVES, &c.

A commodious space for a flower-ground distinct from the other divisions as formerly hinted, is most necessary for the culture of the more curious and valuable kinds of flowers.

This principal flower-ground forming a distinct division, exclusive of the other flower compartments distributed in different parts in contrast with the shrubby clumps, &c. should be allotted for a choice collection of the finest kinds of both bulbous and fibrous rooted flowers. The form of this ground may be either square, oblong, or somewhat circular; having the boundary of the division formed by an arrangement of a curious shrubby embellished with a collection of the most beautiful flowering shrubs; and the interior part should be divided into many narrow compartments, either in the manner of a parterre, formed into straight borders, beds, &c. edged with box, see PARTERRE; or divided into plain four-feet-wide beds arranging parallel, having two-feet-wide alleys between bed and bed: in either method having a walk carried all round next the outer boundary, then a border surrounding the whole division, and within this have the various division of beds, &c. as above, raising them all in a rounding manner, highest in the middle, and edge the compartments principally with dwarf-box, and some with thrift and pinks by way of variety, laying the walks and alleys with the finest gravel.

In this division you should deposite all your finest hyacinths, tulips, narcissus, polyanthos-narcissus, jonquils, ranunculus, anemones, and all the other more curious bulbous and tuberous rooted flowers; each sort principally in separate compartments, especially of the choicer kinds; which being necessary both for distinctions sake and for the

convenience of giving them occasional protection from inclement weather: but for particulars, in respect to the sorts, method of planting, and general culture, see the respective articles under the proper *genera*.

Likewise in this division should be planted a curious collection of the finest fibrous-rooted flowery plants, as carnations, polyanthuses, auriculas, and many other curious sorts, arranging some of the most valuable in beds separately: others may be dispersed in different compartments forming an assemblage of various sorts.

In other compartments may exhibit a variety of all sorts, both bulbous and fibrous-rooted kinds.

In spacious Pleasure-grounds, various buildings and erections are introduced as ornaments to particular departments. For instance, light ornamental buildings, as temples, a banquetting-house, bowers, alcoves, grottos, rural seats, cottages, fountains, obelisks, statues, and other edifices and devices, are often introduced in different parts in openings between and contiguous to the divisions of plantation and termination of grand walks, &c. Some of these kinds of ornaments however being expensive, are rather sparingly introduced; sometimes a temple is presented at the termination of a grand walk or opening, or sometimes a temple, banquetting-house, or bower is stationed in the centre of some spacious opening of grass ground in the internal divisions; other parts present alcoves, bowers, grottos, rural seats, &c. at the termination of different walks or openings and with rural seats placed in different opens or breaks by the sides of long walks, under shade of trees, for places of rest, &c. Fountains and statues are generally introduced in the middle of spacious opens; statues are also often stationed at the termination of particular walks; sometimes in woods, thickets, and recesses, upon mounts, terraces, and other stations, according to what they are to represent.

Sometimes also there are exhibited root-houses, rock and shell-work, &c. representing hermitages, caves, and the like; being generally stationed in some retired or private situation, and as these kind of buildings being arched or vaulted, they are commonly covered with a coat of earth and turfed with grass, so as to appear like a sort of mount, hillock, or knoll, and planted with some little

little clumps of shrubs, &c. having private walks leading to the entrance.

Likewise in some parts is exhibited artificial rock-work, sometimes contiguous to some grotto, fountain, rural piece of water, &c. and planted with a variety of saxatile plants, or such as grow naturally on rocks and mountains.

Ornamental bridges over artificial rivers, or any rural pieces of water in some magnificent opening, so as to admit of a prospect thereof at some distance or from the habitation, have a fine effect.

General Culture of the Ground.

With respect to the general culture of this ground, neatness must be ever observed in every part; the walks, lawns, shrubbery, clumps, &c. and the several compartments of trees, shrubs, and flowers, kept duly furnished with a proper stock of the various plants.

The gravel-walks must always be kept free from weeds and all sorts of litter, and should be rolled twice or three times a week in summer, particularly the principal walks, but never less than once a week; previously trim the edges close when necessary, especially if verged with grass-ground; pulling out all weeds, and lightly sweeping off all loose litter: and then roll them well with an iron or stone roller. The rolling in summer should be occasionally performed immediately after showers of rain, particularly the first after any continuance of very dry weather, to settle all the loose parts compact and smooth: in winter, the rolling should also be occasionally performed; observing, it is improper to break up the walks in that season in rough ridges as often practised, to remain in that unsightly manner till spring, whereby the walks are rendered useless at a time when there is hardly any dry or sound walking upon grass or other parts, besides their having a disagreeable slovingly appearance; let the walks therefore remain undisturbed, at least till spring, when, if the surface is foul, or mossy, they may be broken up, and turned the surface to the bottom, and the bottom to the top; directly tread, rake, and roll them smooth, proper for walking on. See GRAVEL WALKS.

All the principal grass lawns and walks within the limits of the Pleasure-garden should also be kept perfectly neat by frequent mowing in summer, to keep the grass short, close, and fine, like a fine pasture down or

common; likewise poleing it frequently with a long pole to scatter the worm-casts of earth which so greatly deface all grass; and give also occasional rolling both to clean up the scattered worm-casts to make the surface clean, and to render it firm and smooth. The poleing and rolling should generally be performed the day previous to mowing, whereby the mowing will be more easily, expeditiously, and effectually performed; observing the mowing will be necessary about once a week or fortnight, from March or April until September or October, choosing always dewy mornings, or moist weather for this work, being careful to have each mowing performed with an even hand, not to score or leave the mark of the scythe at each stroke, which has a most disagreeable appearance; and directly after mowing sweep up all the swarths of grass as clean as possible into heaps and carry them away. See GRASS.

Where numerous wild daisies deface the grass in May or June as is sometimes the case, even often in a day after mowing, they may be headed down at a great rate with an old broad sword fixed in the end of a long pole.

Likewise keep all grass-ground clean from litter, such as fallen leaves of trees, &c. which may be expeditiously effected by a light broom or besom on a long handle. See BROOMS.

The edges of all principal grass-walks and those of grass-ground, next gravel-walks in particular, should always be kept close and even; which once a year in spring, when the walks are to be turned and new laid, may be previously cut even slightly with an edging iron: after this, during the summer, they may be trimmed even occasionally as the grass grows, either with the points of the garden-shears, with a pair of sheep-shears, or with the point of a knife; for if these edges are not kept close and even they have a slovenly appearance.

The shrubbery and other plantations of trees and shrubs, should generally all be suffered to take their own natural growth, and branch out into full heads, only just giving a little occasional trimming to any very irregular growths, such as retrenching or reducing any very luxuriant rude shoots, or considerable ramblers, running wildly from all the other branches and all dead wood: likewise, for the general part, keep all the shrubs from interfering or intangling with one another, by shortening occasionally any straggling

straggling or rambling interfering branches, so as the head of each shrub may appear distinct, in which they will shew themselves to proper advantage, and effect a more agreeable variety.

Observing, the best season for performing those occasional regulations of pruning is, for the deciduous kinds, any time in winter or spring when destitute of leaves, especially for any general trimming; but for the ever-green kinds, the most eligible season to give any necessary pruning, is either autumn or in spring, about March or April, especially when any considerable trimming may be occasionally required, as if performed in winter or very sharp weather, that by laying the more interior tender parts more immediately open to the cold, it often injures the leaves and young shoots; however, where only a little retrenching or shortening here and there a rambling shoot is necessary, it may be performed almost any time to any of the sorts: but remarking both of the deciduous and ever-green kinds, that when any general trimming is occasionally required throughout the different plantations, it is highly proper to perform it at the above-mentioned seasons, previous to giving the annual digging to the ground between the shrubs, &c. as directed below.

When close thickets however are intended, no regulation or thinning need be observed, but let the various sorts run promiscuously.

The ground of the shrubbery plantation and wilderness quarters should generally be digged every year, in winter or spring; previously giving the shrubs any necessary trimming as above observed; then dig the ground between neatly, one spade deep, trimming off any rambling suckers or spawn from the roots, leaving the surface of the ground level and smooth: this operation gives health and vigour to the plants, kills weeds, and gives the place an air of culture, and a lively neat appearance.

After this general digging the clumps, &c. the ground must be kept clean from weeds all summer, by occasional hoeing in dry weather, which with a Dutch scuffing-hoe, may be expeditiously performed. See HOE and HOEING.

Great care is requisite to support with sticks all such plants as require it, particularly all such of the herbaceous tribe that are liable to be over-turned by the wind, weight of wet,

&c. for there is great merit in preserving all tall plants in an upright posture.

Keep likewise all the flower compartments in neat order by an annual digging, in autumn, winter, or spring; hoeing in summer to destroy weeds; at each hoeing always rake the surface smooth, particularly the principal borders and other compartments: likewise according as the various plants grow up, let such as need support have sticks placed to preserve them upright; and as they have done flowering and their stalks decay, cut them down close, clearing off also all decayed leaves, and other rubbish from time to time as they appear; taking up also the roots of curious bulbous flowers, as their leaves and stalks decay: and in autumn, about October or November, it is proper to give a general dressing by cutting down all remaining decayed stalks, and prepare to dig the ground: observing, if any manure is necessary, this is the time to apply it; so digging the ground neatly one spade deep, and then if any kinds of plants or roots are wanted, plant them now, and finish with a neat raking, that the whole may lie clean and decent during the winter; and in spring stir the ground a little with a hoe or rake, or such as was not digged in autumn or winter, as above advised, must now be done; and finish putting in such plants that were omitted in autumn; then rake the ground smooth that every part may assume a fresh chearful appearance in the spring and summer seasons.

All kinds of hedge-work and trained figures of ever-greens, should be shorn or clipped annually in summer with garden shears; but to keep them perfectly neat, twice every summer is necessary, the first in June, and the second in August or September. See HEDGES.

Also all edgings of box, &c. to walks, borders, and beds, should always be neatly clipped once or twice every year in summer; but to have them extremely neat, they should be clipped twice in that season, *i. e.* in May or early in June, and in August, choosing principally moist weather, if possible, for if cut in very dry hot weather, the leaves change brown and unsightly: the same also happens if clipped in winter, or early in spring, while cold weather and frosty nights prevail, so should cut these edgings principally in summer. See BUXUS, article *Dwarf-box for edgings.*

All other edgings of thrift, pinks, daisies, London-pride, &c. should also be kept cut in on each side, every summer after the flowers are past, to keep them neat, and within due bounds, performing it in moist weather, as observed of the box edgings; likewise edgings of undershrubby aromatics must have the operation of clipping annually performed at sides and top in summer: for all edgings should be kept low, narrow, and regular, otherwise they will appear clumsy and unsightly. See EDGINGS.

For particulars relative to the general culture of the various shrubs and flowers, see their respective genera.

Of ancient Designs.

Designs in ancient gardening for a Pleasure-ground consulted uniformity in every part, exact levels, straight lines, parallels, squares, angles, circles, geometrical figures, &c. all corresponding in the greatest regularity, to effect an exact symmetry and proportion.

Straight walks were every where observed, and all arranged parallel, and crossing one another in regular intersections; generally a grand one of gravel was extended in a straight line immediately from the front of the main house, having each side verged either with a regular straight border of earth, furnished with a variety of flowers, &c. and sometimes having a verge of grass three or four feet wide, then a border embellished as above with various plants; this main walk being often intersected by others at regular distances, so as sometimes to divide the space immediately in the front of the house into four, six, or more equal squares, some of which were sometimes formed into parterres, sometimes only naked grass-plats, or other uniform divisions; and often the whole garden was thus divided by straight, parallel, and intersecting walks into many regular squares and angles, without any variation.

Grand parterres were very commonly presented immediately on the front of the main house, having a grand walk of grass or gravel directly from the house through the middle, or dividing the parterre ground into two divisions. See PARTERRE.

In the more interior parts, large tracts of ground were frequently divided by straight grass walks into many square and angular divisions of wilderness, each division surrounded by tall regular hedges of various kinds of

trees and shrubs, kept in uniform order by an annual sheering or clipping; having the interior part of each quarter planted with trees and shrubs, which however were in a manner concealed by the hedges from persons in the adjacent walks, so that hardly any thing but close hedges, the same thing over again, appeared to view, on each side of the walks; and all the walks generally led into uniform openings of grass, particularly to a grand circle or octagon in the centre.

Frequently there were partitions of regular hedge-work, particularly of ever-greens, surrounding large squares of grass ground, designed as pieces of garden ornaments, being often formed into various uniform devices of rural architecture; such as pilasters, arcades or arches, porticoes, galleries, amphitheatres, pavilions, cabinets, bowers, pediments, niches, and cornices; likewise regular arbors, having the sides formed into arcades, and sometimes the top curiously vaulted; and with various other formal imitations, all performed in hedge-work, which were often so arranged and artfully trained, as to effect an air of grandeur and art, as well as afford an opportunity for the gardener to display his ingenuity in such kind of works. High hedges were also in great repute, as boundaries to grand walks and avenues, sometimes carried up from fifteen or twenty, to thirty or forty feet high; sometimes trained perfectly close from the very bottom to top, others open below a considerable way, and curiously formed into regular arches, &c. all of which sometimes appeared magnificent and ornamental, but were troublesome and expensive to keep in order, on account of their great height: however, all sorts of hedge-work was generally esteemed so ornamental in ancient gardening, that almost every division was surrounded with regular hedges of one sort or other, presenting themselves to view in every part, shutting out all other objects from sight; but in modern designs hedges are rarely admitted; every compartment of plantation being left open to view from the walks and lawns, to have a full prospect of the various trees, shrubs, and flowers, which consequently are more beautiful than ranges of close hedges: but for the sake of variety, a little ornamental hedge-work might still be introduced in some particular parts of the ground. See HEDGES, the article *Internal Hedges*.

Wildernesses were always designed with the greatest uniformity, the ground being divided

vided by walks into many squares and angles, all corresponding, and all the walks straight, and the principal ones all leading to some common centre or opening, such as a circle, octagon, &c. with all the quarters or divisions commonly surrounded with close hedges as before observed, both of the deciduous and ever-green kinds. See WILDERNESS.

Labyrinths of hedge-work, in the manner of a wilderness, also prevailed in many large gardens. See LABYRINTH.

Detached trained figures of ever-greens, as yew, cypress, juniper, holly, box, and various other close-growing ever-green plants, but principally yew, were also very predominant in ancient designs, and generally disposed in regular ranges along the borders and other verges of grand walks; being trained by clipping into various formal shapes, as pyramids, obelisks, columns, &c. in a variety of forms, with a multitude of other formal figures, all placed in the most exact arrangement. Some also were often placed singly in the midst of some circle, octagon, or other open space, and were all kept in order by clipping once or twice every summer, and were considered as great ornaments.

Straight rows of the most beautiful trees forming long avenues and grand walks were in great estimation, which, though not often admitted in modern designs, were formerly considered as great ornaments, and no considerable estate and eminent Pleasure-ground was without several of them; but modern planners rarely introduce straight ranges of trees for avenues or walks, but even often demolish old ones of a century or two standing, as being thought too formal; however, ranges of trees, forming spacious avenues, &c. about extensive grounds, always give an air of grandeur and dignity to the premises.

Regular grass slopes also greatly prevailed in most old gardens, as ornaments to particular divisions; sometimes was formed at the beginning of some rising ground, also sometimes at the termination, and frequently some low ground, canals, and other formal pieces of water, were bounded by a range of regular grass slopes; likewise regular grass slopes formed the sides of terraces and other rising grounds. Moderate grass slopes also often formed a boundary to some open spaces, as a bowling-green, flower-garden, &c. forming a sort of terrace all round, having sometimes a gravel-walk at top; these slopes were al-

ways formed with the greatest regularity and exactness, which in some situations were very ornamental. They were of various dimensions in respect to height, from one foot to ten or twenty high, according to the nature of the situation and purpose they were designed for, in different parts; and some being ranged singly, others double, treble, or several one above another on the side of some considerable rising ground, in a theatrical arrangement.

Regular terraces, either on a natural eminence or of forced ground, were also introduced for ornament, and for the sake of prospect, and of enjoying the fresh air in summer.

But as the above taste in the ancient style of designing gardens, being generally crowded every where with exact uniform divisions and formal figures, some of which being often trifling, and the same thing often prevailing in almost every part, that even gardens of very considerable extent afforded very little variety; and the perpetual shew of stiffness and formality of the same thing over again, together with the numerous surrounding hedges in every division, obtruding constantly upon the sight, obstructing all other objects, that at last they became so disagreeable to persons of taste, they abolished almost all formal works from their gardens, suffering hardly any regular appearance, substituting rural works, in imitation of nature, as already described.

However, for the sake of diversity, some of the more elegant regular works might still be admitted sparingly, in particular divisions, in contrast with the general rural performances, so as in some places to exhibit a grand straight gravel or grass-walk, in others a parterre, and in some places straight rows of the most beautiful trees, forming walks and avenues, and sometimes a range of hedge-work, and here and there a pyramid of yew or other proper ever-greens; and sometimes a regular grass slope, formal terrace, &c. all of which, if judiciously disposed, might assist in diversifying the general scene.

PLENUS Flos, a full or most double flower; a flower having the greatest plenitude or multiplicity of petals, often to the diminution or entire exclusion of the parts of fructification.

Perfectly Full Flowers, whose multiplicity of petals obliterate the generative organs, consequently prove barren, *i. e.* rarely ever producing seed; but mostly all Full Flowers are varieties of singles, which are always the original species; so that the singles and half-doubles only

only produce the seed, and from which both double and single flowers are obtained; however, the full double flowers are esteemed the most beautiful, and are often the florists' pride.

But all flowers of the above luxuriant nature are commonly called double flowers; observe, however, a Full Flower is to be considered as the highest degree of luxuriance or plenitude, as the petals are generally multiplied in many series to the very centre, so as frequently to choak up all the male and female organs, as sometimes happens in carnations, ranunculus, anemones, &c. a double flower, properly so called, may be said to have its series of petals only twice repeated; however, among gardeners and florists all multiplied flowers, whether their petals are repeated but twice, thrice, or many times, are commonly all denominated double flowers, and are generally in the greatest estimation, as being the most delightful to the eye, in the opinion of florists.

But although full and double flowers are often the most beautiful to the eye, as just observed, yet they are to be considered as an unnatural increase and monstrous production; by Linnæus called vegetable monsters, because double flowers are only varieties of singles, varying by culture from their natural single or *characteristic* state; for the *characters* of the genera are always drawn from single flowers, never from full or double ones, whose number of petals often vary more or less by culture, and are never to be depended on to establish the *characters*.

Full or double flowers therefore are varieties both of monopetalous and polypetalous flowers; for example, the hyacinth, tuberose, primrose, &c. being all monopetalous or of one petal only in their natural or *characteristic* state, yet the increase or repetition of the petals one within another is often continued to the very centre, choaking up the organs of fructification; as aforesaid, though perfect fullness is less frequent in flowers with one petal than in those with several. Polypetalous flowers therefore, such as carnation, anemone, ranunculus, marsh-marigold, columbine, poppy, pæony, tulip, crown-imperial, &c. all having several petals, are liable to all degrees of luxuriance, from the lowest to the greatest fullness.

The mode of luxuriance is effected either by a multiplication of the division of the limb or upper part of the petal, or of the petals entirely; and in flowers having nectariums, the

impletion is often formed by a multiplication of the nectarium, as frequently occurs in columbine, narcissus, larkspur, &c.

Compound flowers are also liable to various degrees of luxuriance; as in African marigold, sun-flower, garden-daisy, feverfew, &c. for an account of the mode of impletion, see *COMPOSITOS flos*.

PLUMBAGO, Lead Wort.

This genus consists of some flowery perennials, of which, one is herbaceous, for the open borders, and the others are ligneous, or undershrubby plants, for the stove; have fibrous roots, sending up slender stalks, three or four feet high, adorned with oval spear-shaped leaves, and terminated by clusters and spikes of small monopetalous flowers.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, is monophyllous, tubular, pentagonal, quinque-dentate, and permanent. COROLLA is monopetalous, funnel-shaped, divided above into five oval-spreading segments; and a nectarium of five very small valves, including the germen. STAMINA, five subulated filaments sitting on the nectarium, and small versatile anthers. PISTILLUM, a very small oval germen, simple style, having a slender five-pointed stigma. PERICARPIMUM, none, a single oval seed lodged in the permanent calix.

There are about four species, the principal of which are the three following.

Hardy Herbaceous Kind.

¹PLUMBAGO *Europæa*.

European Plumbago.] Hath thick, fibrey, descending roots, sending up many slender, channelled stems, branching a yard high; spear-shaped, rough, amplexicaule leaves, and all the stalks and branches terminated by bunches of blue flowers, in October.

Varieties.] With purple flowers — with white flowers.

They are all perennial in root, and annual in stalk; natives of Italy, &c. but succeed in the open ground.

Ligneous Stove Kinds.

These are somewhat undershrubby, and natives of India.

²PLUMBAGO *Zelanica*.

Ceylon Plumbago.] Hath a thick juicy, acrid root, ligneous, very slender, branchy stalks, rising three or four feet high; oval, smooth, leaves, having short foot-stalks; and the branches

branches terminated by spikes of white flowers, appearing great part of the year.

³PLUMBAGO *Rosea*.

Rose Plumbago.] Hath slender ligneous stems, with gibbous or swelling joints; oval smooth leaves, having foot stalks; and all the branches terminated by spikes of red flowers, great part of the year.

All these plants merit culture, to encrease the variety of the flowery tribe; the first sort for the pleasure ground; and the other two to plant in pots, and place in the hot-house collection.

Their propagation is;

The first sort, by parting the roots in autumn, when the stalks decay.

And the second and third sorts by seed, in a hot-bed, in the spring: they may also be tried by slips and cuttings, assisted by artificial heat.

PLUMERIA, Red Jessamine.

The plants are woody, succulent, flowery exotics, of South America; retained here in our hot-house collections, for variety, rising several feet high; ornamented with oval, oblong, and spear-shaped leaves, and beautiful monopetalous funnel-shaped five-parted flowers, terminating the branches in clusters.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, is small, obtuse, and five-parted. COROLLA, is monopetalous, infundibuliform, with a long tube, widening upwards, and the top divided into five oblong, oval, erect, spreading segments. STAMINA, five awl-shaped filaments, having connivent antheræ. PISTILLUM, an oblong, bifid, germen, scarce any style, but a double acute stigma. PERICARPIUM, two long, ventricose, acuminate, nutant, unilocular, and univalvular folliculi; having numerous oblong, imbricated seeds.

The species are;

¹PLUMERIA *Rubra*.

Red Plumeria.] Rises with a woody, thick, succulent, branching stem, eighteen or twenty feet high; large oval-oblong leaves, having short, biglandular-foot-stalks; and the branches terminated by clusters of elegant, red, odoriferous flowers.

Variety.] With pale-red flowers.

²PLUMERIA *Alba*.

White Plumeria.] Rises with a woody, thick, succulent, branchy stem, eight or ten feet high; spear-shaped, pointed, revolute leaves; and the branches terminated by clus-

ters of white odoriferous flowers, with the pedunculi having tuberosc swellings above.

³PLUMERIA *Obtusa*.

Obtuse Plumeria.] Hath a woody, thick, succulent, branchy stem, rising ten or twelve feet high; spear-shaped, short, obtuse leaves; and the branches terminated by clusters of fragrant white flowers.

All these plants flower here in our stoves, in summer, about July and August, but never produce seeds in England.

They being all exotics of the hot parts of America, require the indulgence of a hot-house all the year in this country; and are retained here in many curious gardens, as plants of variety and ornament, for the beauty of their stems, leaves, and flowers, particularly the latter, which rising in large clusters, make a fine appearance, six weeks or two months in summer, and have great fragrance; but those of the *Red Plumeria* are considerably the most beautiful.

All the three species are of a very succulent quality, both in stem, branches, and leaves; replete with a milky juice of a very caustic and poisonous nature.

As being all of the above succulent temperature, and exotics from the hot parts of the world, they must be potted in light, dry, sandy earth, and placed almost constantly in the stove; and supplied with proper waterings, which, however, as being succulents, must be applied with great moderation, particularly in winter, and they must be shifted occasionally into larger pots.

They are propagated by seeds and cuttings of their branches.

By seed.—This is procured from the West Indies; sow it in pots of light sandy compost, and plunge them in a hot-bed under glasses, or in the bark-bed in the stove; they will readily grow; and when the plants are two or three inches high, prick them in separate small pots; which plunge also in the bark-bed, &c.

By cuttings.—Any time in summer, take off some cuttings of the branches, which previous to planting, as being very succulent, should be laid in the stove two or three weeks, or more, as it shall seem necessary, till the wound made by the amputation from the parent plant is perfectly healed and dried over, to prevent their rotting; then plant them in pots of light dry earth, and plunge them in the bark-bed, giving occasional shade from the mid-day sun; and very moderate

shade from the mid-day sun; and very moderate waterings; and they will be rooted in a month or six weeks.

POINCIANA, Barbadoes Flower-Fence, or Spanish Carnation.

It consists of shrubby flowering exotics of the Indies, proper for our hot-house collections; of upright branchy growth, garnished with decompound pinnated leaves; and the branches terminated by long spikes of beautiful pentapetalous flowers.

Class and order, *Decandria Monogynia*.

Characters.] **CALIX**, is five oblong, concave, deciduous leaves. **COROLLA**, is pentapetalous, four of the petals roundish, and nearly equal, and the fifth is larger, deformed and crenated. **STAMINA**, ten very long, bristly, declinated filaments, having oblong antheræ. **PISTILLUM**, a long, awl-shaped, declinated germen, long style, and obtuse stigma. **PERICARPIUM**, an oblong compressed pod, having tranverse partitions, containing many plane nearly oval seeds.

The chief species are,

¹**POINCIANA Pulcherrima**.

Fair Poinciana, or Double Spined Barbadoes Flower-Fence.] Hath a shrubby, upright, straight stem, branching ten or twelve feet high, armed with double spines, at each joint; large, decompound, pinnated leaves, of numerous, oblong, obtuse folioles; and the branches terminated by long loose spikes, of large golden, yellow, beautifully variegated flowers.

²**POINCIANA Bijuga**.

Bijugated Single-spined Poinciana.] Rises with a shrubby, upright, straight stem, dividing into spreading branches, armed with short single spines; decompound pinnated leaves, of numerous, roundish, emarginated lobes; and the branches terminated by loose spikes, of yellowish purple flowers.

³**POINCIANA Elata**.

Spineless Poinciana.] Hath a shrubby, spineless stem and branches; bipinnated leaves, of many small oblong, oval, entire lobes; and loose spikes of flowers, having leathery cups, and very long, dark purple filaments.

These beautiful shrubs flower here in our stoves, in autumn, or beginning of winter, very ornamentally, imparting an agreeable fragrance; but are not succeeded by ripe seed in England.

As they are exotics of both Indies, they must be always kept in pots, and placed constantly in the hot house.

Their propagation is by seed, which we receive annually from the West Indies. Sow it in pots of light earth, and plunge them in any hot-bed, or in the stove bark-bed; they will soon come up abundantly, which when about three or four inches high, prick them into separate small pots, plunging them also in the bark-bed, and, giving occasional waterings, and they will make great progress. As they advance in growth, shift them with balls into larger pots; and grant them supplies of water, plentifully in summer, but always very moderate in winter. Thus they will grow freely, advance fast in height, and in a few years begin to exhibit their elegant flowers.

POLEMONIUM, Greek Valerian, or Jacob's Ladder.

The plants are herbaceous, fibrous-rooted, flowery perennials, for the pleasure-ground; sending up annual stalks from about ten or twelve, to eighteen inches high, adorned with pinnated leaves, and terminated by bunches of monopetalous, rotated, five-parted flowers.

Class and order, *Pentandria Monogynia*.

Characters.] **CALIX**, is monopetalous, five-parted, and permanent. **COROLLA**, is monopetalous, and wheel-shaped, divided at top into five parts. **STAMINA**, five short inclined filaments, having roundish antheræ. **PISTILLUM**, an oval acute germen, filiform style, and a trifid revolute stigma. **PERICARPIUM**, a three-cornered, trivalved, trilocular capsule, having many irregular seeds.

The most noted species are,

¹**POLEMONIUM Cæruleum**.

Blue Greek Valerian, or common Jacob's Ladder.] Hath fibrous roots, crowned by a cluster of pinnated many-lobed leaves, and upright, channelled, hollow stalks, about half a yard high; garnished with pinnated leaves, of several pair of alternate lobes, terminated by an odd one; and the stalks terminated by clusters of blue flowers, having the calix larger than the corolla.

Varieties.] White-flowered—variegated-flowered—woolly-cupped.

²**POLEMONIUM Reptans**.

Creeping Greek Valerian.] Hath very creeping roots, upright branchy stalks, about a foot high, pinnated leaves, of several pair of narrow alternate lobes; and the stalks terminated by bunches of light blue flowers, nodding or drooping downwards.

Both the species flower in May and June;

the flowers are always collected into bunches; each flower is of one petal, divided above into five roundish segments; and are succeeded by plenty of seed in autumn.

These plants are hardy: the first grows wild in thickets, in some parts of England, and other parts of Europe; and the second in Virginia; and both the sorts are cultivated in gardens for ornament, in the flower-compartments of the pleasure-garden; are abiding by the roots, and send up stalks annually in spring, for flowering.

Their propagation is by seed, and by parting the roots; but the seedlings are generally the finest plants: parting the roots, however, is the only certain method to continue the variegated kind, and any other singular variety.

By Seed.—Sow it in spring, in any bed or border of common earth, and rake it in; the plants will soon come up abundantly, which, when two or three inches high, prick out a quantity in nursery-rows, six inches asunder, to remain till autumn; then may be transplanted, where they are finally to remain; and they will flower the following summer.

By parting the Roots.—Autumn, when the stalks decay, or early in spring, before new ones begin to shoot, is the proper time; and is performed in the common way.

POLYANTHES, Tuberose, or Indian tuberous Hyacinths.

It is an herbaceous, bulbo-tuberous-rooted, beautiful flowery perennial, an exotic of India, rising with annual stalks, three or four feet high, terminated by a long spike of many large monopetalous, six-parted, liliaceous flowers, of great beauty, and delightful fragrance.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, none. COROLLA, is monopetalous, infundibuleforme, with an oblong incurved tube, divided above into six oval spreading segments. STAMINA, six thick obtuse filaments, terminated by very long linear antheræ. PISTILLUM, a roundish germen, slender style, crowned by a thick trifid stigma. PERICARPIUM, a roundish, obtusely trigonal capsule, with three cells, having numerous, plane, semi-orbicular seeds, in a double range.

There is but one species, consisting of some varieties, all of which being exotics of tender quality, requiring aid of artificial heat, under shelter of frames and glasses, &c. to bring them to flower in perfection in this country.

The species is,

POLYANTHES *Tuberosa*.

Polyanthes or Tuberosa.] Hath an oblong, bulb-like, tuberous, white root; crowned with a few long very narrow leaves; amidst them an upright, straight, firm stem, three or four feet high, terminated by a long spike of large white flowers, arranged alternately.

Varieties.] Common tuberosa, with single flowers,—double flowered,—dwarf stalked,—variegated leaved.

They all flower here in June, July, and August: the flowers are funnel or bell-shaped; garnish the upper part of the stem, in a long spike, consisting of from ten to twenty or more separate flowers, in alternate arrangement; the lower flowers opening first, which are succeeded by those above, in regular order, making in the whole a most beautiful appearance, highly enriched with a most fragrant odour.

The common single-flowered Tuberose, is the sort the most commonly cultivated, as it generally blows the most freely, and possesses the finest fragrance.

The double flowered kind, also highly merits culture, as when it blows fair, it makes a singularly fine appearance.

The dwarf, and the variegated kind, are inferior to the other two, but may be cultivated for variety.

All the varieties being exotics from warm countries, although they are made to flower in great perfection in our gardens, by assistance of hot-beds, they will not prosper in the open ground, and do not encrease freely in England; so that a supply of the roots is imported hither annually from Genoa, and other parts of Italy, by most of the eminent nursery and seedsmen, and the Italian warehouse-keepers; generally arriving in February or March, time enough for the ensuing summer's bloom; and are sold commonly at the rate of twelve or fifteen shillings per hundred, being careful always to procure as large roots as possible, for on this depends the success of having a complete blow.

They requiring artificial heat to blow them in this country; are planted in pots, and plunged in a hot-bed, under a deep frame, furnished with glass lights; or placed in a hot-house, where they may be blowed to great perfection, with little trouble.

The principal season for planting them is March and April; observing, however, that in

in order to continue a long succession of the bloom, it is proper to make two or three different plantings, at about a month interval; one in March, another in April, and a third the beginning of May; whereby the blow may be continued from June until September; observing, as above mentioned, they may be flowered either by aid of a common dung, or bark hot-bed, or in a hot-house; and the following is the methods.

First by common Hot-beds.—In March or April, &c. as above observed, make a moderately substantial hot bed of dung or tan, in dimensions suitable to any of the deepest hot-bed frames; and when the bed is become of a proper temperature of heat, prepare to put in the roots, previously planting them in pots, as directed below; observing, that if a dung hot-bed, lay in six inches depth of earth, or old tan, in which to plunge the pots, but if of bark or tan, no earth is necessary, as the pots may be plunged immediately into the bark.

The hot-bed being ready, and having procured the roots, and a due quantity of pots twenty fours one for each root; then having light rich earth, fill the pots therewith; and, after having divested the roots of all loose outer skins, and all off-sets, plant one in each pot, in depth, so as the top of the root be about an inch below the surface of the earth: this done, directly plunge all the pots in the hot-bed close together, so as the bed may contain the number required; and as soon as they are all thus placed, put on the lights of the frame.

Being thus planted and placed in the hot-bed, observe their culture as follow: admit a portion of fresh air daily, by tilting the upper ends of the lights; but keep them close down on nights: give also moderate waterings, which however apply very sparingly, till the roots begin to shoot; then repeat the waterings freely every two or three days, or as you shall see occasion; likewise observing, that when the shoot begins to advance, to admit fresh air more freely, in proportion to strengthen the stems, according as they advance in height: and when they have risen near the glasses, it is proper to deepen the frame, either by the addition of another at top, or by raising it at bottom six or eight inches, in order to give the stems sufficient room to shoot to their full stature, repeating this, once or twice, as the growth of the plants renders it necessary, still also indulging them with plenty of water, and a large portion of

fresh air daily, either by tilting the lights as above-said, or that when the plants are advanced some tolerable height, and the warm season also a little advanced, the lights may be taken away entirely occasionally in fine mild days, which will strengthen and inure them gradually to the full air: but always draw the lights on again towards the evening, or at the approach of a sharp air, cold blast, or heavy rains; observing, towards the middle or latter end of May, or beginning of June, according to the temperature of the season, to begin to expose them fully, only giving occasional shelter in cold nights, or very wet weather, either of the glasses, or mats supported on hoop arches, till they begin to flower, which will be about the middle or latter end of June, or beginning of July; when the plants in their pots may be removed where wanted; either to adorn any of the garden compartments, or any apartment of the habitation.

Place to each plant a tall straight stake; to which fasten the stem for support.

They must still be duly supplied with water all the time of their bloom; they will require it every other day, or oftner, in very hot dry weather.

Observe, as aforesaid, that, in order to continue a long succession of bloom of this flower, two more parcels of roots should be planted; one in April, about a month after the first, and another parcel in May; each planting to be in pots, as already directed; and plunged in a hot-bed under shelter of frames and glasses, or an awning of mats every night and cold weather: those however planted late in April or in May, will need only a moderate hot bed, just to set the roots agoing at first, and will succeed tolerably, with only a protection of hoop arches across the bed, for the support of mats occasionally in cold nights.

Sometimes roots planted in May in the full ground, will shoot tolerably strong, and produce flowers in autumn.

It is however the most eligible way to allow them the assistance of a hot-bed as above, otherwise of a hot-house, as directed below; for one or other of these aids is the only method by which we can blow these flowers in full perfection.

By assistance of a Hot-house.] Where there is the convenience of a hot-house, we may blow tuberoses in great perfection with very little trouble. Plant the roots any time in spring,

spring, in pots as above advised; and if there is room in the bark-bed, plunge them to their rims; if not, place the pots any where towards the front of the house; but they will shoot more freely if plunged in the bark-bed; give occasional waterings as directed in the hot-bed culture, and they will shoot and flower strong in their due season; and by a repetition of planting a few at three or four weeks interval, you may continue a bloom from April or May, until autumn.

Method of Propagation.

With respect to the propagation of these plants, it is principally by off-sets of the roots.

The blowing roots that are brought annually from abroad, for sale, are often furnished with off-sets, which ought to be separated, previous to planting; those also that are planted here in our gardens, frequently furnish off-sets, fit for separation in autumn when the leaves decay; they must then be preserved in sand all winter in a dry sheltered place; and in the beginning of March, plant them either in a bed of light dry earth in the full ground, or to forward them as much as possible, allow them a moderate hot-bed, and in either method indulge them with shelter in cold weather, either of a frame and lights, or arched with hoops and occasionally matted; but let them enjoy the full air in all mild weather, giving also plenty of water in dry weather, during the season of their growth in spring and summer.

Thus let them grow till their leaves decay in autumn; then take them up, clean them from earth, and lay them in a box of dry sand to preserve them till spring, at which time, such roots as are large enough to blow may be planted and managed as already directed, and the smaller roots plant again in a nursery-bed, to have another year's growth; afterwards plant them for flowering.

POLYGONUM, knot-grass.

This genus consists of herbaceous perennials and annuals, for adorning the pleasure-garden, and for medical and other uses; rising from about six inches to ten feet high, in different sorts, garnished with oval and spear-shaped leaves, and terminated by branchy spikes of small but numerous apetalous flowers.

Class and order, *Oëlandria, Trigynia.*

Characters.] CALIX, is divided into five oval segments, coloured within, and permanent. COROLLA, none, there being no pe-

tales. STAMINA, eight, very short filaments, crowned with roundish antheræ. PISTILLUM, a triquetrous germen, three very short styles and simple stigmas. PERICARPIUM, none, each floret having a single triquetrous seed wrapped in the permanent calix.

The principal species for our purpose are two perennials, and two annuals.

Perennial Kinds.

These are cultivated in many gardens for variety, but their chief merit is for medical use.

¹POLYGONUM, *Bisflorta.*

Bisflort or Greater Snakeweed.] Hath a thick oblique intorted root, blackish without, and red within; a simple round slender stem near two feet high, oval leaves, having decurrent foot-stalks, and the stalk terminated by thick short spikes, of whitish-red flowers.

²POLYGONUM, *Viviparum.*

Vivaparus Polygonum, or smaller Bisflort.] Hath a thickish root, a simple slender stem, half a foot high, spear-shaped leaves, and the stalk and branches terminated by long spikes of whitish-red flowers.

Both these perennials flower in May and June, succeeded by ripe seeds in August.

They grow wild in England, &c. the first in moist places, the other in mountainous situations; are in great estimation for medical purposes; the root being the part used.

Annual Kinds.

The first of these is a noble ornamental plant, commonly called *Persicaria*; the other is an esculent.

³POLYGONUM *Orientele.*

Oriental Polygonum, commonly called Persicaria.] Hath fibrey roots, an upright, robust, strong, jointed stem, rising eight or ten feet high, dividing at top into several branches; very large oval-lanceolate alternate leaves, on broad foot-stalks half surrounding the stem; and all the branches terminated by long, slender, hanging spikes of reddish-purple heptandrous and digynious flowers, from July till October.

This is a noble annual for the decoration of the large compartments of the pleasure-garden.

⁴POLYGONUM *Fagopyrum.*

Fagopyrum, Buck-wheat, or Brank.] Rises with an upright smooth branchy stem, from about a foot and a half to a yard high, heart-shaped-sagittated leaves, and the branches terminated by clusters of whitish flowers, succeeded.

ceeded by large angular seeds; excellent for feeding pigeons, and most sorts of poultry.

All these plants are hardy, and succeed in almost any soil and situation; the two first are perennial in root, and the third and fourth are annual, wholly decay at the end of summer, or early in winter.

As to their merit in gardening, the following are the particulars:

The first two sorts are retained in some curious gardens, for variety; but their chief merit is for medical purposes: they are powerful astringents, and are used both internally and externally; esteemed very efficacious in hæmorrhages, and other fluxes; and good to heal sore mouths.

Third sort *Oriental Polygonum*, or *Perficaria*, is a most elegant annual for the embellishment of the pleasure-ground; it assuming a majestic tree-like growth by its erect luxuriant stem, and branchy head; which being garnished with noble large foliage, and numerous pendulous spikes of flowers, in constant succession three or four months, exhibits a very ornamental appearance from June or July, until October, and is so easy of culture, that from its scattered seeds in autumn young plants rise spontaneously in abundance the ensuing spring, and shoot up so rapidly, as to attain six or eight feet stature by July, when they generally begin flowering, and continue till attacked by the frost, then totally perish; so that a fresh supply must be raised from seed annually.

The fourth sort (*Buck-Wheat*) is a sort of corn, and is frequently cultivated both by way of fodder, cutting its stalks while young and green to feed cattle; and for its grain to feed pigeons, poultry, hogs, &c. it flourishes in any soil and situation, but generally thrives best in light dry earth; and the driest seasons seldom retards its growth.

Method of propagating all the Sorts.

The first and second sort are easily propagated in plenty, by parting the roots in autumn.

The third sort, *Oriental Polygonum*, being annual, is always propagated from seed annually; either in the full ground, or by aid of hot-beds.

By sowing in the full ground—Some seed may be sowed both in autumn, as soon as ripe, and in spring, about the borders, in patches; the autumn-sowed plants, although they rather rise sparingly, yet those that suc-

ceed, generally rise earlier and stronger in the spring following, than the spring-sowed plants; it is however proper to sow in both seasons; some of which may be in a warm border for transplanting; and others about the borders in patches, finally to remain, covering the seed half an inch deep; they will come up about April or May, if a fine season; which, when three or four inches high, those designed for transplantation should be planted out singly, about the different compartments; and of those sowed in patches, thin out the weakest in moist weather, leaving only one of the strongest plants in each patch; and those thinned out, may also be planted singly where they may be required. According as the plants in general advance some considerable height, place a stout stake to each for support, which is all the culture they require; and they will flower in due season, and furnish plenty of seed.

From the scattered or self-sown seed in autumn, many young plants often rise in spring, and flourish without any trouble.

By hot-beds.—As sometimes in bad seasons, or in cold wet soils, the sowings in the full ground either rise but sparingly, or not till late in spring, probably May or June; it is therefore proper also to sow some in a hot-bed in March, with other annuals, such as African and French marigolds, China asters, &c. for transplantation, which will forward them considerably; but they must be planted out in May or June before they draw up; or if previously pricked upon another hot-bed, six or eight inches asunder, and arched over with hoops, and sheltered with mats in cold nights; and here to have three or four weeks growth, it would bring them more considerably forward, and they may readily be moved with large balls of earth about their roots, for their final transplantation.

The fourth species, *Buck-Wheat*, is also propagated by seed annually, in any open ground, which sow in April or May, either broad-cast and raked, or harrowed in, or in shallow drills, ten or twelve inches asunder, the plants will soon come up, and be fit to mow for cattle in eight or ten weeks, or if to stand, will produce a crop of grain in three or four months.

POPULUS, Poplar-tree; comprehending the Abele, and Aspen-tree, &c.

This genus is composed of hardy deciduous trees, valuable for ornamental and forest-tree plantations; they rising to a considerable height

height and magnitude, garnished with large roundish angulated and heart-shaped simple leaves, and dioecious apetalous flowers, collected into long amentums.

Class and order, *Dioecia, Oelandria*.

Characters.] CALIX, male and female flowers on separate trees, collected into oblong, loose, imbricated amentums, composed of oblong scales, each scale forming a cup to a single floret. COROLLA, no petals, but a monophyllous nectarium. STAMINA, eight filaments, having large four-cornered antheræ. PISTILLUM, an oval acuminate germen, very short style and quadrid stigma.—PERICARPIUM, an oval bilocular capsule, and numerous oval pappous seeds.

There are five species, all of the tree kind, deciduous, and of hardy temperature; will thrive in almost any soil and situation, but are the most prosperous in moist grounds, particularly the first three sorts, which thrive exceedingly in marshy or boggy land, or any watery situation.

The species are.

¹POPULUS *Alba*.

White Poplar, commonly called Abele-tree.] Rises with an upright straight trunk, and regular branchy head, to a great height, having a whitish smooth bark, roundish leaves, indented into several angles, of a dark-green above, and are downy and white underneath.

Comprises these Varieties.] Large-leaved White Poplar — small-leaved — variegated-leaved.

²POPULUS *Nigra*.

Black Poplar.] Rises with a straight trunk, and full branchy head, to a considerable height; having deltoide, heart-shaped, acuminate, serrated, light green leaves.

³POPULUS *Tremula*.

Trembling Poplar, or Aspen-tree.] Rises with an upright large trunk, and a full branchy head, many feet high, having a grey bark, roundish leaves indented into angles, smooth on both sides, with a constant tremulous motion.

The leaves of this species having long slender foot-stalks, are rendered so very tremulous, that they have a constant wavering or trembling motion; hence the name *Populus Tremula*.

⁴POPULUS *Balsamifera*.

Balsamiferous Carolina Poplar.] Rises with an upright large trunk, and a large regular branchy head, to a great height, having a whitish smooth bark, and the young shoots

cornered; large, almost heart-shaped, indented, light shining-green leaves.

This is a very elegant species of *Populus*, of very free growth, and the leaves remarkably large and ornamental.

⁵POPULUS *Heterophylla*.

Heterophyllous Virginia Poplar.] Rises to a great height, having large heart-shaped leaves, hairy at their first appearance.

The two following sorts are also supposed of this genus.

Tatamahacca Poplar, commonly called Tacamahacca or Balsam-tree.] Is of moderate growth, branching out into a full regular head, having middling-sized leaves, some oval, others heart and spear-shaped, whitish underneath, and of a very balsamic odoriferous nature; good to cure green wounds.

Lombardy Poplar.] Rises with a very straight stem, branching erectly, forming a fine regular head, and grows to some considerable height; having large, roundish, acuminate, smooth, light-green leaves—is a remarkable fast shooter, and highly merits culture.

In all these trees the leaves are universally of the simple kind, moderately large, and form a distinguishable diversity in plantations in summer; they expand in spring and decay in autumn, like the rest of the deciduous tribes.

All the sorts flower annually in the spring, but the flowers being only small katkins, make no ornamental show; they are all of the class *Dioecia, i. e.* male and female on separate trees, collected into oblong imbricated amentums or katkins, two or three inches long, the flowers being small florets without petals, situated under the scales of the amentum, appear commonly in March or April; the males come out first, and the females in a week after, and in about five or six weeks are succeeded by ripe seed, which is frequently disseminated by the winds all around to a considerable distance, and often productive of many young plants.

These trees are all of remarkably quick growth, often making shoots whilst young, from three or four to eight or ten feet long in one summer, especially in moist soils, in which they principally delight, and make the greatest progress.

As to their uses in gardening, the following are the particulars.

They may be employed occasionally for ornament in out-grounds, not near fine lawns and

and walks, on account of the great litter the falling of their katkins occasion; but are excellent for planting towards the boundaries of parks, paddocks, and fields, the sides of rivers and brooks, and to intersperse with other trees in large plantations. The White Poplar, or Abele, in particular, also the Carolina, Tacamahacca, and Lombardy Poplar, are very ornamental trees, and are finely adapted to be employed in assemblage in forming large avenues, open groves, and clumps in parks, &c. all the sorts may be employed to advantage in any large tracks of plantation.

If required to ornament any marshy or boggy grounds with plantation, no trees are better adapted for that use than Poplars, especially the first three species, all of which thrive remarkably in moist or boggy ground, and will readily grow by cuttings, either of young shoots or in truncheons.—See their *Propagation*.

As forest or timber-trees, the following three sorts, White, Black, and Tremulous Poplar are proper to be employed for that purpose, especially in any moist boggy ground, where few other trees will thrive: they however will succeed in any other common soil poor or rich, but in a boggy or very moist ground they will be so expeditious in growth as in six or seven years they will afford a considerable advantage, especially if planted close to allow of thinning, for a fall of poles, spars, and for fire-wood, &c. besides leaving a sufficient number of standards at proper distances to grow up to timber, and the stools of the first fall remaining, shoot up again and afford a fall every four or five years, still leaving the timber standards.

Any boggy or marshy land may be improved to much advantage by coppices of these trees, to cut every four, five, or six years for poles, and other small purposes; being planted in rows a yard asunder, and in seven years they will be fit to cut for many small uses, and the stools shooting up again strong, will afford a cutting every four or five years after. See PLANTATIONS.

For all the above purposes young trees are propagated and raised, as directed below in their propagation.

Method of Propagation.

All the sorts of *Populus* are easily propagated by cuttings, layers, and suckers.

By Cuttings.—October and November

is a good season for this work, or even any time in winter until March, in open weather. This is the most expeditious mode of propagating all these trees, for cuttings thereof grow freely without any trouble; either cuttings of the young year-old shoots, a foot and half long, planted a foot deep, or large truncheons of two, three, or more years growth, from about a yard to five or six feet long, planted in moist places: though these large cuttings or truncheons are not proper for any general plantation, only just in some particular parts, in a boggy or watery situation, where shade and shelter may be required as soon as possible, in which may be planted a quantity finally to remain, planting them two or three feet deep.

But, in order to raise plants for any regular plantation, or for a quantity of handsome standards, it is the most eligible to raise them principally from young cuttings of one year's growth, or two at most; procure therefore a quantity of these young cuttings, about fifteen or eighteen inches long, and plant them in nursery-rows a yard asunder, placing each cutting two parts of three in the ground, and about a foot distance in the lines, they will readily take root, and make good shoots the following summer, being careful to trim off straggling laterals, in order to encourage the leading shoot to grow straight, and aspire more expeditiously in height; and after having from two to four or five years growth here, they may be transplanted finally for the purposes above mentioned.

By Layers.—In autumn chuse any lower young shoots conveniently situated, lay them by slit-laying, they will be well rooted and fit to transplant by autumn following, in nursery-rows to have two or three years growth.

By Suckers.—Some of the sorts send up abundance of suckers from the roots, which may be taken up after the fall of the leaf, and planted in nursery-rows, as directed for the cuttings; they will form good plants in two years.

The plants raised by all the above methods, will, after having obtained from two or three to five or six years growth, be of proper size for furnishing any of the aforementioned plantations.

PORTULACA, Purslane.

Two species are found in our gardens; one a low herbaceous succulent annual, a salad herb; the other a low shrubby perennial for the

the green-house, or stove collection, both rising only six or eight inches high, garnished with small succulent leaves, and small pentapetalous flowers.

Class and order, *Dodecandria Monogynia*.

Characters.] CALIX is small, bifid, and placed on the germen, and permanent.—COROLLA, five plane, obtuse, erect petals.—STAMINA, from twelve to nineteen short capillary filaments, having simple antheræ.—PISTILLUM, a roundish germen, short simple style, and five oblong stigmas.—PERICARPIUM, an oval covered capsule, of one cell, having many small seeds.

There are several species, but the two following are the most noted.

PORTULACA Oleracea (Annual.)

Common culinary Purslane.] Rises with herbaceous, low, succulent, branchy stalks, six or eight inches high, garnished with wedge-shaped, thick, succulent leaves, and small close-setting flowers.

Comprises two Varieties.] Green Purslane, having deep-green leaves.—Golden Purslane, having yellow leaves; both the varieties rising from the same seed.

These herbs are excellent to mix in summer fallads.

PORTULACA, Anacampseros (Perennial.)

Anacampseros, or Shrubby Cape Purslane] Rises with a shrubby branchy stalk, about six inches high, oval, gibbous, succulent leaves, and the stalks terminated by small clusters of red flowers.

Both these plants are of a succulent nature; the first is an herbaceous annual, for culinary uses; and the second a shrubby perennial, cultivated by the curious for variety; are both exotics of a tender quality, of the temperature of green-house and stove plants.

The common Culinary Purslane is raised annually from seed for summer use, both as a salad and pot-herb, is of a moist cold nature, and an excellent ingredient to mix in summer fallads, but not proper for winter use; the plant being tender must be raised either in a hot-bed, or in a warm border, in which it will not succeed before April or May.

The shrubby sort must be kept in pots of dry soil, and placed in the hot-house collection.

Method of Propagation.

The propagation of the *Common Purslane* is by seed annually in spring and summer, for, in order to continue a succession of young plants for use, it is proper to sow several dif-

ferent times from March or April until June, July, or August, at about three weeks interval, observing, if required, to have it early: the first sowing may be performed in a slender hot-bed in February or March, and the other sowings may be in a warm border of lightish earth in April and May; though, as the warm season advances, the sowings may be in any open bed or border of light ground. The seed may either be sowed in shallow drills, and covered about a quarter of an inch deep, or all over the surface, covering it that depth, or may be lightly raked in: give occasional waterings in dry weather, both before and after the plants come up, which are to remain where sowed, and they will be fit to cut for use in three or four weeks. In gathering them for use, cut off their young tops with a knife, they will shoot out again after each cutting.

To save seed of this sort leave some strong plants of the April sowing, they will flower and ripen seeds freely towards autumn.

The second sort is propagated by cuttings, any time from April till June or July; plant them in pots of light dry earth, and if plunged in the bark-bed they will root the sooner, giving occasional shade till rooted, and moderate watering.

POTENTILLA, Cinquefoil.

The genus consists of one noted shrubby species, and near thirty herbaceous kinds; the former is a hardy deciduous flowering shrub for the pleasure-ground; and the others having but little merit as garden plants, only a few of them are sometimes admitted in the herbaceous collection for variety. All the sorts are of moderate growth, some growing erect, others trailing, and garnished with pinnated and other compound leaves, and pentapetalous flowers.

Class and Order, *Icosandria Polygynia*.

Characters.] CALIX is menophyllous, half cut into ten parts, alternately smaller, and reflexed.—COROLLA, five, roundish, spreading petals, inserted into the calix.—STAMINA, twenty awl-shaped short filaments, having elongated-lanulated antheræ.—PISTILLUM, numerous small germina collected into a head, many slender styles, having obtuse stigmas.—PERICARPIUM, none, a head of seeds placed on the common receptacle, which lodges in the calix.

There are about six or seven species found in our gardens, one of which is shrubby, the others herbaceous.

Shrubby

*Shrubby kind.*¹POTENTILLA *Fruticosa*.

Shrubby Potentilla, commonly called Shrub Cinquefoil.] Rises with a short shrubby stem, dividing into a branchy full head, three or four feet high; closely garnished with pinnated leaves, of five, oblong, narrow, acute-pointed folioles, pale green above, and whitish underneath; and the branches terminated by clusters of large, spreading, yellow flowers.

This is a beautiful deciduous flowering shrub, worthy a place in every curious collection.—It grows wild in Yorkshire and other northern parts of England, &c. but has been long a resident of gardens as an ornamental shrub.

Herbaceous perennial kinds.

There are about five or six of these kinds common to our gardens; the first of which grows wild in England, and is rarely cultivated; the others are of foreign growth in different parts of Europe.

²POTENTILLA *Reptans*.

Creeping common five-leaved Potentilla, or five-leaved grass.] Hath a thick fibrey root, slender, trailing, repent stalks, digitated, five-lobed, petiolated leaves, and yellow flowers, singly.

³POTENTILLA *Rupescris*.

Mountain upright Cinquefoil.] Hath upright stalks, eight or nine inches high; pinnated, five and three-lobed, alternate leaves, having oval crenated lobes, and the stalks terminated by small white flowers.

⁴POTENTILLA *Recta*.

Erect, seven-lobed, Yellow Cinquefoil.] Hath erect stalks, seven-lobed leaves; having the lobes spear-shaped and serrated; green and hairy on both sides, and the stalks terminated by corymbose clusters of yellow flowers.

⁵POTENTILLA *Fragaroides*.

Strawberry-like trailing Potentilla.] Hath a somewhat tuberous root, furnished with many long fibres, long trailing shoots, rooting at the joints; pinnated, mostly three-lobed leaves, having oval lobes, with the extreme lobe the largest, and clusters of small white flowers.

This species bears a great resemblance to the small sterile strawberry plants.

⁶POTENTILLA *Argentea*.

Silvery upright Potentilla.] Hath upright stalks, branching a foot high; and five lobed leaves, having the lobes wedge-shaped, cut on the edges, hoary and white underneath, and the branches terminated by small yellow flowers.

All these *Potentillas* flower in June and July; the flowers are composed each of five roundish petals, and about twenty stamina.

They are all very hardy plants, and may be employed in the different compartments of the pleasure-ground. The first species in particular, *Shrubby Potentilla*, merits a place in every shrubbery towards the front of the clumps, &c. and the herbaceous kinds may be dispersed about the common compartments to increase the variety.

Their propagation is very easy.

The *Shrubby Potentilla* may be propagated abundantly by suckers, layers, and cuttings; all of which will readily grow, and make plants in one year, which after having two or three years growth in the nursery, will be fit for any of the shrubbery compartments.

All the herbaceous kinds may be propagated by parting the roots in autumn or spring, or by seed in any of those seasons.

POTERIUM, Garden Burnet.

It consists of two herbaceous and one shrubby perennial. Of the former, one is a kitchen-garden herb, the other for the pleasure-garden, and the shrubby kind for the green-house collection; they all rising with upright stalks from about a foot and a half to a yard high, in different sorts; having pinnated leaves, and the branches terminated by spikes of quadripartite monoecious flowers.

Class and order, *Monoecia Polyandria*.

Characters.] CALIX, male and female flowers in the same spike, each floret having cups formed of three oval leaves. COROLLA, in the males is quadripartite, the segments oval, concave, and permanent, and in the females is monopetalous, and wheel-shaped with a short tube, divided above into four oval, plane, persistent segments. STAMINA, numerous capillary filaments, and didymous antheræ. PISTILLUM, two oval-oblong germens, two hair-like, coloured styles, and pencil-shaped, coloured stigmas. PERICARPIMUM, a berry inclosed in the indurated corolla, having two seeds.

Herbaceous kinds.

The first of these herbaceous kinds is an esculent herb, the other for variety in the pleasure garden.

¹POTERIUM *Sanguisorba*, (Perennial.)

Sanguisorba, or common garden Burnet.] Hath fibrey perennial roots, crowned by a large tuft of pinnated leaves, of six or seven pair of sawed lobes, terminated by an odd

one; upright angular stalks, dividing, and branching a foot and a half high, terminated by oblong spikes of purplish red flowers.

This species grows wild in England, in chalky soils, but has been long cultivated as a choice salad-herb for winter and spring use, it being of a warm nature; the young leaves are the useful parts.

It is perennial in root, and retains its radical leaves all the year, but the stalks are annual.

²POTERIUM *Hybridum*.

Hybrid Agrimony-leaved Montpellier Burnet.] Rises with upright taper, closely gathered stalks two feet high; pinnated odoriferous leaves of three or four pair of sawed lobes, terminated by an odd one; and the stalks terminated by long foot-stalks dividing into smaller, each supporting a small roundish spike of flowers.

This species often proves biennial, but by cutting down some of the stalks before they flower, it will cause it to multiply at bottom, and become abiding.

Shrubby kind for the Green-house.

³POTERIUM *Spinosum*.

Shrubby Spinous Burnet of Crete.] Hath a shrubby stem and branches, rising a yard high, armed with spines; small pinnated evergreen leaves, of six or seven pair of lobes, terminated by an odd one, and the branches terminated by small heads of greenish flowers.

All these three species flower in June and July, succeeded by ripe seeds in autumn.

They are all naturally perennial, but the two herbaceous kinds being abiding in root only; the other in root, stem, and branches; and the two former are hardy, and the third requires shelter in winter.

The first sort merits culture in every kitchen-garden for winter and spring salads.

Some plants, both of the first and second sorts, may be introduced in the herbaceous collection in the pleasure-garden for variety.

Keep the third sort always in pots to have shelter in winter.

They are all easily propagated as follows.

The first sort by seed, and by parting the roots.—Sow the seed in autumn or spring, in a border of light earth, and rake it in, and when the plants are two or three inches high, plant them out in any bed or border a foot asunder, finally to remain.—Parting or slipping the roots is performed also in the

autumn or spring season, planting the slips as directed for the seedlings.

The second sort may also be increased by seed and slips off the root, as for the former sort.

And the propagation of the third is by slips or cuttings of the branches in spring and summer, planted in pots, and placed under glasses, giving shade and water; or might be forwarded more by plunging them in a hot-bed.

POTS. Garden Pots for plants and flowers.

In gardening, Pots are particularly necessary in the culture of all tender exotics of the of the green house and stoves, all of which must be planted in Pots for the convenience of moving them in and out of these departments as occasion requires.

Pots are also exceedingly useful in raising many young seedlings and cuttings, that may require moving to occasional shade, shelter, and artificial heat, likewise for many young plants that are tender whilst young, requiring to be removed under shelter for the first two or three winters, but become hardy enough afterwards to bear the full air the year round; and Pots are likewise very convenient in which to plant many of the more curious hardy flowering plants and others, and choice flowering shrubs, &c. to remove occasionally to adorn any particular compartments.

There are about eight different sizes of Garden Pots, which are necessary in order to suit the different sorts of plants, as well as all sorts of plants in their different stages of growth; as when the plants are young and of small size, they may be first planted in small Pots, and as they by degrees increase in bulk, shift them into pots a size larger, repeating it as often as necessary. See *PLANTING in POTS and Shifting Plants*.

The several sizes of Pots are in regular gradation, and at the Pot-houses each size has its name for the convenience of readily supplying the sizes wanted for particular uses; they being always reckoned by the cast, from two to sixty Pots to each, according to their sizes, the largest Pots being only two to a cast, and the smallest sixty; so that as there being eight different sizes or casts: they are distinguished by the following terms, twos, eights, twelves, sixteens, twenty-fours, thirty-twos, forty-eights, and sixties; so according to the above numbers there are so many Pots to each cast; the several casts from the twos, being

being in a gradual diminution, and the price of the different casts are the same; those of two, &c. being as much as those of sixty, and so of the rest; from two to three shillings is the general price per cast at the potter's in the neighbourhood of London.

The principal places in the vicinity of London for the red pot houses, or potters that make Garden Pots, are mostly in the villages contiguous to the river Thames, for the convenience of water-carriage, such as Lambeth, Rotherhith, Deptford, Greenwich, Hammersmith, Brentford, Bow, &c.

In chusing the Pots, see that they are burned sufficiently hard, and so perfectly sound as to ring when struck with your knuckle, and that they have all holes at the bottom to discharge the superfluous moisture from the earth about the roots of the plants; the larger pots having generally four holes, one in the middle of the bottom, and three around the circumference thereof, at equal distances; but the smaller Pots have commonly only one hole in the middle of the bottom.

With respect to the proper sizes of Pots requisite for the different sorts of plants, it is commonly mentioned in their respective genera, when any particular sizes are necessary.

When we occasionally speak of small Pots, it is generally to be understood either as sixties, forty eights, or thirty-twos, according to the sorts or sizes of the plants.

For the method of planting in Pots, &c. shifting plants from one Pot to another, &c. See *Planting in Pots*, under the article PLANTING.

And when any plants are become too large for Pots, they are to be shifted into tubs, as is often necessary for orange and lemon trees, great American aloes and some other large-growing exotics. See TUBS.

PRIMULA. Primrose. Including Polyanthus and Auricula.

This famous genus *Primula* furnishes a grand collection of low, herbaceous, fibrous-rooted, flowery perennials; two celebrated species in particular, *common Primrose* and *Auricula*, have singular merit, as very beautiful spring flowers, and for each species furnishing thousands of varieties, are all of humble growth, with the roots crowned by a cluster of oblong broad leaves, and low slender flower-stalks, from about three or four to six or eight inches high, terminated by monopetalous, five-parted flowers, some singly, others in clusters.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, a many-leaved involucre, containing many small flowers, each having a monophyllous, tubulous, pentagonous cup, divided into five acute erect segments, and is permanent. COROLLA, is monopetalous, with a long cylindric tube the length of the calix, having the limb or upper part spreading, and divided into five roundish heart-shaped segments. STAMINA, five very short filaments, situated in the neck of the corolla, having acute erect antheræ. PISTILLUM, a round germen, slender style, and globular stigma. PERICARPIUM, an oblong, cylindric, unilocular capsule, ten-parted at top, containing numerous small seeds.

There are six or seven species of this genus, two of which demand universal esteem as flowery plants; namely, *Common Spring Primrose*, and *Auricula*; the former of which includes all the family of the Primroses, Cowslips, and all the numerous varieties of Polyanthus; and the latter, all the vast train of the Auricula tribe. The *Auricula*, however, was formerly ranged as a distinct genus; but its general characters determining it a species of *Primula*, modern botanists arrange it accordingly.

PRIMULA Veris.

Spring Primrose.—Consisting of the three following principal varieties, — *Common Primrose*, — *Cowslip Primrose*, — *Polyanthus Primrose*; each having many varieties.

Common Primrose kinds.

Common Spring Primrose.] Hath thick very fibrey roots, crowned by a cluster of large, oblong, indented, rough leaves, and numerous flower-stalks, from about three or four to five or six inches high, each terminated commonly by only one flower, of different colours and properties in the varieties.

Varieties of these are.] *Common yellow-flowered Primrose* of the woods—*White Primrose*—*Paper-white Primrose*—*Red Primrose*—*Double yellow Primrose*—*Double white Primrose*—*double red Primrose*.—All of which varieties having generally but one flower on each stem, but rise in such plenty from every part as to appear almost covered with flowers.

They all flower abundantly in March and beginning of April, continuing a month or six weeks.

All these varieties of *Common Spring Primrose*, are hardy perennials: the single yellow sort grows wild in woods, &c. in most parts of England; all the others being seminal or seedling varieties of it, that have been principally obtained by culture in gardens. The double kinds in particular have singular beauty; the flowers being large, and perfectly full and double, and make a fine shew, highly meriting culture in the best collections of spring-flowers.

These varieties in general delight mostly in shady situations, whereby all the sorts, both single and double, are proper ornaments for the borders of shrubberies, wilderness quarters, and shady walks, where they will flower abundantly, and make a fine appearance. Some plants may also be dispersed in other more open compartments for variety.

Prodigious quantities of the single *Primrose* plants are brought to London, every spring, by the herb-women, which they gather in the neighbouring woods, when in full bloom, taking them with roots, and sell them about the streets.

The propagation of all these varieties is effected abundantly by slipping or parting the roots. Numerous single kinds may also be raised from seed, sowed in a shady border in autumn or spring, as directed for the *Polyanthus*; but raising seedlings is hardly worth practising, since they encrease so plentifully by the roots.

Remarking, however, that the propagation by slipping or divided the roots is the only method for encreasing the double kinds; and as these sorts are the most beautiful, and multiply in tolerable plenty by off-sets, it is proper to raise a good stock of them, which may be effected with great facility every year soon after their flowering is past, as they will then be increased into bunches; therefore being furnished with some good roots, proceed to their propagation in autumn, about July, August, or September; taking them up out of the ground, and divide each bunch of plants into several slips, and directly plant them in a shady border of good rich earth, six or eight inches asunder, and each slip will become a good plant, and will flower strong the following spring.

Observe, it is proper to remove and part the roots of the double kinds, in particular, every year; but not to omit once in two years at most, in order to preserve the plants in vigour.

Cowslip kinds.

Cowslip-Primrose, or Cowslip.] Hath very thick fibrey roots, crowned by a cluster of oblong, indented, round leaves, and upright firm flower-stalks, five or six inches high, terminated each by a cluster of small yellow flowers, and other different colours and properties in the varieties.

Varieties of these are.] Common single yellow *Cowslip* of the meadows and pastures—Double yellow *Cowslip*—Scarlet *Cowslip*—Hose-and-hose *Cowslip*, one flower growing out of the bosom of another, the lowermost serving as the calix; all of which varieties having the flower-stalks crowned by many flowers, in bunches.

They flower in April and May, continuing in succession a month or six weeks.

All the varieties are hardy perennials, some of them inhabitants of meadows and pasture grounds, particularly the common single yellow sort, in great abundance; which sort is of excellent use in medicine, and a fine cordial wine is made of the flowers. Some plants of all the varieties merit admittance in the pleasure garden, to increase the variety of the spring bloom, but principally the double kinds, placing them in the fronts of some shady moist borders, &c. they do not, however, succeed so well immediately under shade of trees, &c. as the common *Primroses*.

The propagation of these sorts is principally by parting the roots, as directed above for the common *Primrose*: this method of propagation is, however, particularly necessary for all the double kinds, and having a few roots of each sort, they will multiply exceedingly by off-sets, and soon encrease your stock.

Polyanthus kinds.

Polyanthos Primrose, commonly called Polyanthus.] Hath thick fibrated roots, increasing into large bunches, crowned with a cluster of large oblong indented rough leaves; amidst them upright flower-stalks six or eight inches high, terminated mostly by a cluster of several spreading flowers, of many different colours and variegations in the varieties.

Varieties.] The varieties of *Polyanthus* are innumerable in the different colours and variegations of the flowers; but the principal colours are—Purple-flowered—Red-flowered—Gold-coloured—Orange-coloured, &c. each having numerous intermediate shades and variegations, that sometimes in one bed or border

border of seedlings we may discover many hundred different sorts, and the varieties may still be increased without end from seed; and the select varieties of each sowing may all be continued and increased plentifully by slipping the roots, which annually multiply into large bunches, and may be parted or slipped with the utmost facility into many separate plants.

They all flower beautifully in April and May, and often flower again in autumn, and sometimes in winter, in very mild seasons; but the spring is their principal season of flowering in the greatest perfection, and ripen seeds abundantly in June or July.

This variety, *Polyanthus Primrose*, is one of the most beautiful of our fibrous-rooted spring flowers for the open borders, remarkable for its wonderful seminal diversity, all of which are hardy perennials, that flourish in almost any common soil and situation, but delight most in a loamy or other rich moist soil, and in a somewhat shady border; in a shady situation, however, they continue considerably longer in full bloom than in a sunny exposure; for a fierce sun often greatly affects these flowers both in beauty and duration; it is therefore proper to plant a collection of the finest sorts in the shade, not immediately under trees, &c. but in some eastward shady border, sheltered by a wall, hedge, or other fence from the noon-day sun, planting them at six or eight inches distance; and here the plants will continue flowering in full beauty a month or six weeks, but a quantity of different varieties should also be dispersed in the fronts of the several borders contiguous to the principal walks, in assemblage with other flowers, in which they will effect a very agreeable variety.

The *Polyanthus* is one of the noted prize-flowers among florists; many of whom are remarkably industrious in raising a considerable variety of different sorts, as well as use every art to blow them with every requisite perfection; for among those virtuosi, a *Polyanthus* must possess several particular properties to have admittance in their choice collections.

But there are numerous varieties of *Polyanthus*, that, although destitute of some of the properties required by florists, are nevertheless very pretty flowers for ornamenting the common borders.

The chief properties however of a florist's *Polyanthus* are principally the following:—

1. The stem or flower-stalk shall be upright, moderately tall, with strength in proportion, and crowned by a good regular bunch of flowers, on short pedicles, strong enough to support them nearly in an upright position.
2. The florets of each bunch should be equally large, spread open flat, with the colours exquisite, and the stripes and variegations lively and regular.
3. The eye in the centre of each floret should be large, regular, and bright; and the antheræ, by the florists called the thrum, should rise high enough to cover the mouth of the tube or hollow part in the middle of the florets, and render them what they call thrum-eyed; but when the style elevates the stigma above the antheræ, the eye of the tube generally appears hollow, shewing the stigma in the middle, like the head of a pin, is hence called pin-eyed, and is rejected as an incomplete flower, although its other properties be ever so perfect.

But although the florists reject a pin-eyed *Polyanthus*, it is the flower in its most perfect state; and great numbers of them are of as beautiful forms, colours, and stripes as the thrum-eyed varieties, and demand equal attention as furniture for decorating the common flower compartments, &c. or to exhibit a general shew in a bed or border.

The method of propagation for the *Polyanthus* is, by seed, and by parting the roots.

By Seed.—This is the only method of propagation to gain new varieties, and to raise a large stock of plants, as a blow of many new flowers may be annually obtained for the choice collection, and a large supply for the common borders: the season for sowing the seed is, either in autumn, soon after it is ripe, or early in spring; in either season of sowing they will soon come up, but will not flower till the second spring; observing, however, that by sowing early in autumn, the plants generally come up freely the same year, be fit to plant out betimes the next spring, and become stronger plants by the spring following, capable of flowering in greater perfection than the spring-sowed seedlings: remarking if you sow in autumn let it be in July or beginning of August, and if in the spring, perform it in February, March, or beginning of April: and the sowing in both seasons may be performed either in large pots or boxes of rich earth, in order to move to different situations occasionally, or in an east border of light rich soil; but sowing in pots or boxes may,

may be the most eligible for the autumn sowing, for the convenience of moving to a little shelter in frosty weather; in either method sow the seed on the surface moderately thick, covering it evenly with light earth only about a straw's breadth thick, or if sowed in a border, it may either be raked in very light and evenly, or covered as above; the plants will appear in three or four weeks, observing that if sowed in boxes, &c. they should be removed to a shady border during the warm weather, and those of the autumn sowing to a warm situation in winter, allowing them also some protection from frost.

In the spring, or beginning of summer, when the plants of either sowing are one or two inches high, they should be planted out in somewhat shady borders, as formerly mentioned, about five or six inches asunder, to remain for flowering; which they will all effect the following spring, when those of good properties should be marked, and the others may be transplanted into the common flower-borders.

Observe, that although all the select varieties may be multiplied plentifully by dividing the roots as directed below; yet it is necessary to raise a quantity of seedlings every two or three years, both to obtain new varieties, and to keep up a stock of young plants to succeed the old ones, which after the third year's bloom rarely flower so strong and fair as the one or two years old seedlings.

It is proper likewise to continue increasing the more excellent sorts, by parting the roots.

By Parting the Roots.—By this method all the sorts may be propagated in great abundance every year, for the roots multiply exceedingly by off-sets into large bunches, so as to admit of slipping or parting annually in autumn; and every slip furnished with some fibres will readily grow, become a good plant, and flower the following spring; so that in the propagation by parting the roots any particular approved sorts may be multiplied every year at pleasure.

The proper time of year for this work is, any time in summer and beginning of autumn, after the plants have done flowering; but if performed in July or August, the slips will have good time to get strength before winter, so as to flower strong next spring.

At the proper time therefore take up the plants out of the ground, and divide each

bunch into several slips, not too small, unless where as great an increase as possible is wanted, being careful to preserve some root to each slip, they are then to be planted in a fresh dug border, enriched with dung, setting them five or six inches asunder, give water directly, and repeat it occasionally till they have taken good root.

When a large quantity of these plants are required for sale, or for the supply of markets, either the roots to plant, or the flowers for nosegays, a quantity should be raised every year, both from seed and by slips as before observed, and planted out early in autumn, in beds or borders six inches asunder; and after having one year's growth, they will be of a proper size for sale.

Great quantities of the common sorts are brought annually to Covent-garden and Newgate Market every spring when in bloom for sale, when they sell for about a shilling per dozen of roots; though the fine sorts are rarely brought to market, and they fetch a much greater price.

Auricula Kinds.

²PRIMULA *Auricula*.

Auricula Ursi, or *Bear's-ear*; but commonly called *Auricula*.] Hath a thick fibrated root, crowned by a cluster of oblong, broad, fleshy, serrated, smooth leaves, resembling the shape of a bear's ear, and amidst them upright flower-stalks from about three or four to six or eight inches high, terminated by an umbellate cluster of beautiful flowers, of many different colours and variegations in the varieties.

It is a native of the Alps, but has been a long resident of our gardens.

Varieties of this.] The varieties of this are amazingly numerous both in the diversity of the leaves and flowers, such as oblong-leaved—roundish-leaved—broad-leaved—narrow leaved—green-leaved—white or mealy-leaved, being covered with a fine mealy dust or farina. And of flowers there are, purple-flowered, numerous sorts of lighter or darker shades, stripes and variegations—red-flowered, numerous varieties of lighter or darker reds, striped and variegated sorts—yellow-flowered, several varieties, as bright yellows, buff-coloured, dun-coloured—double purple-flowered, double yellow-flowered, variegated purples, and innumerable other most beautiful varieties. All the varieties, both self coloured and variegated sorts, have a circular eye in the middle of each flower, and

and of which there are, yellow-eyed—white-eyed—and the petals of most of the sorts are powdered with a most delicate farina, or mealy powder, which contributes exceedingly to the beauty of the flowers.

Of the above principal varieties there are innumerable diversities, and many new ones annually acquired, which being all first obtained from seeds, though as the seedlings vary so greatly, it is probable that not one in a hundred may prove a real good flower; but when once any excellent new varieties are gained, they may be increased annually by off-sets, to a large stock, and continued for ages; and the fine sorts, according as they are obtained, are all named by the florists, sometimes by that of the person who first raised them, but more frequently that of some illustrious personage, which they number and book accordingly.

They all flower in April and May, continuing a month or six weeks in beauty, and ripen plenty of seeds in June.

All the varieties are hardy, herbaceous, ever-green perennials, that prosper in any common soil of a garden not too wet in winter; for being somewhat succulent, a very humid soil in that season is apt to rot them: allowing them however any moderately dry soil, they will stand all weathers the year round.

Considered as flowery plants, they claim precedence of most other spring flowers, for their admirable beauty and wonderful variety; and among florists are esteemed the most beautiful of their prize and stage flowers, the fine sorts being planted in pots, in order for placing them upon elevated covered stages or stands, during their bloom, both to shew the flowers to greater advantage, and to defend them from the full sun and showers of rain, which would impair their beauty, and hasten their decay: a share of the common sorts should also be disposed in the open borders in assemblage, or you may likewise plant a collection together in some bed or border to shew a general bloom; for they will prosper in any open ground, not under shade and drip of trees, &c. and are rarely injured by the most inclement weather.

But a quantity of the principal varieties with requisite properties should always be kept in pots, in order for moving to different situations for the advantage of blowing the flowers in the greatest perfection.

The principal properties necessary to con-

stitute a good Auricula are, the flower-stem should be upright, tall, and strong enough to support its cluster of flowers tolerably upright; the cluster or truss of flowers should be large and regular, somewhat of a roundish form, all the florets of the bunch being sustained on short pedicles, in order to support the whole in a proper position, to form the truss close and regular; the florets should be large and the top spreading flat and regularly around, and the eye of each floret large, circular, and bright.

Flowers having nearly the above properties, being of fine colours, particularly the most beautiful variegated kinds, are proper sorts to plant in pots (twenty-fours or thirty-twos) for stage flowers; so that when you raise seedlings, &c. you should previously see them blow, to discover their properties before you pot them, which may be done early in autumn, when the flowering is past, planting one plant in each pot, and place them in the shade all summer, and in a warm situation in winter, and in spring, according as the flowers open, place them on some covered stage as before observed.

But in the culture of the fine varieties of Auriculas, the florists generally prepare a particular compost earth; the principal one is, light earth from some pasture ground, the top spit with the sward, or any other good light mould, and neats dung or good rotten hot-bed dung, having of the earth and dung an equal portion of each, and about half the quantity of drift or sea sand; and sometimes where rotten wood becomes earthy, such as willow earth, old rotten tan, saw-dust, &c. can be obtained, a portion is also added, mixing and forming the whole into an heap, to remain about a year, turning it over several times, and it will be of a proper temperature for use. — See COMPOSTS.

In default however of the above mixtures, you may take any good light earth of a garden, blended with an equal portion of perfectly rotten dung, and a little drift sand if possible.

Their Propagation and general Culture.

The method of propagating all these plants is by seed, to gain new varieties, and by slipping the roots to multiply the approved kinds.

By Seed.—By raising seedling plants we are sure to gain some new varieties, and being raised one year, they begin to flower the next, though

though it is probable, that out of hundreds, there may be but very few real fine flowers; but when once any new excellent sorts are so obtained, they multiply annually by off-sets to increase the stock.

The seed generally ripens in June, and should be sowed in July or August, not later however than September; or it may be done in spring; but by sowing early in autumn you gain time.

For this purpose get some large pots or boxes filled with light rich compost, sow the seed on the surface, and cover it scarcely a straw's breadth deep, and directly place the pots or boxes where they may have only the morning sun during the hot weather, giving them moderate waterings, and if sowed early in autumn, the seedlings will probably rise in tolerable plenty the same year; in October, however, remove the pots, &c. to a warm sunny situation for the winter, or may be placed in a garden-frame to have shelter from frost, and excessive wet or snow; but let them enjoy the free air in all moderate weather; early in March replace them again in the shade to have only the morning sun, for the quite young seedlings of these plants are unable to bear the sun fully; therefore continue them in this situation all spring and summer, supplying them with water in dry weather; and in July following take opportunity of moist weather, and prick them out in nursery-beds, or in large pots or boxes, filled with good compost; in either of which prick the seedlings pretty close, *i. e.* two or three inches asunder, giving water and occasional shade from the sun till fresh rooted, or if in pots or boxes, remove them to a shady situation: in these beds or pots, &c. they are to remain till they flower, which will be spring following, when all the good sorts should be marked, or may be directly transplanted into separate small pots (twenty-fours) one plant in each; and next year they will all blow in perfection, and discover their properties more perfectly, then may be shifted into larger pots (thirty-twos); observing to manage them as hereafter directed.

The ordinary sorts will do to plant in the common borders, to form variety amongst other low spring flowers.

By Off-sets, or dividing the Roots.—By this method all the select varieties are propagated, for the roots throw out off-sets in tolerable plenty, each of which being slipped off and planted, will next spring produce flowers ex-

actly like the parent plant, and these in their turn produce off-sets for further propagation, which will produce also the same sort of flowers, &c. and thus may the choice varieties be annually increased, and continued for years.

The season for performing this work is, occasionally both in spring and autumn; if only to slip off any outside off-sets that appear, it may be done in spring, either before or at the time of flowering, though towards autumn, about July or August, when the flowering season is past, and the plants having had the spring and summer's growth to furnish strong off-sets, will be the most eligible season for any general propagation by slips: the roots may be then either taken up and divided into several slips, where a considerable increase is required, or the roots may stand, and only detach any outside off-sets, as aforesaid; and in either season or method of slipping or dividing the plants, proceed to pot the off-sets or slips of the choice sorts separately, but the common kinds may be planted in beds of rich earth.

Having however slipped or divided the off-sets of the fine varieties, then being furnished with a quantity of small pots, twenty-fours or thirty-twos, according to the size of the slips, filling them with the proper compost, plant one off-set in each pot; give some water to settle the earth, and promote their striking; and then place them under some shady fence, upon level clean ground, to have only the morning sun all summer, repeating the waterings in dry weather two or three times a week; and at the approach of winter place them under some warm wall open to the sun, to remain until spring, and begin to shew their flowers, when the choice sorts should be placed on the Auricula stage, in order to protect the bloom from the weather, and preserve them as long as possible in beauty.

General Management.

In the culture of the fine Auriculas in pots, it is proper, as before hinted, to have some sort of covered stage, having the front open to the morning sun only, on which to arrange the pots of plants when in bloom, to shew the flowers to good advantage, and protect them from rain and too much sun: the stage should have several ranges of narrow shelves, one above another, on which to set the pots; some stages are so constructed as to turn round any way at pleasure, more or less to the sun; and some

some are formed circular, having the shelves arranging in a pyramidal manner, and some have canvas curtains to draw or let down occasionally, either to break off driving rains, or afford shade from the sun.

On these stages the pots of plants should be placed in the spring, according as the flowers of each plant begins to open, and not before, to remain during the continuance of the beauty of the flowers; observing to supply them with water about three times a week, or every other morning, giving it only to the earth in the pots, at least let none fall on the flowers, for wet would greatly deface the bloom.

When the full blow is past, remove the pots directly into the full air in a shady border to receive the full benefit of the free air and rains, to encourage their off-sets and the ripening of seeds.

During the summer season they should remain constantly in the shade, but not under drip of trees, and must have proper waterings in dry weather.

In July or August the plants should be fresh potted into new compost, but more especially such plants as have thrown out some good off-sets, should have them separated and potted as already directed; though small plants that have made no progress in off-sets, may remain unremoved another year; observing, however, that July or the beginning of August is the best time for fresh potting them, still continuing them in the shade during the hot weather, and supply them with water.

At the approach of winter remove the pots under some warm situation open to the sun, to remain till spring, or may be placed under some hoop-arches, or in a garden frame, and there occasionally sheltered from severe frost, great rains, and snow, to preserve them in greater vigour, but must constantly enjoy the full air in all mild weather; in default, however, of such shelters, arrange the pots close along under a warm wall, for the plants are very hardy, only observing, that when very wet or snowy weather begins, lay the pots down on one side with the plants towards the sun, to prevent their receiving too much moisture, which would rot these kind of plants; but as the spring advances, place them upright again, that the flower-bud may take its proper upright direction.

In spring, about the beginning or middle of February, it is proper to mould up the

pots with some fresh compost; first take out some of the old mould at a convenient depth without disturbing the roots and clear the plants from any decayed leaves, then immediately fill up the pots with new earth: this will prove a very beneficial dressing both in strengthening the bloom and encouraging the growth of off-sets.

When the plants begin to shew their flower-buds, occasional shelter, if sharp frosts happen, will be of great service in preserving them from being blighted, which often prevents their blooming fair, and sometimes entirely destroys the flower; it is therefore advisable to use a slight covering of mats every frosty or very cold night about the first shooting of the buds.

And according as the flowers open fairly remove the pots on the stage, &c. to remain to blow as already directed.

The further management of the potted plants after flowering is the same as before, and which is to be repeated every year.

³PRIMULA *Farinosa*.

Farinosa *Primula*, commonly called *Bird's-eye*.] Hath a fibrous root, with a small scaly head, crowned by several long, smooth, crenated leaves, mealy underneath, and upright flower stalks half a foot high, terminated by a cluster of small red flowers, having yellow eyes in the center.

It grows naturally in the North, but is cultivated in many gardens as a flowering plant; produces its flowers in the spring.

Plant it in any common border, it will flower annually and multiply plentifully by off-sets.

PRINOS Winterberry.

Two shrubby species compose this genus, one is deciduous the others an ever-green, both hardy shrubs for the shrubbery, &c. obtain eight or ten feet stature, garnished with oblong leaves, and menopetalous wheel-shaped flowers.

Class and order, *Hexandria Monogynia*.

Characters.] *CALIX*, is monophyllous, six parted and permanent. *COROLLA*, is one wheel-shaped petal cut into six oval segments. *STAMINA*, six awl shaped short filaments and oblong obtuse antheræ. *PISTILLUM*, an oval germen terminating in a short style, and obtuse stigma. *PERICARPIUM*, a roundish sex-locular berry, having six hard seeds.

The species are,

¹*Prinos Verticillatus*, (deciduous)

5 E

Virginia,

Virginia deciduous Winterberry.] Grows six or eight feet high, very branchy from bottom to top; large spear-shaped longitudinally-sawed leaves placed alternately, and small flowers from the sides of the branches, some singly, others two or three together, succeeded by purple berries remaining all winter.

²*Pinos Glaber* (ever-green.)

Smooth Ever-green Canada, Winterberry, Yapon, or South Sea Thea Shrub.] Grows eight or ten feet high, branchy quite from the bottom, oblong spear-shaped leaves serrated at the top, placed alternately, and at the axillas small flowers two or three together, succeeded by purplish berries continuing all the winter.

Both these shrubs are of America, are tolerably hardy, especially the deciduous kind, and have been long in our gardens as ornamental shrubs to encrease the collection in the shrubbery, &c.

But the ever-green kind being of a more tender nature, it is also kept in pots in order to be wintered in a green-house.

They are propagated mostly by seed sowed soon after they are ripe or early in spring, in a bed of light earth, covering them full half an inch deep, some of which will probably come up the first spring, but if not sowed till the spring they often remain in the ground till the spring following, unless forwarded in a hot-bed: when the plants are one or two years old they should be planted out in nursery rows; it will also be proper to plant some of the ever-green kind in pots to have occasional shelter the first two or three winters as being rather somewhat tender whilst young; but when they have gathered strength turn some of them out into the full ground, and retain some in pots as green-house plants.

PRUNING.

Pruning is an operation of the knife performed upon trees occasionally, in order both to give them any desired form, and to retrench or reduce irregular and redundant or superfluous growths, or whatever creates confusion and disorder.

But this operation is particularly necessary to be practised on many sorts of fruit-trees, more especially the dwarf sorts, such as all kinds of wall and espalier fruit-trees; it is also necessary to be performed occasionally upon standard trees, both dwarfs and half and full standards, to all of which proper Pruning is necessary; some sorts annually, as all kinds

of wall trees, espaliers, and most other dwarf or trained fruit-trees; which being requisite in order to preserve the proper figure, and to keep them within their limited bounds, as well as to promote fruitfulness; but as to common standards whose heads having full scope of growth every way, they require but very little Pruning, except just to retrench any occasional redundancy, ill-growing branch, and dead wood. Wall trees and espaliers however, require a general regulation of Pruning twice every year, in summer to retrench the evidently superfluous and ill-placed shoots of the year, and to train in a supply of the most regular ones; and in winter to give a general regulation both to the supply of young wood left in summer and to the old branches where necessary.

For in Pruning wall trees and espaliers it is to be observed, that as these trees having their branches arranged with great regularity to the right and left one above another parallelly, about five or six inches asunder, forming a regular spread, so as the branches of each tree completely covers a certain space of walling, &c. and as the whole spread of branches constantly send forth every year a great number of unnecessary and useless shoots; and that as each tree being limited to a certain space, as just observed, an annual pruning is consequently most necessary to retrench the redundancies, and all irregular and bad shoots to give the proper bearing branches due room, as well as to enable us to confine each tree within its allotted limits, consistent with its regular form.

The first Pruning necessary for fruit-trees, is when we attempt to give the head its first regular formation, effected by Pruning short or heading down in spring all the shoots produced the first year from budding and grafting, that is, the first shoots from the budding, &c. when a year old being generally pruned down in March, within four or five eyes of the bottom, whereby it throws all the sap into the remaining lower buds, and thus, instead of running up to one stem, it pushes forth several strong shoots from the lower part the ensuing summer so as to fill the allotted space of walling and espalier regularly quite from the bottom; which shoots being trained strait and regular in a spreading manner, each at full length all summer; and in winter or spring following, if a supply of more principal shoots shall seem necessary to form the head more effectually,

usually, prune short also these shoots each to four or five eyes, and each of them will throw out the like number of shoots the same year, which, according as they advance in length, train at regular distances at full length during the summer as before observed, for the shoots of wall trees should never be shortened in the summer season, for this would cause them to push forth many trifling lateral shoots; though sometimes, in order to fill a vacancy as soon as possible, strong young shoots being pinched early in the season, as in May or beginning of June, to four or five eyes, will throw out several proper shoots the same summer, repeating however the work of Pruning short occasionally one or two years, &c. as above, either in general or to particular shoots as it may seem proper till a proper set of branches are by that means obtained to give the head of the tree a proper formation; afterwards Pruning short is to be omitted except occasionally to any particular shoot to fill a vacant space: but some sorts of wall trees require almost a general shortening of their supply of shoots, such as peach, nectarines, &c. which bear only on the young wood; have that of each year shortened, to force out a supply of shoots for future bearing: other sorts of wall-trees and espaliers are not in the general course of pruning to be shortened, such as pears, apples, plums, and cherries, which bear in the old wood from two or three to many years growth. See DWARF TREES and ESPALIERS.

After the trees are thus furnished with a proper spread of branches trained regularly to the wall and espalier, they will every year throw out many more shoots than are wanted, or can be converted to use, by being some too numerous, others ill placed, and others of a bad growth, all of which must therefore be regulated accordingly by proper pruning, for as the regular figure of the tree, well furnished in every part equally from the bottom to the top of the wall or espalier with proper branches, capable of producing a reasonable quantity of good fruit, are the principal objects of Pruning, all our operations must be directed to these ends.

We must therefore be careful to ease the trees of every thing that is either superfluous, irregular, or hurtful, by Pruning twice every year, a summer and a winter Pruning. We call that superfluous which though good and well placed, yet are more than are wanted or can be properly laid in, and that irregular which is so ill placed as it cannot be trained

with regularity to the wall or espalier, such as all fore-right shoots, being such as grow immediately from the front or back of the branches in a fore-right direction, which though good of themselves, yet their situation renders them irregular or unfit for training; and we call that hurtful which is in itself of bad growth, such as all very rank or singularly luxuriant rude shoots; so that the superfluous or redundant growths should be thinned by Pruning out all that seem to cause confusion, and the irregular and hurtful rank shoots should be displaced, cutting every thing of all these sorts off quite close to the place from whence they proceed, leaving however a proper supply, more or less, of the regular or best placed side-shoots where necessary, so as to preserve every part well furnished with bearing wood, trained straight and close to the wall or espalier at equal distances; observing some sort of wall-trees, &c. require a general annual supply of young wood, such as peach and all other trees which bear only on the shoots of a year old; others require only an occasional supply of wood, such as apples, pears, &c. and all other kinds that bear on the old wood of from two or three to ten or twenty years old or more, so that the same branches continuing in bearing many years, the trees require only a supply of young shoots now and then to replace any worn out and dead branches. See *Summer and Winter Pruning*.

For the mystery of Pruning consists in being well acquainted with the nature of bearing of the different sorts of trees, and forming an early judgment of the future event of shoots and branches, and many other circumstances, for which some principal rules may be given; but there are particular instances which cannot be judged of but upon the spot, and depends chiefly upon practice and observation.

The nature or mode of bearing of the different sorts of wall and espalier trees, &c. is materially to be considered in Pruning.

For example, peaches, nectarines, apricots, &c. all produce their fruit principally upon the young wood of a year old, that is, the shoots produced this year bear the fruit the year following, and the same of every year's shoots, so that consequently, in all these trees, a general supply of the best regular shoots of each year must be every where preserved at regular distances quite from the very bottom to the extremity of the tree on every side in such order as to seem coming up

up regularly one after another, which being trained principally all at full length all summer: but in winter Pruning, a general shortening less or more, according to the strength of the different shoots, is necessary in order to promote their throwing out more effectually a supply of young wood the ensuing summer, in proper places for training in for next year's bearing, the fruit being generally produced all along their sides immediately from the eyes, they rarely forming any considerable fruit-spurs, as in the apple, pear, &c. but the same shoots both produce the fruit and a supply of shoots at the same time for the succeeding year's bearing.

Vines also produce their fruit always upon the young wood, shoots of the same year arising from the eyes of the last year's wood only, and must therefore have a general supply of the best regular shoots of each year, trained in, which in winter Pruning must be shortened to a few eyes in order to force out shoots from their lower parts only, properly situated to lay in for bearing the following year.

Figs bear also only upon the young wood of a year old, and a general supply of it is therefore necessary every year; but these shoots must at no time be shortened, unless the ends are dead, because they always bear principally towards the extreme part of the shoots, which if shortened would take the bearing or fruitful parts away: besides, these trees for the general part naturally throw out a sufficient supply of shoots every year for future bearing without the precaution of shortening.

And as to apple, pear, plum, and cherry trees, they generally bear principally on spurs arising in the wood of from two or three to ten or twenty years old, the same branches and spurs continuing bearing a great number of years, so that having once procured a proper set of branches, in the manner already directed, to form a spreading head, no farther supply of wood is wanted than only some occasional shoots now and then to supply the place of any worn-out or dead branch as before hinted; the abovementioned spurs or fruit-buds are short robust shoots, of from about half an inch to one or two inches long, arising naturally in these trees, first towards the extreme parts of the branches of two or three years old, and as the branch encreases in length the number of fruit-buds encrease likewise accordingly; this therefore determines, that in the general course of

Pruning all these kind of trees, their branches that are trained in for bearing must not be pruned or shortened but trained at full length; for if they were shortened it would divest them of the very parts where fruit-buds would have first appeared, and instead thereof, would throw out a number of strong unnecessary wood-shoots, from all the remaining eyes; therefore let all the shoots or branches of these trees be trained principally at full length, and as they advance still continue them entire, thus they will all readily form the afore mentioned little spurs or fruit-buds from almost every eye; when indeed there is a vacancy, and there is only one shoot, where two or three may be requisite, in which case only pruning or shortening is allowable in these trees, to force out the supply required. See the different sorts under their proper genera, also the article DWARF-TREES.

In these trees great care is necessary to preserve all the proper fruit-buds or spurs, which are readily distinguished by their short, thick, robust growth rarely exceeding one or two inches long.

In the general course of Pruning all sorts of wall and espalier trees, that when displacing the superfluous and ill placed woods, &c. always take them off quite close both in the summer and winter Pruning, not leaving any spurs or stumps of them an inch or two long, as often done, which fills the tree full of disagreeable stumps, and which pushing out strongly from every eye, crowds the tree with a multitude of unnecessary and irregular shoots, and causes great confusion and obscurity, and exhausts the sap to no purpose, as well as occasions a great deal of labour to retrench them; remember therefore, that all shoots and branches necessary to be retrenched must be taken off quite close to the place from whence they arise; which in the summer Pruning if attended to early, while the shoots are quite young and tender, they may readily be rubbed off quite close with the thumb; but when the shoots become older and woody, as they will not readily break, it must be done with a knife, cutting them as close as possible, and all winter Pruning must always be performed with a knife.

It should also generally be observed in Pruning in summer, that all the necessary supply of regular shoots that are left for training in should never be shortened during

ing this season, unless to particular shoots to fill a vacancy for by a general shortening in this season, all the shoots so treated would soon push again vigourously from every eye, and run your trees into a perfect thicket of useless wood; therefore all sorts whether they require shortening in the winter Pruning or not, should, in the summer dressing, be layed in at full length.

Two seasons of pruning are requisite for all sorts of wall and espalier trees, a summer and a winter Pruning.

Summer Pruning.—The summer Pruning is a most necessary operation; every one must know that in spring and summer wall and espalier trees abound with a great number of young shoots that require thinning and other reforms to preserve the beauty of the trees and encourage the fruit, and the sooner it is performed the better; it is therefore advisable to begin this work in May or early in June, and timely disburthen the trees of all evidently redundant or superfluous growth and ill placed and bad shoots, which may be performed with considerably more expedition and exactness than when after the trees have shot a considerable length and run into confusion and disorder by their shoots forming a thicket, when it will in a manner be impossible to see what you are about; besides the disadvantage of choaking up the fruit behind such a thicket of wood and leaves: it is therefore of great importance to perform this operation in the month of May or early in June, or when the same year's shoots are sufficiently formed to enable you to make a proper choice, and tender enough as to require no other instrument than the thumb to displace the bad growths and superfluities.

However, at any rate, let the work of summer Pruning be began before the trees have so far advanced in shooting as to cause much confusion, which would cost you a great deal of pains, precaution, and perplexity, to penetrate and break through the obscurity to determine what is proper to retrench or what to leave.

In this Pruning, we observed above, that a great many more shoots arise from all the principal branches than are wanted, or that can possibly be trained with regularity, or that are well placed or proper for the purpose; our business therefore now is to thin and regulate them, by pruning away the superfluous shoots, and all such as are ill placed

and of bad growth as aforesaid: as to superfluous shoots they are to be considered as such when any tree throws out a redundancy of wood, or much more than what is wanted, or that can be trained in; of these you must now retrench the most irregular placed, weakest, and all such as are evidently not wanted for use, and where two or more shoots any where arise from the same eye, clear all away but one of the best, reserving a sufficiency of the moderately strong and most regular placed side shoots, and always a leading one at the end of every branch, all of which to be trained in to chuse from in the winter Pruning, leaving more or less in proportion, according to what the trees are, or the mode of bearing as before hinted; though in all those trees that bear always on the young wood leave rather more shoots at present than what may appear just necessary, especially of peaches, nectarines, apricots, vines, figs, &c. for it is highly requisite to reserve regular wood enough in the summer to chuse out of in winter Pruning to lay in for next year's bearing; but as to apples, pears, plums, cherries, &c. which continue bearing many years on the same branches, should leave only here and there some good shoots towards the lower parts or in any vacancy till winter, and if then not wanted they are easily retrenched. Ill placed shoots being such as either grow directly from the front or back of the branches straight fore-right, (called fore-right shoots,) or any other ways so ill placed as not to admit of training with regularity, so must all be cut out quite close; and bad or hurtful growth being considered as any very luxuriant shoots, distinguished from the others by their rank, vigorous shooting, and are like to prove injurious by drawing all the nourishment, and impoverishing the neighbouring ones that are of more moderate growth, should generally be removed, except where any may seem proper to leave to fill a vacant space, in which it may be pinched early to three or four eyes, when it will furnish you with the like number of more moderate shoots to fill the vacancy.

Where however a tree is in general inclined to luxuriandy, it is proper to retain as many of the regular shoots as can be commodiously trained in with any regularity, in order to divide and exhaust the too abundant sap which causes the luxuriandy; for by humouring somewhat the natural inclination of luxuriant

luxuriant trees by leaving plenty of branches and these mostly at full length, is the only method by which we can the most readily reduce them to a more moderate state of growth.

Pay particular attention always to the lower parts of your trees, for frequently we shall find proper shoots arising in places necessary to be trained in, either to supply a present or an apparent future vacancy, or as a reserve to replace any decayed or worn out or other bad branch, so that if moderately strong well placed shoots arise in such parts, they are particularly to be regarded at this time; and in winter Pruning such of them as are not wanted may be easily cut out.

All weak trifling shoots should now also be taken out, unless any shall appear useful to fill a vacancy, or likely to be of service hereafter.

Observe in this Pruning not to disturb the natural fruit-buds or spurs, before described.

After having summer Pruned and cleared any tree from all useless shoots as above, let all the remaining proper shoots be directly, or as soon as they are long enough, trained in straight and close to the wall or espaliers and all of them at full length during the summer season, for the reasons before given; not shortening any at this time except as before observed, when there is any great vacancy, when pinching to three or four eyes may be proper; but let all the rest be trained at full length till winter Pruning, when they must undergo another regulation and shorten those of such trees as require it, as peach, nectarine, &c.

The work of training in the shoots in this season is, if against walls, both by nailing by means of proper shred and nails, and occasionally by fastening in the smaller shoots, with little sticks or twigs stuck between the main branches and the wall; and for espaliers tie them with small oziers, rushes, or bafs strings.

Having thus summer dressed and trained your trees, it will be necessary to review them occasionally, in order to reform such branches or shoots as may have started from their places or taken a wrong direction, also that according as any fresh irregular shoots produced since the general dressing may be displaced; and likewise as the already trained shoots advance in length or project from the wall or espalier, they should be trained in close, still continuing them at full length during their summer's growth, for

every thing should be kept close and regular all summer, whereby your trees will appear beautiful to the eye, and the fruit will shew itself and attain its due perfection.

For by thus properly summer Pruning and training wall and espalier trees early in the summer, you preserve their regularity and prosperity, and by clearing out all the unnecessary and useless growths, training the rest close and regular, the fruit will receive all requisite advantage from the sun, air, rains, &c. and it will of course attain the greater perfection both in size, beauty, and flavour.

Winter Pruning.—In the winter Pruning a general regulation must be observed both of the mother branches and the supply of young wood laid in the preceding summer, and the proper time for this work is any time in open weather from the fall of the leaf in November until March.

In performing this work of winter Pruning, it is proper to unnail or loosen great part of the branches, particularly of peaches, nectarines, apricots, vines, and such other trees, as require an annual supply of young wood.

First look over all the principal or mother branches, and examine if any are worn out or not furnished with parts proper for bearing fruit, according to the rules before illustrated with respect to the nature of bearing of the different sorts of trees; and let such branches be cut down to the great branch from which they proceed, or to any lower shoot or good branch they may support toward their bottom part, leaving these to supply its place; likewise examine if any branches are become too long for the allotted space either at sides or top, and let them be reformed accordingly by shortening them down to some lower shoot or branch properly situated to supply the place, being careful that every branch terminates in a young shoot of some sort for a leader, and not stumped off at the extremity, as is too often practised by unskilful pruners.

From the principal or larger branches pass to the shoots of the year, which were trained up in summer, first cutting out close all fore-right and other irregular shoots that may have been omitted in the summer Pruning; likewise all very weak shoots, and those of very luxuriant growth, unless it be necessary to keep some to supply a vacant place; then of the remaining regular shoots, you are to select a greater or smaller portion to leave either as a general supply for next year's bearing as in the case for peach, nectarine,

tarine, apricots, vines, and figs; or only some occasional shoots, as in apples, pear, plum, and cherry trees, to supply the place of any bad or dead branch.

But as peach, nectarines, apricots, vines, and figs, always bear principally on the year-old wood as before noticed, a general supply of young shoots must be left in every part from bottom to top at regular distances, all of which, except the fig, must be more or less shortened according to their situation and strength to encourage their furnishing more readily a proper supply of shoots in spring and summer for next year's bearing, as before observed, leaving the strongest shoots always the longest, as is more fully explained under each of their respective *genera*; but as the figs always bear towards the end of the shoots they must not be shortened.

And with respect to the apples, pears, plums, cherries, &c. as they continue to bear on the old branches of from two or three to many years standing, they only require an occasional supply of young wood, according as the branches become unfit for bearing and want removing, so should accordingly train in here and there in proper places some good regular young shoots towards the lower part, to be coming gradually forward to a bearing state, to be ready to replace worn out and other useless branches; and what shoots are not now wanted for that purpose cut them out close, not leaving any spur or stump, as every one of which, as we before observed, would push out several strong unnecessary shoots the next spring to the prejudice both of the trees and fruit: have particular regard to preserve the shoots at the termination of all the already trained branches entire, not however suffer more than one shoot to terminate each branch; preserve also carefully all the proper fruit-spurs; likewise observe, that the supply of young wood occasionally reserved, and the branches in general of these trees, should all be trained in at full length, and continued so in future, as far as the limited space will admit, and according as any extend above the wall or espalier or any where beyond their proper limits, they should be pruned down with discretion to some convenient bud, or lateral shoot, or lower branch, which train also entire.

In this Pruning, as in the summer dressing, it is of importance to have a strict eye to the lower parts of wall-trees, &c. to see if there is any present vacancy or any that apparently will soon happen, in which cases, if any

good shoot is situated contiguous, it should be trained in either at full length, or shorten it to a few eyes to force out two or more shoots if they shall seem necessary; for precaution should ever be observed in taking care to have betimes a sufficient stock of young wood coming forward to fill up any casual vacancy, and substitute a new set of branches in place of such as are either decayed or stand in need of retrenchment.

Sometimes in wall-trees and espaliers there are many large disagreeable barren spurs, consisting both of old worn-out fruit-spurs, and of clusters of stumps of shortened shoots projecting considerably from the branches, occasioned by unskilful Pruning when retrenching the superabundant and irregular shoots, which instead of being cut out close, are stumped off to an inch or two long, and in the course of a few years, forming numerous barren stumps, as above said, and very little fruit, the trees appear like a stumped hedge; it is therefore, in this season of Pruning, advisable to reform them as well as possible by cutting all the most disagreeable stumps clean out close to the branches, leaving these at full length, especially of apples, pears, &c. as before advised; and reserve an occasional supply of young wood in different parts, and thus in two or three years you may reduce such trees to a regular figure and a proper state of bearing.

Bad Pruning ruins many a good tree, as is observable in numerous gardens, where the wall trees and espaliers appear as just above described, pruned every year, yet never produce any tolerable crop of fruit.

The reason is, the operation or art of Pruning is much more generally practised than understood; different pruners have different ideas of Pruning: many proceed upon little or no principle, and often prune all trees alike, and their idea of Pruning often consists in retrenching annually most of the young shoots, and shorten all the branches of every tree without exception to the great injury of some sorts, and retarding their bearing: likewise many pruners in retrenching the superfluous and irregular shoots, instead of cutting close, as formerly observed, they often stump them off to about one or two inches long; these remaining stumps shoot out again from every eye, and fills the tree with more numerous useless shoots than before, which being also pruned down to stumps of an inch or two long, as above, practising the same every Pruning, so as in the

the course of a few years every branch is loaded with clusters of large rugged barren spurs, formed wholly of the stumps of shortened shoots, occupying the places where fruit-buds might be expected: it is also observable, that many pruners think every branch of all sorts of wall trees whatsoever must in the annual Pruning undergo the discipline of the knife, so shorten all without distinction and reluctance, often too with so much severity on trees that should not be shortened, as to destroy the very parts where fruit-buds would have been produced, they thinking this general shortening necessary to strengthen the branches, which, however, in many sorts, promotes a too vigorous growth, particularly in trees that produce their fruit on natural spurs, forming themselves gradually all along the sides of the branches, first towards the extreme parts, that shortening not only cuts off these first fruitful parts of the branches, but throws the sap back with so much vigour to the remaining buds, that instead of forming fruit spurs almost every bud pushes out luxuriant shoots, and the trees are continually crowded with unnecessary wood, causing a great annual trouble to retrench it, without the pleasure of having a quarter of a crop of fruit: besides the annually cutting out so much strong wood is very prejudicial to some sorts of fruit-trees.

Too severe Pruning is greatly prejudicial to the health of some sorts of stone fruit-trees, in particular, by causing them to gum and soon decay.

Plums and cherries, in particular, are often greatly damaged by a too severe discipline of the knife, these trees being very liable to gum by large amputations, it is therefore of importance to attend to these trees well in the summer Pruning, to retrench all the superfluous and irregular shoots betimes in the summer while quite young, and pinch others occasionally where wood is wanted to fill vacancies, so as to require but little Pruning out of large wood in winter.

But if our former hints in the summer and winter Pruning are attended to in retrenching the useless wood every year at the time advised, you will always preserve your trees free from all incumbrance and every part will be regularly filled with bearing wood, and their general management will prove easy.

A general nailing, &c. must every year be performed according as we advance with the Pruning.

Therefore it is proper that every tree as soon as pruned be directly nailed to the wall, or if espaliers, tie them to the treillage, observing, that in the winter Pruning, as the work of nailing, &c. will require to be performed more or less upon all the branches, we must be careful to train them with great regularity, nailing them along horizontally, as straight and close as possible, never cross any of the branches, but train them distinct and parallel five or six inches asunder, as formerly advised, or in proportion to the size of the leaves and fruit of the different sorts, making the opposite branches of each side arrange equally in the same position.

Thus far is principally all we have to advance respecting the general mode of Pruning wall and espalier trees; particulars for each sort being noticed more fully under their proper *genera*; but what we have here advanced under this article *Pruning* is to convey some general hints to unexperienced pruners, though there are many expedients and resources, not to be discovered but by repeated practice.

Pruning Standards.

Standard fruit-trees require but very little Pruning, for as their branches having full scope to extend themselves every way, they must not be shortened; besides, as our standard fruit-trees, consisting principally of apples, pears, plums, and cherries, which, as before said, bear fruit on natural spurs arising towards the upper parts of the branches, which, as observed in the wall-tree and espalier Pruning, determines that we must not shorten them, nor practise any other Pruning than just to reform any great irregularity, &c.

The first occasional Pruning however, necessary for standard fruit-trees is the first two years of their growth, in order to form their heads somewhat regular, by retrenching any irregular shoots, and when designed to have them form more regular spreading heads, it is customary to prune the first shoots when a year old down to four or five eyes, in order to force out lateral shoots from these lower buds the following summer, to give the head a proper formation. After this suffer the branches to take their natural growth, except

cept that, if while the trees are young, any very luxuriant shoots ramble away considerably from all the others, and draw most of the nourishment, it is proper to prune them, either by retrenching entirely very irregular ones, or shorten others more or less, so as to cause them to branch out consistent with the requisite form of the head.

But let it be remarked in general, that except in such cases of reducing irregularities, let the heads of all kinds of standards always branch away as fast as possible, both in length and laterally, agreeable to their natural mode of growing; and they will naturally furnish themselves abundantly with bearing wood.

Observe however, that as in standard trees of some years growth, irregularities and disorder will occasionally happen, which should be regulated a little by Pruning the most conspicuously irregular and redundant growths; performing it always in winter.

For instance; where any branch grows right across others, or in any other awkward direction, to incommode or cause confusion in the head, it should be retrenched close; likewise any branch that rambles considerably from all the rest, should be reduced to order, by cutting it down to some convenient lower branch, so as to preserve some regularity. Where the head is considerably crowded with wood, let the worst of the redundancy be thinned out as regularly as possible, cutting them close to their origin; observe likewise where any vigorous shoots arise in the heart of the tree towards the bottom of the old branches, and grow upright and crowd the middle of the head, they should be constantly retrenched to their very bottom; cut out also any very cankered parts, and all decayed wood, and clear off all suckers from the root and stem.

Standard trees thus disburthened from any considerable irregularities and confusion, so as all the proper branches have full scope to spread free and easy in their natural manner, they will not fail to repay the trouble in the superior quality of their future fruit.

Pruning Forest Trees, &c.

With respect to Pruning of forest and ornamental trees, flowering shrubs, &c. it is very inconsiderable.

Forest trees, &c. must be suffered to run up as fast as possible, so their heads must not be shortened; all that is necessary is, to prune off lateral branches occasionally from the

stem, or if while young, any lateral shoot of the head is of a very rude rambling growth, and draws all the nourishment, it is proper to reduce it as you see convenient; but otherwise suffer the top and all the branches of the head to remain entire, and take their own natural growth; only prune lower stragglers occasionally; observing, however, it is very improper to trim up the stem too high, as often practised to forest trees, as scarce to leave any head: never, therefore, trim the stem much higher than the full spread of the head, for a full head is both ornamental and essentially necessary to the prosperity of the tree. See *PLANTING*.

And as to the shrub kind, they should also, for the general part, take their own growth at top; and only prune occasionally any lower stragglers, from the lower part of the stem, or any very irregular rambling shoot of the head, and all dead wood: but except in these cases, let their heads mostly shoot in their own way, according to their different modes of growth, in which they will appear always the most agreeable.

Where, however, it is required to keep shrubs low, in any particular compartment, you must regulate this as you shall see convenient, either with a knife or garden-shears, though knife Pruning is the most eligible.

Pruning Implements.

For the purpose of general Pruning, several implements are necessary, such as Pruning-knives, saws, chizzels, hand-bills, hatchets, &c.

As to Pruning-knives, two or three different sizes are requisite, in order to enable us to prune neatly; a strong one for cutting out larger branches, shoots, &c. and a small one for the more exact Pruning among the smaller branches and shoots of peach and nectarine-trees, &c. these knives are generally made curving at the point; they should not be too long, broad, and clumsy, but have rather a shortish narrow blade, and but very moderately hooked at the point, for when too crooked they are apt to hang in the wood, and not cut clean; it is also proper to be furnished with a strong thick-backed knife, to use by way of a chisel occasionally, in cutting out any hard stubborn stumps, &c. placing the edge on the wood, and with your nailing hammer strike the back of it, and it will readily cut through even and smooth.

Pruning hand-saws are proper for cutting out any large branch too thick and stubborn

for the knife; they should be of moderate sizes, one of which should be quite small and narrow, in order to introduce it occasionally between the forks of the branches, to cut to exactness.

As saws generally leave the cut rough, it is proper to smooth it with a knife or a pruning-chissel.

Pruning-chissels are necessary to use occasionally, both to cut off any thick hard branch or stump, and to smooth cuts after a saw; they should be flat, and from about one to two inches broad; sometimes large strong chissels, fixed on a long pole, are used in Pruning or lopping branches from the stems of high standard forest trees, one man holding the chissel against the branch, while another, with a large mallet or beetle, strikes the end of the pole.

A hand-bill and hatchet are also necessary to use occasionally among larger kinds of the standard trees.

All these Pruning tools, in their proper different sizes, may be had at all the cutlery shops and ironmongers, also of many of the nursery and feedsmen; and as the expence of the whole will be but trifling, every one should furnish himself properly.

PRUNUS, Plum-tree; comprising also the Cherry-tree, Apricot, &c.

This noted genus comprehends different sorts of valuable fruit-trees, some flowering shrubs, and beautiful ever-greens; and to some it may seem strange to see the Cherry-tree, Apricot, Laurel, &c. arranged as species of the Plum-tree, as being formerly considered each as a distinct genus; but late discoveries in botany prove them to be all species of *Prunus*, and modern botanists range them accordingly; all the species of which are of hardy growth, garnished with simple, spear-shaped and oval leaves, and pentapetalous icosandrious flowers, succeeded by drupaceous fruit.

Class and order, *Icosandria Monogynia*.

Characters.] CALIX, is monophyllous, bell-shaped, five-parted, and deciduous. COROLLA, five large, roundish, spreading petals. STAMINA, twenty or more filaments inserted into the calix, and short didymous antheræ. PISTILLUM, a roundish germen, slender style, and orbicular stigma. PERICARPIUM, a roundish drupaceous fruit, inclosing a roundish, compressed, hard nut.

The principal species of this genus are—common cultivated Plum-tree, having nu-

merous varieties: Bullace-tree—Sloe-tree, or Black-thorn—Cherry-tree, having many varieties—Padus, or Bird Cherry—Apricot-tree, many varieties—and Laurel-tree:—observing, that although all of the same genus, several of the sorts differ materially from one another, we therefore think it eligible to range or class them according to their nature or kinds, under the following heads—Plum kinds—Cherry kinds—Apricot kinds—Laurel kinds, &c. all however under the generical name *Prunus*.

Plum Kinds.

Under this head we may comprize three species, viz.—1. Cultivated Plum-tree, and its numerous varieties. — 2. Bullace-tree. — 3. Sloe-tree.

PRUNUS domestica.

Domestic Prunus, or common cultivated Plum-tree.] Grows twenty or thirty feet high, garnished with oval spear-shaped leaves, and with the pedunculi for the most part singly, terminated by white flowers, succeeded by Plums, of many different shapes, sizes, colours, and properties in the varieties.

Varieties.] The varieties of the above species are very numerous, especially of the fruit; all the different sorts being varieties of this species, though the trees of the different varieties often differ somewhat in their growth, some being strong shooters, others moderate, and frequently vary in the size and colour of their shoots and leaves; those bearing large fruit have generally larger leaves in proportion; and the shape, size, &c. of the fruit is also very considerable in different varieties, some being round, others oval, and some being not much larger than Cherries, others as large as eggs; and some are yellow, others red, and some green, &c. all of which varieties ripen perfectly in our gardens and orchards.

Principal varieties of the fruit are,

White Primordium, or Jean Hative Plum.—A smallish, oblong, yellow Plum, powdered with a white bloom, esteemed chiefly for its early perfection; ripe the middle or end of July.

Morocco, or early black Damask Plum.—A middle-sized, round, blackish fruit, powdered with blue, is well flavoured, and discharges the stone; ripe end of July.

Little Damask Plum.—A small, round, black, well-flavoured Plum; ripe end of July or beginning of August.

Great

Great Damask Violet Plum.—A moderately large, roundish-oval, dark-blue Plum, covered with a violet bloom, is of a rich juicy flavour, and quits the stone; ripe in August.

Queen Claude Plum, sometimes called Green Gage.—A middle-sized, round, yellowish-green Plum, having a firm deep-green pulp, of a fine rich flavour, and quits the stone; ripe in September.

Little Queen Claude Plum.—A small, round, whitish-yellow Plum, powdered with white, and parts from the stone; ripe end of August and beginning of September.

Green Gage Plum.—A middle-sized, roundish, green Plum, sometimes purplish on the sunny side, having a yellowish-green firm pulp, of a most delicious rich flavour, but does not discharge the stone freely; is one of our most valuable Plums, and the tree a great bearer; ripe the end of August and beginning of September.

Varieties.] There are several varieties of greenish Plums, that go by the name of Green Gages, that are of inferior quality.

Blue Gage Plum.—A middle-size, roundish, blueish Plum, of a rich flavour; ripe beginning or middle of September.

Orleans Plum.—A middle-sized, round, pale-red Plum, often of a whitish-green colour on the side away from the sun; is of but a middling flavour, and quits the stone clean. The tree is of spreading growth, a remarkably great bearer, and very profitable for common use, and for those who supply the markets; ripe end of August and beginning of September.

Drap d'Or, or Cloth of Gold Plum.—A middle-sized, roundish, bright-yellow Plum, spotted with red, of an excellent vinous flavour, and adheres to the stone; ripe beginning or middle of September.

Black Perdrigon Plum.—A middle-sized, oval, dark-coloured Plum, powdered with a violet bloom; is of a fine rich flavour; ripe middle or end of August.

Blue Perdrigon Plum.—A large, roundish, blueish-coloured Plum, replete with a delicious juice; ripe end of August.

White Perdrigon Plum.—A middle-sized, oblong, whitish-yellow fruit, covered with a white bloom; is firm, juicy, rich, and quits the stone; ripe end of August and beginning of September.

Roche Courbon, or Red Diaper Plum.—A middle-size, round, fine-red Plum, powdered with a violet bloom, is high flavoured, and adheres to the stone; ripe end of August.

Red Imperial Plum.—A large, oblong-oval, flattish, pale-red Plum, covered with a whitish bloom; is of but a middling relish, and parts from the stone; ripe middle of September.

White Bonum Magnum, Mogul or Egg Plum.—A remarkably large, oblong, egg-shaped, whitish yellow Plum, powdered with a white bloom, having a firm pulp that cleaves to the stone; more esteemed for culinary use, than eating raw: the tree shoots strong, with very large leaves; is a great bearer, and the fruit is the largest of the Plum kind; ripe beginning or middle of September.

Red Bonum Magnum, sometimes called the Great Imperial Plum.—A very large, oblong, deep-red Plum; not of a rich flavour, but is excellent for preserving and culinary purposes; ripe beginning or middle of September.

Fotheringham Plum.—A large, oblong, fine-red Plum, having a fine rich pulp that quits the stone; ripe end of August and beginning of September.

Brignole Plum.—A largish, oval, yellowish Plum, tinged with red next the sun, having a firm, dry, rich pulp, is in much estimation for sweetmeats; ripe in September.

Le Royal Plum.—A large, roundish, light-red, finely-powdered Plum, having a juicy sugary pulp, that cleaves to the stone; ripe end of August and in September.

Cheston Plum.—A middle-sized, oval, blackish-blue Plum, powdered with a violet bloom; ripe towards the middle of September.

Wentworth Plum.—A large, oval, yellowish Plum, of an acid relish, and separates from the stone; is a good culinary fruit; ripe in September.

Mirabelle Plum.—A small, round, greenish-yellow Plum, having a rich pulp, that discharges the stone, and the tree a great bearer; ripe end of August.

Apricot Plum.—A large, round, yellowish Plum, having a firm, dry, sweet pulp, that separates from the stone; ripe beginning or middle of September.

St. Catharine Plum.—A large, oblong, oval, yellowish-amber-coloured Plum, powdered with a white bloom, having a rich juicy agreeable pulp, adhering close to the stone: ripe end of September.

Imperatrice Plum.—A middle-sized, roundish, dark-red, finely-powdered Plum, of an agreeable flavour, the pulp adhering to the stone; ripe beginning of October.

Little Green Damask Plum.—A small, round, greenish Plum, powdered with a whitish bloom, having a green very agreeable pulp adhering to the stone; ripe middle or end of of September.

Pear Plum.—A moderate-size, oval, whitish-yellow Plum, of an inferior flavour, esteemed principally for preserving; ripe late in September.

Muscel Plum.—A smallish, oblong, flat, dark-red Plum, of but an indifferent relish; ripe in September.

Damascene Plum.—A small, roundish, dark-blue Plum, of a tolerably agreeable acid relish, both for eating and culinary purposes, and the tree a great bearer; ripe in September.

St. Julian Plum.—A small, round, dark-violet-coloured fruit, covered with a mealy powder, has but little relish; ripe end of September.

Cherry Plum.—A very small, round, cherry-shaped red Plum, valued chiefly as a curiosity; and the tree is often planted among flowering shrubs, for the sake of its beautiful bloom in spring, and its cherry-like fruit exhibit a pretty variety in summer; though by its flowering very early, the bloom is often cut off, and seldom succeeded by much fruit.

Thus far is principally all the most noted varieties of this fruit cultivated in the English gardens, and in the nurseries for sale; though there are numerous other varieties, particularly of the common sort, growing in the orchards and hedges of farmers, &c. in different parts of the country; all the sorts being varieties of one species, first obtained from seed, and the approved sorts of them have been multiplied and continued by budding and grafting. See their *Propagation*.

But besides the above varieties of the fruit, there are also the following for ornamental plantations.

Double-blossom Plum-tree—Gold striped-leaved—Silver striped-leaved—and the stoneless Plum.

The two following species, *Bullace-tree* and *Sloe-bush*, grow wild in hedges, but are sometimes cultivated both for variety and use.

²PRUNUS *Infitia*.

Wild Plum, or Bullace-tree.] Grows twelve or fifteen feet high, the branches somewhat spinous; oval leaves, hairy underneath, and the pedunculi by pairs, terminated by white flowers, succeeded by small, round, Plum-like fruit, of different colours in the varieties.

Varieties are] Common black fruited—White-fruited—Red-fruited; all of which ripen late in autumn. They are very acid, though of a tolerably agreeable flavour, and by many esteemed very wholesome, if eaten when quite ripe. They grow wild in the hedges in many parts of England, &c. in great abundance, so are not often cultivated: a few plants however merit culture for variety, particularly in the shrubbery and wilderness compartments, where they will effect an agreeable diversity in autumn when in fruit.

³PRUNUS *Spinosa*.

Thorny Prunus, Black-thorn, or Sloe-tree.] Grows ten or twelve feet high, very branchy and bushy quite from the bottom, armed with strong sharp spines, small, spear-shaped, smooth leaves, pedunculi growing singly, terminated by flowers, succeeded by small, round, black berries, in autumn. It grows wild every where in hedges and woods, and is very proper to plant for field hedges, being of very quick close growth. See *HEDGES*.

The above three species are all that are proper to arrange under this head, considered as of the Plum kind in respect to the growth of the trees, and nature of the fruit; though the first species only, and its varieties, are proper for general culture.

The trees of all the sorts are of the deciduous tribe, of hardy growth, and prosper in any common soil and exposure; they all flower or blossom profusely in the spring, April, and beginning of May, and make a fine appearance; all the flowers of every sort consist each of five small petals, and twenty or more stamina, the flowers and fruit being produced on short spurs arising from the sides and ends of the branches; and the fruit ripens in autumn, gradually in different sorts from the beginning of July until October; exhibiting a most delightful variety in the different colours, shapes, and sizes, of the cultivated Plum kinds in particular, as well as afford a most useful supply for family use, both as excellent table fruit, and for various culinary purposes, and for preserving, &c.

With respect to the merit of the different species, &c. the first sort, *Cultivated Plum-tree* and varieties, every one knows their value as fruit-trees, and no good garden should be without a collection of the best sorts; and as to the ornamental varieties, double blossom kind and striped-leaved sorts, as also the Cherry Plum, they are proper for decorating the shrub-

shrubbery; but the second and third species, *Bullace-tree* and *Sloe-bush*, they are only sometimes admitted in shrubbery compartments, &c. for variety, particularly the former, the fruit of which cause an agreeable diversity whilst growing, and afford variety at table, when all the more richer stone-fruits are gone: as to the *Sloe-tree* however, its principal merit is to plant for forming field hedges, as before observed; it grows thick from the very bottom, and makes a strong close hedge.

The *common Plum-tree* and its varieties may be trained both as dwarfs for walls and espaliers, &c. and standards and half standards; those however trained against walls and espaliers generally produce the largest and fairest fruit, so should always train some of the best sorts in both these ways, and may have any of the varieties as standards in the garden or orchard.

Propagation of all the above Species and Varieties.

First, the common *Plum-tree*.—As to the method of raising *Plum-trees*, all the varieties were first obtained by seed, *i. e.* from the stones of the fruit; and the approved kinds, so acquired, were afterwards multiplied by grafting and budding, for they do not continue the same sorts from seed, as from the seed of one tree there may rise many different sorts, and probably not one like the mother-tree, nor very few that produce a fruit worth eating; but being in possession of any approved sorts, they may be multiplied at pleasure, by ingrafting shoots or buds of them into any kind of *Plum-stocks*.

The general propagation therefore of *Plum-trees* is, by grafting and budding, and may also be increased occasionally by layers; but the two former are the most eligible methods of propagation.

By Grafting and Budding.—This is performed upon stocks of any sorts of the *Plum-kind* raised from the stones, sowed in autumn in beds of good earth, about two inches deep, and when the plants are a year old, they being planted out in nursery rows two feet and a half asunder, and having from one to two or three years growth, they will be in a fit order to graft or bud with the desired sorts, which is performed in the usual way, either low in the stock for dwarfs, and at several feet height for standards. See GRAFTING and INOCULATION. Observing, that when the first shoots from the graft or bud are one year old, those of the trees designed as dwarfs for walls, &c. should be headed down within five or six inches of the bottom, more parti-

cularly of the budded trees, in order to force out laterals from the lower eyes, so as to furnish a proper set of branches, proceeding regularly from the bottom of the tree, to cover every part of the wall and espalier. But as to standards, their first shoots may either be suffered to run and branch in their own way, or headed to a few eyes, if it shall seem necessary, to force out lower laterals to give the head a more regular spreading formation; afterwards, let them all take their own growth.

When the trees thus raised by grafting or budding are from one to two or three years old, they are of a proper size for final transplanting into the garden, &c. though trees of six or eight years old may be safely transplanted; remarking however, the younger they are planted where they are to remain, the sooner and more firmly they will establish themselves, and form for bearing.

By Layers.—This is performed on the young wood, any time from November till March, chusing the last summer's shoots, and lay them by slit-laying; in one year they will be rooted, they must then be separated, and planted in nursery-rows, and trained either for dwarfs or standards, as may be required.

The double-blossom *Plum*, the two striped varieties, and stoneless kind, are all propagated by budding or grafting upon any kinds of *Plum-stocks*, either for dwarfs, or half or full standards.

And the *Bullace-tree* and *Sloe-bush* or *Black-thorn*, are propagated by sowing the berries or stones an inch deep in a bed of common earth in autumn; and the *Sloe-tree* also abundantly by suckers from the root.

Observe however, that to continue the different varieties of the *Bullace tree* distinct, they must be propagated by budding, grafting, or laying.

Planting them in the Garden, &c. and general Culture.

The season for planting all the sorts of *Plum-trees* is any time in open weather, from the fall of the leaf in November until March.

The trees of all the varieties will succeed in any common soil of a garden or orchard, and in any open exposure; allot however some of the best sorts for walls and espaliers, observing those for walls should generally have an east or west aspect, or even a south wall for some of the choicest sorts; and some may also be planted against a north wall, to furnish some late fruit: and those for espaliers

liers may be planted around any of the open quarters, as may also the standards.

First of planting and managing the trees designed for walls and espaliers.

Plant the wall and espalier trees eighteen feet distance, though if the walls, &c. are rather low, twenty feet distance will be requisite, in order that in default of a proper height, of walling, there may be more scope to train the branches horizontally.

Observe, if the trees thus planted are quite young, being only of one year's shoot from the grafting or budding, they should in March be headed down, as before observed, to four or five eyes, to force out lower horizontals, in the ensuing summer, which according as they advance in length, train them in horizontally at full length all summer long, unless you would forward a farther supply of lower branches as fast as possible, when you may pinch the young shoots in May down to a few eyes, each will throw out several laterals the same year, which train also horizontally at full length during the summer's growth; and in winter pruning, cut out only any fore-right and back-shoots, and train in all the regular ones at full length, for the branches of these trees must not be shortened only occasionally to procure wood to fill vacancies, because the branches always form fruit-spurs first towards their extreme parts, which would be destroyed by shortening, so that after having shortened the first and second years shoots occasionally, as above, and thereby procured a proper set of lower horizontals, to give the head its first form; let the whole then be trained in entire about four, five, or six inches asunder, and, according as the trees shoot, every summer train in a necessary supply of the regular shoots to fill the wall, &c. at the same time retrench superfluities and irregular growths, and train the supply of regular wood still at full length at the above distances; and thus the trees will soon cover a large space, and the same branches, not shortened, will continue bearing many years. See PRUNING.

For all the sorts of Plums bear principally upon spurs, half an inch or an inch long, arising from the sides of the branches, of from one or two to many years old, when trained always at full length; but if shortened, they would throw out a multiplicity of useless wood and hardly any fruit-spurs; therefore shorten none, except some occasional shoots to fill any casual vacancy, and always train the general branches at full length, both in the summer and winter pruning.

Observe all the sorts of wall and espalier Plum-trees should be pruned twice every year, a summer and a winter pruning, in order to retrench superfluities of each year, and all foreright and other irregular shoots, and bad wood, and to train in a necessary portion of young wood where wanted to fill vacancies or to supply the place of decayed, worn-out, and other bad branches, that may casually occur, observing the general directions for summer and winter pruning, under the article PRUNING.

Standard Plum-trees may be trained both as full standards and half-standards, budding or grafting the former six feet high, and the latter only three or four; or both kinds may be worked low in the stock, and the first shoot trained to those heights for a stem, then let them branch away and form a head.

These standards may be planted both in the garden and orchard, at from about twenty to thirty feet distance; which having had their head previously shortened in the nursery when one year old from budding, &c. If thought necessary, in order to force out lower branches to give the head a spreading form, they should now be planted with their heads entire, all but retrenching any irregularity; and should afterwards be permitted to take their natural mode of growth, except just reforming occasionally any cross placed or very crowded branches, and all dead wood.

Cherry kinds.

PRUNUS *Cerasus*, or Cherry-tree.

The Cherry was formerly placed as a distinct genus (*Cerasus*), but its characters proving the same as the Plum, and both sorts readily take by budding or grafting upon one another, it is now retained as a species of *Prunus*. There is but one species of the cultivated Cherry, but which, like the Plum, sports exceedingly in variety; there are however several species of the Cherry kind, as Common Cherry-tree—Wild Cherry-tree—Bird Cherry, &c. the first of which and its varieties is the principal species for general culture for the fruit; likewise some of the Wild Cherry; all the others are for the shrubbery and other ornamental plantations.

The species are,

¹PRUNUS *Cerasus*.

Cerasus, or Common Cherry-tree.] Grows twenty feet high, or more, garnished with oval clusters of lanceolate, smooth leaves, umbellate flowers, succeeded by clusters of roundish red fruit of different sizes and properties in the varieties.

Varieties.

Varieties.] The above species comprehends many varieties, the most material of which are the following.

Common Red Kentish Cherry.—The tree forms a spreading head, with numerous slender branches, bearing round bright-red Cherries, of a sharp acid relish, unless permitted to hang till dead ripe, when they become of a dark-red colour, and of a high flavour, is a remarkably great bearer, and proper to cultivate where large quantities are required for sale, as also profitable for private use, and if full ripe, is an excellent Cherry; ripe in July.

This variety is supposed to be the original kind, and that most of the other sorts were first raised from it.

Little May Cherry.—The tree a moderate shooter, having slender shoots and small leaves, and small, round, red fruit, valued chiefly for its early perfection; ripe end of May or beginning of June.

Common May Duke Cherry.—The tree large, spreading, and a great bearer, having large, round, dark-red, very fine eating Cherries; ripe sometimes in the end of May, but mostly in June.

Arch Duke Cherry.—The tree large, branching strong and erectly, having larger, round, dark-red fruit; ripe end of June and in July.

White Heart Cherry.—The tree is of very large spreading growth, producing heart-shaped, whitish fruit, tinged with a red next the sun; ripe in June and July.

Red Heart Cherry.—A larger, heart-shaped, red-coloured, excellent Cherry; ripe June and July.

Black Heart Cherry.—A large, heart-shaped, very dark-red, rich-flavoured Cherry; ripe end of June and in July.

Amber Heart Cherry.—A middling-size, heart-shaped, amber-coloured fruit; ripe middle or end of July.

Ox Heart Cherry.—A very large, heart-shaped, red Cherry; ripe middle or end of July.

Bleeding Heart Cherry.—A large, longish, heart-shaped, deep-red beautiful Cherry, but the tree no great bearer; ripe middle or end of July.

Hertfordshire late Heart Cherry.—A middle-size, heart-shaped, firm, good Cherry; ripe end of July and beginning of August.

Carnation-coloured Cherry.—A very large, roundish, white and red, beautiful, firm Cherry; ripe end of July.

Lukeward Cherry. A middle-sized, roundish, dark-coloured, very good Cherry; ripe end of July.

Morello Cherry.—The tree a moderate shooter, but spreading, with numerous slender branches, and a great bearer, producing large, round, dark-red fruit, having a tender juicy pulp, of a sharp acid taste; but if properly ripened in a sunny exposure, is of a rich agreeable relish. The trees being generally planted against a north wall never ripen the fruit perfectly till late in the season, but some should also be planted on a south wall, to have the full sun, where the fruit will ripen three weeks sooner, and attain a much richer flavour, and prove an excellent Cherry for the table; ripe in August and September.

Coroun, or Corone Cherry.—A middle-size, round, black, very juicy, excellent Cherry, and the tree a great bearer; ripe end of July and in August.

Double-blossomed Cherry.—The tree is of a moderate growth, and produces large, very double, pure-white flowers, of great beauty placed on long slender foot stalks; each flower being as double as any rose, rising in great abundance all over the tree, and make a fine ornamental appearance in the shrubbery and other compartments of the pleasure-ground; flowering in May, but rarely any fruit, except sometimes from some semi-double flowers.

Red-blossomed Cherry.—Having pale-red flowers.

These are all the principal varieties of Cherries proper for general culture, and trees of all the sorts are sold at the public nurseries by the above names, annexed to each variety, all of which are deciduous, and of hardy growth, will succeed in any common soil and situation, and bear well both in dwarfs for walls and espaliers, and in standards of all sorts. See their culture.

²PRUNUS Avium.

Great Wild Cherry-tree.] Grows forty or fifty feet high, having oval spear-shaped leaves, downy underneath, and umbellate sessile clusters of white flowers, succeeded by small round fruit of different properties in the varieties.

Varieties are.] Common, small, black, wild Cherry—Red wild Cherry—Larger fruited wild Cherry; ripe end of July and in August.

The trees of all the varieties of this species grow very large, and grow wild in England, &c. in woods and hedges, but are proper

per to cultivate both as fruit, forest, and ornamental trees, and are often planted in gardens, avenues, lawns, and parks, as they make a fine appearance in spring when in blossom, and bear great crops of fruit, which succeed the varieties of the cultivated Cherry, and though small, is of an agreeable flavour; and considered as timber-trees they are greatly esteemed by the cabinet-makers, turners, and some other trades, the timber being of a fine reddish colour.

The following are the Bird Cherry kinds, cultivated chiefly for ornament, the fruit being not good to eat; but being greatly coveted by the birds, have the appellation of Bird Cherry.

³PRUNUS *Padus*.

Padus, or common Bird Cherry.] Grows fifteen or twenty feet high, of a shrub-like growth, and with a spreading head, large, oblong, rough, serrated leaves, having two glands at the back of their base, and long loose clusters of white flowers, succeeded by small, round, black fruit in August.

Variety.] *Cornish cluster Bird Cherry*, having generally a taller upright stem, a more compact regular head, broader leaves, distinguished however with two glands at the back of the base like the other, and with shorter, more compact clusters of flowers, succeeded by larger red fruit.

The common sort grows wild in hedges in the northern parts of England.

⁴PRUNUS *Virginiana*.

Virginian Bird Cherry.] Grows thirty feet high, dividing into a very branchy head, having a dark-purple bark, oval, slightly serrated, shining, green leaves, having two glands at the fore part of the base, and long clusters of white flowers, succeeded by small, round, berry-like, black fruit.

⁵PRUNUS *Canadensis*.

Canada Dwarf Bird Cherry] Grows but four or five feet high, branching horizontally near the ground, and have smooth branches, broad, spear-shaped, rough, downy leaves, without glands, and long clusters of white flowers, succeeded by small, round, berry-like, black fruit; ripe in autumn.

⁶PRUNUS *Mahaleb*.

Mahaleb, or Perfumed Cherry.] Grows ten or fifteen feet high, having smooth whitish branches, small, oval, shining-green leaves, and corymbose clusters of white flowers, succeeded by small fruit.

All the above five species of the Cherry

kind arranged under this head, flower commonly in April and May, so abundantly as in a manner to cover the branches, each flower having five small petals, and twenty or more stamina, as observed of the Plums, succeeded by fruit all of the Cherry kind; ripening in different sorts from May until September; remarking however, that the fruit of two species only are esculent, *i. e.* *Common Cherry-tree* and its varieties, and the *Great Wild Cherry*; those of the other species being of a disagreeable relish.

All the varieties however of the common Cherry-tree and great Wild Cherry merit culture for their fruit; and as Cherries in general are valuable as a most refreshing fruit in the heat of summer, and for their attaining the earliest perfection for eating raw of any of our tree fruits, every good garden should be furnished with a collection of the trees of different sorts, but principally of the common Cherry and varieties.

But the double-blossom kind, &c. and all the sorts of Bird Cherry and the Perfumed Cherry are employed principally in shrubberies for ornament and variety.

The common Cherry, in all its varieties, is cultivated both in gardens for walls, espaliers, and standards, and in orchards, both in assemblage with other standard fruit-trees; and in many places whole orchards of them, in full standards, are planted, in order to supply the markets with the fruit. In gardens, however, it is proper to have a portion both as dwarfs for walls and espaliers, and half and full standards; and if some of the best kinds are planted against walls of different aspects, they will furnish a succession of ripe Cherries from May until September, besides the supply from the espaliers and standards; for the trees will bear in all exposures; but it is highly proper to have some of the earliest and other more valuable kinds against a south or south-east wall; those in the south exposures will ripen soonest, and will be succeeded regularly by the others in the east, west, and north aspects; a north wall however is very commonly allotted for Morello Cherries in particular; but as this is a most excellent Cherry when well ripened, it is eligible to allow a share of the trees a south aspect, where they will ripen sooner and in greater perfection; and those planted against a north wall will succeed them, and continue until September. However, where there is scope of ground and different

different situations, it is advisable to plant several different sorts accordingly, whereby a constant supply of ripe Cherries may be obtained for near three months.

Considerable orchards of these trees are planted in some parts, particularly in Kent, for the supply of the London markets, consisting principally of the Kentish and Duke Cherries, as being the most certain best bearers; but it is proper to plant some of all the varieties.

The Wild Cherry is always trained for standards, and planted in any open situation. Great quantities of them are planted in hedge-rows, round fields, in some of the counties round London, for the sake of the fruit to supply the markets.

The mode of bearing of all the varieties of these trees is, both on the year-old wood, and that of many years, principally upon short spurs arising from the sides of the branches, if not shortened, but if shortened they throw out wood-shoots and no fruit-spurs, therefore the branches of these trees must not be stopped, but suffered always to remain at full length.

All the sorts of these trees will prosper in any common soil, capable of producing good crops of esculent herbs and roots, grass and corn, &c.

Method of propagation and general culture.

The method of propagation for all the varieties of the Common Cherry-tree is by grafting and budding them upon stocks of the Wild Black and Red Cherry, raised from the stones of the fruit: they will, however, grow upon any sort of Cherry-stock; and they will likewise take upon Plums, though plum-stocks are not advised for general use; they will also grow upon laurel-stocks, which, however, is only sometimes practised for curiosity, suffering a small part of the stock to grow up to shew the singularity of the two sorts growing upon the same root. All the varieties will likewise grow upon the Bird-cherry, but this should only be practised when required to dwarf any trees as much as possible; which being grafted on the common or Canada Bird-cherry, are proper to plant in pots, for forcing in frames, or to plant in the borders of a forcing-frame. See FORCING FRAME. However, for general use, always use the Wild Cherry-stocks, as being the freest shooters and of longest duration, though in default of these, may use any sort of

common Cherry-stocks.—And as to the method of raising them, it is from the stones of the fruit, sowed in autumn in beds of light earth, covering them near two inches deep, they will come up in the spring; and in autumn or spring following, if the plants are strong, transplant them in nursery-rows two feet and half asunder, to remain for grafting, &c. which, when about the size of a large goose-quill or little more, they will be fit to work for dwarf trees; but for standards they must have at least four years growth, because they must be grafted at six feet height.

The grafting and budding all the sorts is performed in the usual way, though grafting is most to be recommended for general practice, as they are not so liable to gum as budded trees; and whip-grafting is the most eligible method; observing to graft or bud the dwarfs near the ground, and the half and full standards from three to six feet high: the grafted trees will shoot the same year, and the budded ones not till the spring following.

Observe, that when the first shoots from the graft or bud is a year old, those of the dwarf trees for walls, &c. must be shortened down in March or beginning April, to five, six, or eight inches long, according to their strength, to procure lateral shoots to form the head; but as to the standards, they may be shortened or left entire as the case requires. If you would have them form a spreading head, the first shoots may also be shortened to force out lower branches; after this let the branches both of the dwarfs and standards remain mostly at their full length; and whilst the trees continue in the nursery, train those designed for walls, &c. to stakes, in a proper position, and pinch young shoots in summer to procure more branches which still continue entire.

When the trees are from one or two, to five or six years old, they are proper for final transplantation into the garden and orchard, though if planted when their heads are not more than two or three years old, they will succeed much better than larger trees.

The season for planting them may be any time, in open weather, from the end of October, or beginning of November, till March.

Plant the wall and espalier trees eighteen or twenty feet distance; and if the walls are tolerably high, may plant a half or full standard

dard in the spaces between the dwarfs, that whilst these cover the bottom and middle, the standards cover the upper part of the wall.

The management of these trees, thus planted against walls, and espaliers, is principally as follows.—First, observe, that if they were planted when only one year old, from the grafting, &c. with the first shoot from the graft or bud entire, they should be pruned short in March or beginning of April, as observed in their nursery culture, to furnish lateral branches; but if they were headed in the nursery, and horizontals thereby obtained, they must not be shortened now nor hereafter, except occasionally pinching shoots to fill a vacancy, for as the fruit-spurs first rise towards the upper ends of the branches, a general shortening would not only cut away the first fruitful parts, but force out a great deal of useless wood; let therefore the necessary branches arising every year after the first heading down, be trained horizontally at full length, five or six inches asunder, and if wood is wanted pinch some adjacent young shoots in May or early in June, or shorten it in the spring following, and it will push forth two or three laterals; being careful to retrench all fore-right and other irregular-placed shoots, and continue training the regular branches still at full length, at equal distances, till they have filled the allotted space of walling or espalier; thus, by arranging the branches entire, they will soon spread considerably, and emit numerous fruit-spurs all along their sides, and in two or three years bear abundance of fruit.

Observe the bearing wood does not want renewing annually; but the same branches continue bearing several years, and only wants renewing with young wood occasionally, as any branch becomes barren or an ill bearer.

They must, however, be pruned twice every year; a summer pruning early in the season, to retrench all evidently superfluous shoots soon after they are produced, likewise all fore-right and other ill-placed shoots, and rank wood, as soon as possible; and to pinch shoots where wood is wanted, so as there may be as little pruning as possible upon the older wood, which is apt to gum by much cutting, retaining however a general moderate supply of the regular-placed shoots, to chuse from in the winter pruning, training the whole at full length: and in winter pruning, retrench any casual

worn-out branch or decayed parts, retaining young in their stead; and cut out all superfluous or unnecessary shoots, reserved this summer, not now wanted, leaving only some well-placed ones in any vacant spaces; then nail all the branches regularly to the wall, &c. still at full length. See SUMMER and WINTER PRUNING.

Observe in both seasons of Pruning, in cutting out the useless wood, always to cut every thing quite close. See PRUNING.

Likewise be particularly careful to preserve the fruit-spurs, only retrenching such as become very old, unsightly, and barren.

Standard Cherries should be planted twenty-one feet distance at least, though, if for a whole orchard, twenty-four feet, or eight yards distant every way will be requisite. Observe that the first shoots having been previously shortened in the nursery, if thought necessary, to promote lower branches to form the head, plant them now with their heads entire, except just reducing any irregular growth, and suffer them to branch every way, and shoot in length as fast as they are able, not shortening any, and all the branches will soon form numerous fruit-spurs.

Very little Pruning is required for Standard Cherries, and the less the better, as too much use of the knife causes them to gum and canker; therefore, all that is necessary is, occasionally to retrench any very irregular-growing branch, and all decayed wood.

The Double-blossomed Cherry is also propagated by grafting or budding, like the other varieties, upon any kind of Cherry-stocks, and may be trained both as dwarfs and half and full standards, to effect the greater variety in the plantations.

The Wild Cherry-tree is easily raised from seed, i. e. the stones of the fruit; though if any variety produces a larger and finer fruit than common, it may be continued by grafting, &c.—To raise them, however, from the stones, procure a quantity in autumn, when the fruit is dead ripe, and sow them in beds of light earth an inch and half deep; they will come up in the spring, and after having one or two years growth, plant them out in nursery-rows, with their tops entire; here train them up for standards, with stems six feet high, then let them branch out every way to form heads.

They may be planted out as standards in gardens, orchards, or any open grounds for

for the fruit, and in ornamental plantations of forest trees.

All the sorts of *Bird Cherry* are also propagated plentifully by the seed or stones of the fruit; sowed in the autumn in light earth, near an inch deep; the plants will rise in the spring, and in a year after should be planted out in nursery-rows two feet asunder, to remain a few years till fit for the shrubbery, &c.

These sorts may also be propagated by layers, which will readily strike root and be fit for transplanting in one year. They will also grow by cuttings planted in autumn.

The *Perfumed Cherry* is also often propagated by grafting upon any sort of Cherry-stocks, raised as before directed in the propagation of the common Cherry-tree, and may also be tried by layers.

Apricot kinds.

PRUNUS Armeniaca. Apricot-tree.

Under this head is ranged only one species, the *Armeniaca* or Apricot, a choice fruit tree, comprehending many valuable varieties of the fruit: it was formerly ranged as a distinct genus (*Armeniaca*), but is now a species of *PRUNUS*.

Class, order, and characters the same as the Plum-tree, (*Prunus domestica*)

The species is,

PRUNUS Armeniaca.

Armeniaca, or Apricot-tree.] Grows twenty feet high, with a large spreading head, having reddish shoots, large nearly-heart-shaped leaves, and close-fitting pale-red flowers, rising all along the sides of the young branches; succeeded by large roundish fruit, of a yellow and reddish colour in different varieties.

The most noted varieties of this fruit in the English gardens are,

Early White Masculine Apricot.—A small round whitish yellow fruit, ripe towards the middle of July.

Early Red Masculine Apricot.—A small round fruit, reddish next the sun, and of a juicy agreeable flavour; ripe middle or latter end of July.

Orange Apricot.—A large roundish fruit of a deep-yellow colour, tinged with red next the sun, having a firm but rather dry pulp, is however a handsome fruit; ripe beginning or middle of August.

Algiers Apricot.—An oval somewhat compressed pale-yellow fruit, is tolerably juicy

and well flavoured; ripe early part of August.

Roman Apricot.—A large, roundish, yellow fruit, firm, juicy, and well flavoured; ripe beginning or middle of August.

Turkey Apricot.—A very large, oval, compressed, deep-yellow fruit, having a firm well flavoured pulp; ripe beginning or middle of August.

Temple Apricot.—A middle-sized, roundish, compressed, deep-yellow, firm, good fruit; ripe middle of August.

Breda Apricot.—A large, roundish, deep-yellow fruit, having an orange-coloured pulp, is an excellent Apricot, and the tree a good bearer both against walls and in espaliers and standards; ripe middle or end of August.

Brussels Apricot.—A moderate-sized roundish-oval fruit, spotted with red next the sun, the other side yellow, having a deep orange-coloured, firm, high flavoured pulp; and the tree bears well against a wall and in standards; ripe middle and end of August.

All the varieties of these trees blossom early in the spring, about the end of February and in March, arising principally from the sides of the young shoots of the former year, immediately from the eyes or buds; also sometimes upon spurs from the two years old wood, and the flowers are succeeded by young fruit in April, encreasing gradually in magnitude till July and August, when they attain perfection; observing they should be gathered before they become quite ripe, otherwise they will eat very mealy and with no flavour, but being gathered as soon as one side becomes a little soft, and while the fruit remains entire and firm, they will then eat brisk and agreeably flavoured.

As these trees blossom and set their fruit early in spring, often whilst sharp frosts and cutting blasts prevail, frequently destroying most of the bloom and newly set fruit, so that they sometimes have but very thin crops, for which reason they require a sheltered warm sunny situation in this country. In favourable seasons, however, they sometimes produce five times more fruit than they can nourish or bring to due perfection, in which case the fruit is always thinned when about the size of ordinary cherries, and those thinned off are excellent for tarts.

But the trees of most of the sorts require to be trained against a warm wall, in order both to protect their early blossom and young fruit

fruit from the injuries of the weather, and to promote the more early and perfect ripening of the Apricots; they will succeed in an east or west aspect. It is, however, proper to allow the early, and some other kinds, a south wall to effect a variation in the times of ripening.

Some sorts will also bear tolerably in espaliers and standards, particularly the Breda and Brussels Apricot.

Apricots are valuable summer fruit for several different purposes. Green and young for tarts; for which purpose, being gathered before the stone becomes hard, make the most excellent tarts or pies of any fruit so early in the season. When ripe are very fine table fruit, provided they are gathered before they become soft and mealy. And being preserved in sugar is an excellent sweetmeat.

Method of propagation and general culture.

These trees are propagated by budding upon any kind of Plum-stocks.

The stocks for this purpose are raised from the stones of the fruit, sowed in the autumn in beds of light earth two inches deep; they will come up next spring, and in autumn or spring following, the plants will be fit to plant out in nursery-rows, and in a year or two they will be fit to bud for dwarfs for walls, &c. but for half standards and standards they must have three, four, or five years growth, and trained up with stems from three or four to six feet high—though sometimes the budding for standards is performed low in the stock, and the first shoot trained up for a stem.

The budding is performed in August, being careful to procure shoots for the buds from trees of the best sorts, as proved by the fruit they bear; performing the work of budding them in the usual way. See INOCULATION. The buds will not shoot till spring, at which time, before they begin to push, head down the stock a little above the bud, soon after which the buds will shoot and advance rapidly, and by autumn form a large shoot of a yard or more long, and the trees are then proper for planting out for good; observing, that whether they remain in the nursery, or are transplanted into the garden, the above first shoot from the bud must, in March following, be headed down to four or five eyes, to procure lower horizontals, as observed of the Plums and Cherries.

When, however, the trees are of one year's growth, with their first shoots or head entire, they are of a very proper size for planting out finally where they are to remain. They may be planted any time in open weather from October until the beginning of March, choosing a south wall for the early, and some other kinds to come in forward; but as those exposed to the full south sun are apt to become soon mealy, it may be proper to plant the principal supply against east and west walls.

They do not require any particular soil or compost, but will succeed in any common soil of a garden; previously trenching the borders two spades deep.

Plant them in a range close along the wall, at eighteen feet distance, with their heads entire for the present, which fasten either to the wall or to stout stakes, one to each tree, to preserve them steady until spring, when they must have their first pruning, &c.

Their management, after being planted in the garden, is as follows: in the first place observing, that if the trees are only one year old, with their first head from the bud entire, they must be headed down in the spring, as aforesaid, to four or five eyes, to force out branches below; after this give the trees water in dry weather, and they will readily push out shoots from all the remaining eyes, which in summer nail up regularly to the wall at their full length, and if any fore-right or back shoots come out, rub them off, being careful to continue the regular shoots to the wall all summer and the following winter; and in spring shorten each shoot to about eight, ten, or twelve inches, according to their strength, leaving the lowermost ones, on each side, rather the longest; this pruning short being still necessary in order to procure a farther supply of lower branches, that every part of the wall may be occupied quite from the bottom, having particular attention to preserve nearly an equal number of branches arranging on each side of the tree, and nail them close to the wall in a horizontal position, about five or six inches asunder. The summer following each horizontal will push out three or four, or more, new shoots, of which, if any rise fore-right and behind the branches, rub them off early in the season, and nail in all the regular side shoots, at full length, all summer, except it is necessary to pinch any particular shoot early in the summer to fill a vacancy as soon

soon as possible. In the winter pruning examine if there be any superfluities or irregular growths left in summer, cut them out close, and let all the regular-placed necessary shoots be shortened, though they should not now be pruned so short as in the two first years, only cutting each shoot according to its strength, from about eight or ten, to fifteen or eighteen inches long; for we may now suppose the head of the tree to be tolerably well formed, should therefore prune so as to obtain both a farther supply of wood, and a crop of fruit; and remarking, that as these trees bear principally upon the young wood of a year old, it is eligible to train in a general supply of young shoots, of each year, in every part; the same shoots producing, at the same time, both a crop of fruit and a supply of wood for next year's bearing, still remembering that the annual supply of wood must always be shortened in the winter pruning, for if left entire, they would produce only some shoots near the top, and leave the bottom naked, so as, in a few years, the whole tree would become very thin of bearing wood below, and bear only a little towards the extreme parts of the branches; this therefore determines that, in winter pruning, the shoots should always be more or less shortened according to the strength of the tree, situation and strength of the respective shoots, in order to obtain a necessary succession of young wood annually in proper situations, so as to continue every part of the tree from the bottom to the extremity, every way regularly filled therewith for bearing: observe, likewise, that as these trees bear also upon short spurs, arising upon the two years old branches, it is proper to preserve them wherever they appear, only retrenching such as project considerably fore-right; leaving all those of one or two inches long, keeping in mind however that the young shoots, of one year's growth, are the principal bearers: those produced one year bear fruit the next, and a general supply must be every year retained, and not shortened in summer, which would force out laterals from every eye, and spoil the shoots for next year's bearing; but in winter pruning a general shortening, more or less, is necessary, and the whole tree then regularly nailed to the wall.

Observe, they must be pruned twice every year, a summer and a winter pruning.

The summer pruning consists in reforming the irregularity of the numerous shoots

annually produced in this season, beginning in May or early in June, and rub off close all fore-right and back shoots, and all evident superfluities and very rude growths; retaining, however, in every part, a full supply of the regular side-shoots, as succession-wood for next year's bearing, training them in at full length, as before directed, to remain till the winter pruning, for it is of importance to leave more than a sufficiency of the well-placed shoots at this season, to have plenty in every part to chuse from in the general winter pruning. See PRUNING.

And the winter pruning comprehends a general reform among all the branches and shoots, such as the retrenching all worn out and old naked branches ill furnished with bearing wood, as they from time to time occur, to make room for those furnished with proper young shoots of the preceding summer; at the same time selecting and retaining, in every part, the best of the said shoots for next summer's bearing, cutting out close all the superfluous or unnecessary and ill-placed shoots, as well as part of the former year's horizontals in every part of the tree, to make due room to train the necessary supply of young wood at proper distances; being careful in retrenching the old wood, occasionally to prune it down either to a young shoot, or to some convenient branch it supports, and is furnished with one or more such shoots, so as every branch may also terminate in a young shoot for its leader, cutting off all small shoots arising from the sides of the main ones, and let the general supply of young wood in every part be now shortened, according to their strength, for the reasons before given. The smaller shoots cut to about eight or ten inches, the middling ones to twelve or fifteen, and the strong shoots to eighteen inches or two feet long, pruning them generally to a wood-bud, in order to obtain a shoot at the end for a leader, which will draw nourishment to the fruit. Cut out also all dead wood and cankered parts, and decayed spurs and stumps; then, as soon as one tree is pruned, let it be directly nailed, which should now be performed with great regularity, training all the branches, &c. horizontally, as strait and close to the wall as possible at equal distances. See PRUNING.

Observe, when any of these trees are of a strong vigorous growth, they should be treated according to their nature; in such case,

case, therefore, it is advisable to leave the shoots thicker, and shorten them less in proportion, that by dividing the sap among many, and a greater extent of branches, it checks the luxuriance which would take place in a smaller number.

For the more wood we cut out of a vigorous tree, and the more the shoots are shortened, the more vigorous will the tree shoot, and produce but very little fruit.

But the natural inclination of very vigorous trees should in some measure be indulged, by training as many branches as can be conveniently laid in, and shortening them but moderately, some very luxuriant ones hardly at all, which being practised two or three years, it will reduce them to a moderate growth and good state of bearing, when they may be treated in the common way.

But as the management of this tree, and the Peach and Nectarine, are nearly the same, in respect to pruning, &c. as they all bear on the young wood, we refer to that article, where full particulars of pruning and training these kind of trees are exhibited, which, for the general part may be applied to the Apricot-tree. See *AMYGDALUS Persica*.

Standard Apricots are sometimes planted, and in some favourable seasons bear tolerably, particularly the *Breda* and *Brussels Apricot*, either in half or full standards; the half standards will be more out of the power of the winds and cold air.

They should be planted in a sheltered warm situation, and their culture is the same as other standard fruit trees; they require hardly any pruning, except retrenching decayed wood, or any cross-placed or worn-out branch, and let all the others take their own natural growth.

Protecting the blossom and young fruit.—As Apricot-trees against walls blossom very early, both blossom and young fruit are very liable to injury from frost and cutting blasts; it is therefore advisable to afford occasional protection, in unfavourable seasons, to some of the forwardest and most valuable kinds, either with mats, or twigs of evergreens stuck between the branches, beginning the covering as soon as the blossom begins to expand, and continue it till the fruit are fairly set; the mats to be used on nights and bad weather, but the evergreens to remain constantly till all danger is past, observing the same methods as directed for the peach and nectarines. See *AMYGDALUS Persica*.

Thinning the fruit.—In some favourable seasons these trees set many more fruit than can attain perfection; it is therefore proper to thin them when about the size of large cherries or a little bigger, which should be done with great regularity, leaving the largest, fairest, and best situated, to grow to maturity, as directed in thinning peaches.

Those thinned off make most excellent tarts, and should always be saved for that purpose.

Laurel Kinds.

PRUNUS, Lauro-cerasus, or Laurel-tree.

Under this head are ranged two beautiful evergreen trees for ornamental plantations, viz. Common Laurel, and Portugal Laurel.

The species are,

¹*PRUNUS Lauro-cerasus.*

Lauro-cerasus, or Cherry-bay, or the Common Laurel-tree.] Grows twenty feet high or more; very branchy almost from the bottom, making strong green shoots; large oblong, stiff, shining evergreen leaves, having two glands at the back, and clusters of small white flowers, succeeded by large oblong black berries, flowering in April, and the fruit ripens in September, or beginning of October, but is not good to eat.

Varieties.] Gold-striped leaved—Silver-striped leaved.

This species and varieties are some of the most beautiful evergreens in nature; are of a fine free growth; the leaves singularly large and elegant, remaining all the year.

It is a native of the East, about the Black Sea; but is very hardy, and thrives here in any situation.

²*PRUNUS Lusitanica.*

Portugal Laurel.] Grows twelve or fifteen feet high, forming a very branchy full head, having the young branches of a reddish colour; oblong-oval, thick, dark-green, glandulous evergreen leaves, and loose bunches of small white flowers, succeeded by roundish black berries; flowering in June, and the fruit ripens in autumn.

Both these species are noble evergreens; are commonly considered as shrubs, but are of the tree kind; the Common Laurel in particular, becomes a large tree in its native soil, and the southern parts of Europe, where there are whole woods of it; both the species, however, thrive here, which, in many places are arrived to some considerable size, and are great ornaments to our shrub-beries

berries and other plantations, appearing elegantly green and beautiful the year round.

They are hardy, and rarely injured by inclement weather, except in very severe winters, which sometimes kills the young shoots and outer leaves.

They prosper in any common soil, and in any exposure; the Common Laurel in particular will grow almost any where, even under shady trees, or against fences.

Both the species are most excellent furniture for all ornamental plantations, in assemblage with the evergreen tribe in particular; and some disposed towards the fronts of deciduous plantations have also a most beautiful effect. Clumps and plantations of the Common Laurel in lawns, parks, or any out grounds, are also very beautiful; and as it prospers in almost any situation, and being a fast grower, may be employed to conceal any disagreeable fence or other unsightly object; in all of which ways they will appear most beautiful, at all seasons, with their noble large evergreen foliage.

Hedges are also sometimes formed of this tree for ornament; but where this is practised the hedge should not be trimmed with garden-shears, which would mangle and spoil the beauty of their large leaves; therefore all necessary cutting should be performed with a knife, in order to preserve the leaves entire, and thus the hedge will make a very fine appearance.

It has been hinted by some that the leaves and fruit of these trees are of a noxious quality, but so far from being poisonous, the leaves of the Common Laurel are often used in the kitchen to put into custards, &c. which gives them a most agreeable bitterish flavour; and the berries are often put into brandy.

The season for planting these trees, may be any time in open weather, from October till March or beginning of April, though October and November is the most successful season.

Method of Propagation.

The propagation of these beautiful trees is very easy, by seed and cuttings; but as cuttings is the most expeditious mode of propagation, they are most commonly raised by that method.

By Seed.—In autumn, when the seeds or berries are ripe, sow them in beds of light earth, near an inch deep, and allow them

some protection in severe frosts in winter, either by hooping and matting the bed, or covering it with any dry long litter, but let them remain uncovered all mild weather; with this care the plants will come up in the spring, giving occasional waterings in dry weather, and in the autumn or spring following, when the season is settled, plant them out in nursery-rows to remain two or three years, or till wanted for any plantation.

By Cuttings.—This is a sure and very expeditious method of raising these evergreens; the young shoots strike freely, and soon commence proper plants. In August or September, in moist weather, procure a quantity of cuttings of the same year's shoots, cutting them off from about ten or twelve to eighteen inches long, with about an inch of the old wood to the bottom of each cutting if possible, though this is not absolutely necessary: having procured the cuttings, strip off the leaves from the lower part, and then plant them in a shady border in rows six inches asunder, planting each cutting two thirds into the ground: give water in dry weather, and probably those planted in August will be rooted the same year; they, however, will be all well rooted next summer and shoot at top, perhaps a foot long by the following autumn, at which time, or in the spring after, they may be transplanted in wide nursery-rows, to acquire strength for final transplantation.

In both the above methods of propagating these trees, they may be trained either bushy, of a shrub-like growth, or trimmed up to a single stem for standards.

PSIDIUM, Guava-tree.

Two exotic trees of the Indies compose this genus, retained here in stoves for variety, garnished with oval and oblong leaves, and pentapetalous flowers.

Class and order, *Icosandria Monogynia*.

Characters.] CALIX, is monophyllous, campanulate, and five-parted at top.—COROLLA, five oval, concave, patent petals.—STAMINA, twenty or more short filaments and small antheræ.—PISTILLUM, a roundish germen under the calix, long style and simple stigma.—PERICARPIUM, a large oval baccaceous fruit, having numerous small seeds.

The species are,

Psidium Pyreiferum.

Pear-fruited Psidium] Rises with a woody thick trunk, branching twenty feet high, having

having quadrangular branches and a smooth bark, narrow, oval, obtuse, opposite leaves, and the pedunculi having one flower, succeeded by an oblong pear-shaped fruit.

²*PSIDIUM Pomiferum.*

Apple-fruited Psidium.] Grows twenty feet high; narrow, oblong, pointed leaves, and the pedunculi terminated by three flowers, succeeded by apple-shaped fruit.

These plants must be kept in pots, and always place 1 in the stove.

They are propagated by seed obtained from the West Indies; sowed in pots and plunged in a bark-bed, and when the plants are come up three or four inches high, plant them in separate pots, and treated as other exotics of the stove.

PSORALEA.

This genus furnishes some shrubby exotics for the green-house collection, garnished with pinnated and trifoliate leaves, and papilionaceous flowers.

Class and order, *Diadelphia Decandria.*

Characters.] **CALIX**, is monophyllous and five-parted, having the lower segments twice the length of the others.—**COROLLA**, is papilionaceous and pentapetalous.—**STAMINA**, ten diadelphous filaments and roundish antheræ.—**PISTILLUM**, a linear germen, subulate, long, ascending style, and obtuse stigma.—**PERICARPIUM**, a compressed pod, having one kidney-shaped seed.

The most noted species are.

¹*PSORALEA Pinnata.*

Pinnated Psoralea.] Rises with a woody soft stem, branching five or six feet high, pinnated leaves of three or four pair of narrow lobes, terminated by an odd one, and at the axillas close-fitting blue flowers with white keels. It is a native of Ethiopia.

²*PSORALEA Bituminosa.*

Bituminous trifoliate Psoralea.] Rises with a shrubby stalk, branching sparingly, about two or three feet high, ternate or three-lobed leaves of a bituminous scent; and blue flowers in close heads.—Grows in Italy and in France.

³*PSORALEA Aculeata.*

Aculeated or Prickly Psoralea.] Rises with a shrubby branching stem three or four feet high, ternate leaves, having wedge-shaped lobes, terminating in a recurved sharp point, and the branches terminated by roundish heads of blue flowers. Grows in Ethiopia.

These plants flower here every summer; the first sort greatest part of that season, and

the others in July and August; all of which are succeeded by seeds in autumn.

Keep them in pots in order for removing into the green-house in winter.

They are propagated by seeds, sowed in a hot-bed in the spring, and when the plants are two or three inches high, prick them in separate small pots, and gradually hardened to the open air, so as to bear it fully by the end of May or beginning of June.

They may also be propagated by cuttings any time in summer, planted in pots and plunged in a little heat, or covered close with hand-glasses, shaded from the sun and watered.

PTELEA, Shrub Trefoil.

The plants are of the shrub kind, consisting of two species only, one for the shrubbery the other for the stove, garnished with trifoliate and simple leaves, and tetrapetalous flowers in bunches.

Class and order, *Tetrandia Monogynia.*

Characters.] **CALIX**, is small and cut into four parts.—**COROLLA**, four oval-lanceolate spreading petals.—**STAMINA**, four awl-shaped filaments, having roundish antheræ.—**PISTILLUM**, a roundish compressed germen, short style, crowned by two obtuse stigmas.—**PERICARPIUM**, a roundish bilocular membrane, having two seeds.

The species are,

¹*PTELEA Trifoliata.*

Trifoliate Ptelea, or Carolina Shrub Trefoil.] Hath a shrubby upright stem, dividing into a branchy head eight or ten feet high, covered with a smooth purplish bark, trifoliate leaves formed of oval spear-shaped folioles, and the branches terminated by large bunches of greenish-white flowers, succeeded by roundish, bordered capsules.

²*PTELEA Viscosa.*

Viscous Indian Ptelea.] Rises with several strong shrubby stems, branching erectly twelve or fifteen feet high, having a light brown bark; spear-shaped, stiff, simple leaves; and the branches terminated by clusters of greenish flowers.

The first species is a hardy deciduous shrub, and a proper plant for the shrubbery and other ornamental plantations to encrease the variety.

The second sort being of the temperature of stove exotics, must be kept mostly in the hot-house, except about two or three months in the heat of summer, when they may be set in the open air.

The

The first sort is propagated by seed, layers, and cuttings.

By Seed.—In March, or beginning of April, sow the seed in a bed of light mould, half an inch deep; or to bring them as forward as possible, may sow them in pots, and plunge them in a moderate hot-bed, just to bring up the plants an inch or two high: give occasional waterings all summer, and protection from severe frost in winter; and in spring following plant them out in nursery-rows to acquire strength for final transplantation.

By Layers.—Perform this in autumn; chuse the young shoots, give them a small slit underneath, then lay them in the earth, and they will be rooted in a year's time.

By Cuttings.—In the spring cut off a quantity of young shoots, plant them thick in pots, which plunge in any hot-bed, or in a bark-bed, just to strike them; they will readily root, and be fit to transplant the following autumn.

The second species is propagated commonly by seeds: sow them in pots, and plunge them in a hot bed; when the plants are two or three inches high prick them in separate pots, plunging them also in the hot-bed, or in the bark-bed of the stove.

PULMONARIA, Lung-wort.

The plants are hardy, herbaceous, fibrous-rooted perennials, medical and flowery plants, rising with annual stalks, from about ten or twelve inches to a foot and half long, having oval and heart and spear-shaped leaves, and terminated by bunches of pentapetalous flowers.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, is monophyllous, five-corned, quinque-dentate, and permanent.—COROLLA, is monopetalous funnel-shaped, with a cylindric tube, and the limb half cut into five obtuse, erect, patent segments.—STAMINA, five short filaments, having erect connivent antheræ.—PISTILLUM, four germens, one filiforme style, and obtuse stigma.—PERICARPIUM, none; four roundish seeds lodged in the persistent calix.

There are about six species, some are cultivated for medicine, others to encrease the variety of the herbaceous collection.

The most material species, are,

¹PULMONARIA *Officinalis*.

Common Officinal Spotted Lung-wort.] Hath the root crowned with oval, heart-shaped, rough, white-spotted leaves, and upright

stalks near a foot high, terminated by bunches of red, purple, and blue, flowers.

It is cultivated both for medicine and for variety in the garden:—is good for disorders of the lungs, coughs, and consumptions.

²PULMONARIA *Angustifolia*.

Narrow-leaved Lung-wort.] Hath narrow, spear-shaped, hairy, radical leaves; upright stalks about a foot high, terminated by bunches of flowers, becoming of a fine blue colour.

³PULMONARIA *Virginica*.

Virginian Lung-wort.] Rises with upright stalks about a foot and half high; spear-shaped, obtuse, smooth leaves; and the stalks terminated by clusters of blue flowers.

Varieties.] With red flowers, — purple-flowered—white-flowered.

All these species flower in April and May, and the seeds ripen in June and July.

They are all perennial in root, which is of the fibrous kind; but they are annual in stalk, rising in the spring, and after having flowered and perfected seed they decay: they are very hardy plants and will grow almost any where, but delight most in somewhat shady situations.

They are propagated by seeds and by parting the roots.

By seeds.—Sow them in the spring in any bed or border of common earth, and rake them in, they will soon come up, and in July or August put out the plants either where they are to remain or in nursery beds till October, then transplanted finally.

By parting the roots.—Autumn, about August or September, is the proper time; but the sooner after they have done flowering the better; do not divide them too small, and plant the slips directly, and they will flower strong the following spring.

PUNICA, Pomegranate tree.

Two species, of the tree and shrub kind, form this genus, one a hardy fruit tree, the other a somewhat tender shrub, both of them cultivated chiefly for variety; are adorned with spear-shaped and linear leaves, and pentapetalous fine red flowers.

Class and order, *Icosandria Monogynia*.

Characters.] CALIX, is monophyllous, bell-shaped, quinque-dentate at top, coloured, and permanent.—COROLLA, five roundish erect spreading petals, inserted into the calix.—STAMINA, twenty or more short filaments having oblong antheræ.—PISTILLUM, a germen under the receptacle, single style, and

and a capitated stigma.—PERICARPIUM, a large, roundish, apple-shaped fruit, having nine cells filled with roundish succulent seeds.

One of the species *Common Pomegranate-tree*, produces a very large eatable fruit called a Pomegranate, though they seldom attain true perfection in this country.

The species are,

¹PUNICA *Granatum*.

Granatum, or Common Pomegranate-tree.] Rises with a tree stem, branching numerously all the way from the bottom, growing eighteen or twenty feet high; spear-shaped, narrow opposite leaves; and the branches terminated by large most beautiful red flowers, succeeded by large roundish fruit, as big as an orange, having a hard rind filled with soft pulp and numerous seeds.

Varieties.] Large double-flowered, remarkably beautiful,—striped-flowered.

These trees are deciduous, grow naturally in Italy, Spain, and Portugal, where they ripen fruit abundantly; in this country, however, they require a warm situation, and if trained against a south wall they will sometimes produce full-sized fruit, though it rarely ripens with any tolerable flavour; but as both the flowers and fruit make a fine appearance, a few of the trees merit culture in every good garden.

They all flower abundantly, in July, August, and September, and the fruit ripens in autumn.

²PUNICA *Nana*.

Dwarf American Pomegranate] Rises with a shrubby stem, branching four or five feet high, narrow short leaves, and small red flowers, succeeded by small fruit; begins flowering in July and continues till October.

The first of these species is a hardy tree, and may be planted for ornament in shrubberies and other plantations for the beauty of their flowers; but it is advisable to plant some also against a warm wall and train them like other wall-trees, they will generally flower more abundantly, and have a chance to ripen fruit; it should be observed as they produce their flowers always on the young shoots of the year, arising principally from those of the year before, that it is therefore proper to train in plenty of the strongest best placed shoots of each year, which in winter should be shortened to promote their furnishing a greater supply of young wood in summer for flowering; and let them be trained to the wall

at equal distances, and managed nearly as directed for peaches and nectarines, &c.

The double-flowered variety produces much larger and more beautiful flowers than the others, it is therefore in greatest estimation to cultivate for ornament.

The second sort being rather tender it is proper to plant it mostly in pots, in order to have shelter of a green-house in winter.

Both the species and varieties are propagated abundantly by layers; autumn is the proper season, chusing the young branches: give a little slit at a bud or eye and lay them in the usual way, giving occasional waterings in summer, and by next autumn they will be well rooted and fit to transplant in nursery rows for two or three years, to get strength, and then planted where they are to remain.

Those of the common sort and varieties may be trained as standards, either as half or full standards, or as dwarfs.

But those designed for walls must be managed accordingly, as directed for peaches, &c. as aforesaid.

PYRUS Pear-tree, comprehending also the Apple-tree and Quince-tree.

The Pear, Apple, and Quince, were long considered as so many distinct genera, but the botanists having discovered their characters to be alike, have ranged them all as species of the same genus; and as such we will also consider them and arrange them accordingly: they are all of the tree kind, adorned with oblong and oval leaves and pentapetalous icofandrous flowers.

Class and order, *Icosandria Pentagynia*.

Characters.] CALIX, is monophyllous, concave, divided into five spreading segments and permanent.—COROLLA, five large concave petals, inserted into the calix.—STAMINA, twenty, or more, short awl-shaped filaments, having simple antheræ.—PISTILLUM, a germen situated under the calix, supporting five styles, having simple stigmas.—PERICARPIUM, a roundish umbilicated fruit with five membranaceous cells, each having one oblong smooth seed or kernel.

Agreeable to the above characters the *Malus*, Apple-tree, and *Cydonia*, the Quince-tree, formerly considered as distinct genera, are by Linnæus retained as species only of *Pyrus*: they are certainly all of the same family, for besides their agreement in characters, all the three sorts will readily take by grafting and budding upon one another; however, as the

the Pear, Apple, and Quince, have always been considered as different sorts of fruit, each sort being of a peculiar shape and property, and each comprehending many varieties, we will arrange each species and its varieties under a separate head, viz. Pear Kinds, — Apple Kinds, — and Quince Kinds, all under the generic name *Pyrus*.

Pear Kinds.

**Pyrus Communis.*

Common Pear-tree.] Rises with an upright large trunk branching thirty or forty feet high, in some widely around, others more erectly, often forming a conical head; oval, lanceolate, serrated leaves, and corymbose clusters of white flowers from the sides of the branches, succeeded by large fruit extended at the base; of different properties in the numerous varieties.

The botanic description is—*Pyrus* with serrated leaves and flowers in a corymbus.

Varieties.] There is only one species of this tree, but it comprehends almost endless varieties, all of which bearing the above description, and all bear their flowers and fruit upon spurs, arising from the sides of the branches, of from two or three to many years old, the same branches and spurs continuing fruitful a great number of years; the different varieties furnishing fruit for use from the beginning of July until May or June next year, which, according to their times of ripening may be divided into three classes; Summer Pears, Autumn Pears, and Winter Pears; the Summer Pears ripening in different sorts from the beginning of July until the middle or end of September, and are generally fit to eat from the tree, or at least, do not keep above a week or two before they rot. And the Autumn Pears attain perfection in October, November, and December; some of which ripen nearly on the tree in October and beginning of November, others require to lie some time in the fruitery, and some will keep two months: but all the Winter Pears, although they attain to their full growth on the tree by the end of October and in November, yet they do not acquire perfection for eating till from the end of November till April and May; those of each class having different properties, some being melting, others breaking, some mealy, and some are hard and austere and can be used only for kitchen uses; but our list consists mostly of eating Pears, with a few of the

choicest hard Pears for baking; though any of the large eating Pears may also be used occasionally for culinary purposes, before they are quite ripe.

As many of the fine sorts were first obtained from France they are still continued in most catalogues by the French names; observing that the varieties of the fruit are very numerous, we shall only give a list of the most valuable, arranged in three classes.—Summer Pears.—Autumn Pears,—Winter Pears.

Summer Pears.

Summer Pears are such as ripen from the beginning or middle of July until the middle or latter end of September, and continue but a short time in perfection: some of the earliest sorts keep good only a few days before they become mealy and rotten; and very few of the sorts will last much above a fortnight; but by having different varieties the succession may be continued two months or ten weeks till succeeded by the autumnal sorts, which will continue in eating from the end of September till Christmas.

Little Musk Pear.] A small roundish yellow Pear of a musky flavour, valuable for its early perfection: ripe beginning or middle of July.

Green Chiffel Pear.] A smallish nearly oblong, light-green, Pear, melting very juicy and agreeably flavoured: ripe middle or end of July.

Red Muscadelle, or Fairest Supreme.] A middle-sized, beautiful, red-striped and yellow Pear, somewhat firm, breaking juicy and rich flavoured; ripe the end of July and beginning of August.

Fargonelle Pear, commonly so called, but is properly Cuisse Madam, or Lady's thigh.] A largish, long, pyramidal, russety-green Pear, tinged with brown next the sun, having a fine, breaking, juicy pulp, of a most delicious rich flavour; is the best summer Pear in the world, and the tree a good bearer, both in standards, espaliers, and against walls: ripe beginning or middle of August.

Cuisse Madam Pear, commonly so called, but is properly the Fargonelle.] A fine large oblong, smooth, yellowish-green Pear, sometimes reddened next the sun, having a firm pulp tolerably juicy and agreeably relished, though not high flavoured, and is apt to become mealy when full ripe; but being a large handsome fruit, and the tree a remarkable

good bearer; it highly merits culture, particularly for the supply of markets; and for which purpose it is greatly cultivated about London: ripe towards the middle of August.

Windsor Pear.] A large oblongish Pear, swelling considerably towards the crown, of a greenish-yellow colour, having a softish pulp, but soon becomes mealy: ripe middle or end of August.

This sort and the former bear a great resemblance to each other, but this is rather shorter and more swelling towards the crown.

Great Blanquette Pear.] A large roundish, yellowish-green, smooth Pear, having a soft juicy flesh of a rich flavour: ripe beginning or middle of August.

Little Blanquette Pear.] A small, roundish, smooth, yellowish-green Pear: ripe middle or end of August.

Early Russet Pear.] A middle-sized, oblong, reddish Pear, melting and replete with sugary juice: ripe about the middle of August.

Musk Robine, or Queen's Pear.] A small, roundish, top-shaped, yellowish-coloured Pear, tender, sweet, and musky: ripe middle or end of August.

Red Orange Pear.] A middle-sized globular Pear, reddened on the sunny side, the other green, melting and richly flavoured: ripe end of August.

Perfumed Pear.] A middling, roundish, deep-red Pear, spotted with brown, having a melting perfumed flesh: ripe end of August.

Orange Musk Pear.] A large, round, yellow Pear, very good if eaten from the tree, as soon as a little ripe: it ripens in the end of August.

August Muscat, or Royal Pear.] A largish, globular, whitish-yellow Pear, breaking sugary and perfumed, and one of the finest Pears of the season: ripe end of August.

Onion Pear.] A middle-sized, globular, brown-skinned, Pear: ripe end of August.

Salviati Pear.] A largish, globular, flattened Pear, reddish and yellow to the sun, and whitish on the other side, tender and agreeably flavoured: ripe beginning of September.

Red Admirable Pear.] A large globular Pear, crimson-coloured on the sunny-side: ripe in September.

Summer Bon Chretien, or Good Christian.] A fine, large, oblong Pear, beautifully reddened next the sun, and whitish on the other

side, breaking and highly flavoured: ripe beginning of September.

Rose Water Pear.] A middle-sized, globular, brownish-red, rough Pear, breaking and finely flavoured: ripe middle of September.

Summer Bergamot Pear.] A largish, round-flatted, greenish-yellow Pear, melting and sugary: ripe middle of September.

Varieties.] There are two or three varieties of this sort that differ in size, but are all of the Bergamot shape.

Orange Bergamot Pear.] A largish, round-flatted, yellow Pear, reddish next the sun, breaking and replete with perfumed juice: ripe towards the end of September.

Other Summer Pears of less note are known by the following names;—Catharine Pear,—St. James's Pear,—Crawford Pear,—Citron Pear,—Pear Piper,—Brute Pear,—Musk-drone Pear—Lemon Pear,—Green Musk Pear,—Long-stalked Blanquette Pear.

All the kinds of Summer Pears ripen on the trees fit for eating, but should be gathered before they are too ripe.

Autumnal Pears.

Autumn Pears are such that attain their full growth on the trees from about the middle or end of September till the end of October; and which after being gathered gradually mellow and improve in flavour, and will keep some a month, others six weeks, and some two months or longer; being in eating principally in October, November, and December.

Autumn Bergamot Pear.] A middle-sized, roundish, flattened, yellowish green Pear, faintly reddening next the sun, melting and of a richly perfumed flavour: ripe end of September or beginning of October, continuing good until the end of November.

Swiss Bergamot Pear.] A middle-sized, roundish, greenish Pear, finely striped with red, melting and tolerably well flavoured: ripe end of September continuing in eating till November.

Great Russet Pear.] A large oblong brown and reddish Pear, sometimes spotted, having a tender rich pulp: ripe middle or end of September.

Brown Beurre, or Beurre de Roy Pear.] A fine, large, oblong, russetty, brown and greenish Pear, very melting, juicy and sugary, and is one of the finest Pears of the autumn: ripe beginning of October and keeps good till December.

White

P Y R

White Beurre Pear.] A large, roundish, top-shaped, whitish-yellow Pear, melting, very juicy and good: ripe beginning of October and keeps till November.

Red Beurre Pear.] A large, oblong, reddish Pear, melting and very fine: ripe beginning of October.

Green Sugar Pear.] A middle-sized, top-shaped, smooth, green Pear, full of a rich sugary juice: ripe end of October, and keeps good all November.

Monsieur John Pear.] A largish, nearly round, swelling, brown Pear, with a rough skin, having a breaking delicious pulp: ripe end of October, continuing in perfection all November and part of December.

Cresane Pear.] A large, somewhat globular, flattened, greenish-yellow, ruffety Pear, hollowed at the top, is remarkably tender and sweet, and may be ranked as the finest Pear of the season: ripe end of October, keeping good till December.

Swann's-egg Pear.] A moderately large, egg-shaped, dusky-green Pear, brownish next the sun, is very juicy and agreeably flavoured: ripe end of October, continuing in tolerable perfection till near Christmas.

Verte Longue, Long Green Pear, or Autumn Mouth-water.] A large, long, very green Pear, is melting and juicy: ripe in October, and continues till December.

Marquis's Pear.] A fine large, swelling, flat-topped, greenish-yellow Pear, faintly spotted with red, having a tender good pulp; is in eating in November and December.

Grey Good-wife Pear.] A middle-sized, roundish, brownish-red Pear, moderately tender and well flavoured; is in eating from the end of October till December.

Rouffeline Pear, or Long-stalked, late Autumnal Muscat.] A large, oblong, long-stalked Pear, reddish on the sunny side, is tender and of a musky flavour: in eating in the end of October and part of November.

Muscat Fleury Pear.] A smallish globular, brownish-red, long-stalked Pear, tender and high flavoured: in eating from October till December.

Twice flowering Pear-tree.] It often produces blossom twice a year, the first in the spring, and the second in autumn, so is preserved in many gardens as a curiosity.

Other less material autumnal Pears are—Be-fideri Pear.—Dean's Pear.—Vicar's Pear.—Vine Pear.—Autumn Rose Pear.—French Bergamot.—Beurre Bergamot.—Knave's Pear.—Burnt Cat Pear.—Pound Pear, very large.

P Y R

All the autumn Pears should have their full growth on the tree, but not hang till quite ripe, which is the end of September and in October, being their season of full growth.

Winter Pears.

Winter Pears arrive to full growth about the end of October and in November, but do not attain maturity for eating until they have lain some considerable time in the house, some a month or six weeks, others two or three months or more, before they ripen, as observed below in their descriptions, so that they succeed one another in perfection generally from about December until May.

By the Winter Pears being so long acquiring perfection after gathered from the tree, many persons have thought them fit only for culinary uses; but most of the following list are very fine eating Pears, after having lain the proper time to mellow.

St. Germain Pear.] A large long yellowish-green, extraordinary fine Pear, of the melting sugary kind: in eating from December until February.

Chaumontelle Pear.] A large oblong Pear, having one side purplish the other of a whitish-green colour, is melting, of a very rich delicious flavour: in eating from December until March or April.

Martin Sec, or Dry Martin Pear.] A large, oblong, ruffety-reddish Pear, is breaking, somewhat dry, but of a fine perfumed flavour: in eating end of November, December and January.

Colmar Pear.] A large swelling, flat-topped, greenish-yellow Pear, spotted with yellow; is tender and exceedingly fine flavoured: in eating from December till January or February.

Spanish Bon Chretien.] A large pyramidal purple and yellow Pear, having many dark spots on the purple side; is a fine Winter Pear, ready for eating the end of December, continues good near two months.

Virgoleuse Pear.] A large, oblong, greenish-yellow Pear, sometimes brownish next the sun, is an excellent fruit: in eating from the beginning or middle of December until the end of January.

Dauphine Pear.] A middle-sized, roundish, top-shaped, smooth, yellowish-green Pear, having a melting, sugary, musky pulp: in eating the end of November, continuing in perfection all December and most part of January.

Winter

Winter Verte Longue Pear.] A longish, green coloured, smooth, spotted, exceeding good Pear; in eating the end of December and January, &c.

Winter Beurre Pear.] A smallish, oblong, yellowish, red-spotted, very fine Pear; ready for eating in December and January.

Winter Thorn Pear.] A large, long, pyramidal whitish-green Pear; is melting, and in fine eating from December till February.

Martin Sire, or Lord Martin Pear.] A large, roundish, irregularly-swelling, smooth Pear, red on one side, the other yellow; is breaking and of a perfumed flavour: in eating in December and January.

Winter Bergamot Pear.] A middle-sized, roundish, greenish-yellow Pear: in eating from the end of November until the spring.

Holland's Bergamot.] A large, round, greenish Pear, having a tender rich pulp: in eating from January till April.

Winter Bon Chretien.] A very large, long pyramidal, yellowish-green Pear, having often an uneven surface; is breaking, very juicy, remarkably sweet and rich flavoured, and often proves the best Winter Pear in the collection: in eating from February till April or May.

German Muscat Pear.] A middle-sized, oblong, ruffety-red Pear, having a melting rich pulp: in eating from February till May or longer.

Easter Bergamot Pear.] A large, roundish, flat-topped, greenish Pear, having many rough spots is of the breaking kind; and is in eating from February till April or May.

Winter Russelet Pear.] A middle-sized, longish Pear, red on one side, the other of a greenish-yellow, is melting and agreeably relished: in eating in January, March, &c.

St. Martial Pear.] A longish, oblong, smooth Pear, one side purple the other yellow; having a buttery rich flesh: in eating from February till May or June.

Cadillac Pear.] A very large, roundish, red and yellow Pear, having a hard, sour pulp, but is excellent for baking and other culinary purposes: in use from November or December till May.

Union Pear, or Uvedale's St. Germain.] A large, long, deep-green Pear, reddish on one side, having a hard, sour, pulp, but is excellent for baking, &c. in perfection from November or December till May or longer.

Black Pear of Worcester, or Parkinson's Warden.] A remarkably large, oblong,

dusky brown, rough Pear, having a hard austere pulp, but is very fine for culinary uses, from November till March or April.

Double Flowered Pear.] The tree produces double flowers succeeded by a large, short, yellowish and red Pear, rather hard and austere; but is remarkably fine for baking, &c.

Other less material varieties of Winter Pears are known by the following names.—*Good Lewis*, a large longish Pear.—*Ambrette*, a large roundish Pear.—*Thick stalked Pear*, a very large roundish fruit.—*Amadot*, a middle sized oblong Pear.—*St. Austin*, a middling oblong Pear.—*Russet of Anjou*, a large roundish Pear.—*Chaffery*, a large oblong Pear.—*Iron-coloured Pear*, a middle-sized oblong fruit.—*Golden Winter Pear*, a large globular fruit.—*Villain of Anjou*, a large roundish Pear.—*Winter Russelet*, a middle-sized longish Pear.—*Carmelite*, a middling roundish Pear for kitchen uses.—*Winter Citron-shaped Pear*, for baking.—*Blood Pear*, for baking, &c.—*English Warden*, a large Pear for baking and other culinary uses.

There are many other varieties of Pears of less account, both of Summer, Autumn, and Winter kinds, that are unnecessary to insert here; and indeed it would be almost impossible to discriminate the various sorts of hard Pears, and others of little note, found in the orchards and gardens in country villages, and about farm-houses, in different parts of England, &c.

But as the varieties described in the above three lists having known merit, and are cultivated in most of the nurseries for sale, by the names here prefixed to each kind, consisting of near sixty different sorts, are more than sufficient to furnish the most extensive garden with a copious variety of Pears almost the year round.

All the varieties of this tree are hardy and will succeed in any common soil of a garden or orchard, both as dwarfs for walls and espaliers, &c. and in standards of all sorts; and in all of which modes of training they will bear plentifully: it is however of importance to allot a good wall and espalier for some of the choicer kinds, both Summer, Autumnal, and Winter Pears, in order both to forward the growth of the fruit and to improve its size, beauty and flavour: a south, east, and westerly wall are the proper exposures, and it is eligible to plant some in each of those aspects, to vary the times of ripening, though most of the Summer Pears will succeed very well in almost any aspect, and if

if some are planted also against a north-wall they will ripen later and continue the succession of any approved sorts longer in eating; but it is particularly necessary to allow all the fine sorts of Winter Pears an east or west wall, or a well exposed espalier, otherwise they will not perfect their fruit kindly in unfavourable seasons; in espaliers however that are well trained, all the sorts of Pears attain great perfection, and the espaliers may be arranged round the quarters of the kitchen-garden, or in any other free situation where the soil is of similar quality. See ESPALIERS.

Remarking, that these trees, both against walls and espaliers, should generally be allowed a great deal of room to spread, for by having full scope they will extend their branches more than twenty feet on each side of the stem, and the whole will sometimes form a spread of forty or fifty feet, with height in proportion.

Standards of some sorts of Pears are also naturally of a very spreading growth, others grow more upright.

However in all the methods of training these trees it is highly requisite to allow them sufficient room to spread to their full extent, and their branches suffered to extend themselves always at full length; for Pear-trees should never be shortened, except in the first or second year, &c. to obtain a supply of lateral branches to form a more regular spreading head, as hereafter elucidated, because as they always bear their blossom and fruit upon short spurs arising from the sides of the branches; first, however, towards the extreme parts, then by degrees all along the sides almost from every eye, that shortening would cut away the first fruitful parts, and thus by stopping their progress of shooting in length it would force out strong shoots from all the eyes, and prevent their forming spurs or fruit-buds; but being trained at full length they shoot moderately, and in two or three years naturally form short spurs of from about half an inch to an inch or two long, the same branch and spurs continuing fruitful a great number of years.

But it must be observed, that Pear-trees are generally several years, before they attain any tolerable bearing state, for the branches seldom begin to form fruit-spurs till they are from about two or three, to four or five years old; at that age, however, they sometimes begin to bear, but never any general crop till they are eight or ten years old.

Method of Propagation, and general Culture in the Nursery.

Pear-trees are propagated by grafting and budding upon any kinds of Pear-stocks; also occasionally upon Quince-stocks, and sometimes upon white-thorn stocks, but Pear-stocks are greatly preferable to all others for general use.

The numerous varieties of Pears having been first accidentally obtained from seed, and as seedlings of these varieties rarely produce the same sorts again; the approved kinds are continued and increased only by grafting or budding upon stocks raised from the kernels of any kind of Pears, as above said, or occasionally upon Quince-stocks, especially for dwarfs of any sort, as the Quince being a moderate shooter, they moderate the growth of the trees grafted or budded thereon, so as to be more easily kept within a smaller compass; and for the same reason, white thorn stocks have been used; but these being apt to render the fruit drier and stony at the core, are almost totally disused in the nurseries; and trees upon Quince stocks being of shorter duration than upon Pears, they are not now in much repute, so that Pear-stocks are the best of all for general use, both for dwarfs and standards: observe therefore the method of raising Pear-stocks is from the kernels of any sorts of Summer or Autumnal Pears; sowing them the end of autumn or early part of winter in beds of light earth covering them near an inch deep; they will come up in the spring, and in autumn, winter, or spring, following, plant out a parcel of the strongest in nursery-rows to remain for grafting and budding, which after having from one to two or three years growth here, or when about half an inch thick, or a little more or less, they will be of proper size to receive the grafts and buds.

The grafting and budding them is to be performed in the usual method, performing the grafting in the spring and the budding in summer: See GRAFTING and INOCULATION: being particularly careful to procure the grafts and buds from such trees as produce the finest fruit of the respective sorts you intend propagating.

Being however provided with the grafts and buds, proceed to graft them, &c accordingly for dwarfs and standards; observing, that those designed as dwarfs for walls, espaliers, or standard-dwarfs, be grafted or budded.

budded near the bottom; and for half and full standards, the stocks may either be previously trained up from three or four to seven or eight feet high to form a stem, then grafted near the top, or may be grafted low in the stock, like the dwarfs, and train the first main shoot for a stem the above height; all the grafted trees both dwarfs and standards will shoot the same year, but the budded ones not till the spring after; and when their heads are a year old from the grafting and budding they may if thought proper be planted out for good, or remain longer in the nursery as may be convenient.

Observe however, that the dwarfs designed for walls, espaliers, &c. whether they remain longer in the nursery or are transplanted at a year old into the garden, should have the first shoots from the graft or bud when a year old, headed down in March to five or six eyes to force out a proper supply of four, six, or more lateral branches, near the ground to furnish the wall and espalier with bearers quite from the bottom, and these will readily produce others to cover the upper part.

But standards, supposing them to be grafted on high stocks, may either be headed near the top of the stock, or permitted to run up, as the case may require, that if shortened it will force out laterals near the head of the stem, and form a more spreading full head; and if suffered to run up with the first shoots entire, they will form higher, and generally handsomer heads in the end; such standards however that are grafted or budded as low in the stock as for dwarfs, must have the first shoot trained upright at full length six or seven feet high for a stem, if for full standards, then may either top it at six feet height, to force out laterals near that part to form a spreading head as aforesaid, or suffer it to run and branch in its own way to form a more erect and higher head.

All the headed trees however, both dwarfs and standards, that being cut down in the spring, will soon branch out from all the eyes immediately below; being careful during the summer to trim off all shoots from the stem, and suffer all the top shoots to remain entire, and they will form handsome heads by the end of summer: and in autumn, winter, or spring, following, they may have their final transplantation into the garden, &c. provided it was not done before heading down.

But if obliged to retain them longer in the

nursery, let the whole be trained agreeable to the form they are designed to assume, whether dwarfs for walls and espaliers, dwarf-standards, or half or full standards, suffering the whole to branch away at full length, not shortening any after the above general heading down when a year old, except it shall seem absolutely necessary to procure a more sufficient supply of lower branches, after which however, no further general shortening should be practised to these sort of trees, for after having obtained a proper set of regular branches near the head of the stem, they will readily furnish more in their turn to encrease the head upwards.

Their Transplantation into the Garden, &c

When the trees however are from one or two to four or five years old, from the graft or bud they are of a proper growth for planting out finally; but if larger trees are required, those of six or eight years old may be safely transplanted; younger trees, however, always succeed the best, even if only two or three years old.

The season for planting them may be any time in open weather from the end of October till March; but if in autumn, or early in winter it will be an advantage.

They will succeed in any common soil of a garden, or any good fertile orchard-ground, or field, that is not copiously wet, or very stiff or stubborn, but moderately light and pliable, one good spade, at least, if more the better; preparing the ground by proper trenching one or two spades deep, as the depth of good soil admits; and to dig capacious holes for each tree at eligible distances.

First of Planting the Dwarfs and their general Culture.

The distance to plant Dwarf-Pears for walls and espaliers is not less than twenty feet, but if twenty-five or thirty, or more the better, especially if lowish walls, &c. that in default of height, there may be full scope to extend their branches considerably in a horizontal direction, as they will effectually fill that space, or even much more if allowed it them; but the above distance of thirty or forty feet appearing very considerable at first, and the trees standing so wide having a straggling appearance for several years before they approach one another to effect any uniformity, they are rarely planted at that distance, some scarcely half so much, but seldom more than

than twenty or twenty-five feet; however, it is of importance to grant these trees sufficient room; and the higher the walls the better, which is of particular advantage to Pears, evident by those growing against the ends of high buildings, as they extend themselves very considerably every way, as before observed, and their branches requiring to be trained constantly at full length, in which they will emit fruit-spurs all the way along their sides; therefore they may be planted at least from twenty-five to thirty feet distance, and in each interval may plant a cherry, or any other moderate-shooting fruit-tree, to fill the vacancy, and bear a few years, till the Pears advance in growth; and according as these approach one another, cut the others away by degrees, so as at last the Pears may occupy the whole space. Having however fixed on the distance, and the holes dug, and the trees ready, let them be planted in the usual way, and all with their heads entire, at least for the present. See PLANTING.

The trees being thus planted, their general management, with regard to training and pruning, is nearly as follows.

Observe, in the first place, that if the young trees thus planted are only one year old from the graft or bud, having their first shoots of a year-old entire, these should in the spring be headed down to five or six inches, as directed in their nursery culture, to force out lower horizontals; but if they were previously headed in the nursery, as we advised, and having thereby thrown out laterals to form a regular set of horizontals, consisting of six or more regular branches near the bottom, they should not now be shortened, but trained to the wall or espalier at full length horizontally, preserving an equal number on each side five or six inches asunder, they will readily emit a further supply of horizontals to cover the wall, &c. regularly upward, and at the same time as being not shortened, they will gradually form themselves for bearing, as every shortening of the branches of these trees retards their bearing a year at least; if however there is a want of branches, some of the middlemost may be pruned short, and trained upright. According as the trees shoot in summer, train in a farther supply of all the regular shoots in every part where they occur, at full length, unless it shall seem necessary to pinch some strong shoots to obtain a greater supply of horizontals the same year, in order to furnish the head as soon as possible; at this time how-

ever, displace all fore-right and other irregular growths of the year, continuing the supply of regular shoots close to the wall, as they advance in length during their summer's growth. And in the winter pruning, examine the supply of shoots retained in summer, selecting all those that are well-placed and properly situated for training in, to increase the number of horizontals regularly on each side, which leave wholly entire, and at the same time retrench any superfluities and ill-placed shoots omitted in summer; then let the whole supply of regular horizontals in every part be trained in straight and close to the wall and espalier, horizontally and equally on both sides of the tree, every branch at full length, five or six inches asunder, as aforesaid. See WALL and ESPALIER TREES, PRUNING, &c.

Another method sometimes practised in training these trees for walls and espaliers is, that after their first heading down, and having thrown out several laterals, select three of the strongest and most regular-placed of them, one on each side and one in the middle, nail the two side ones horizontally at full length, and the middle one upright; next year the tree having produced a further supply of shoots, add two or four of them as side-horizontals, arranging them on each side of the stem as the two former, training the middle shoot still in an upright direction; observing, however, if it should not furnish horizontals low enough, it may be shortened so as to make it throw out shoots at any requisite height, continuing the middle one always upward for a stem, and the side ones horizontally for bearers.

By either of the above methods of training these trees, continue every year increasing the number of horizontals, till the allotted space of walling and espalier is regularly covered with bearers at equal distances, still continuing them all at full length in all future training, as far as the scope of walling, &c. will permit; and they will all naturally form fruit-spurs at every eye, almost their whole length, and the same branches continue in a fruitful state a great number of years.

In the general training of these trees, let it always be remembered, that all branches trained in for bearers must never be shortened, because, as we before observed, their fruit-spurs being generally produced first towards the end, then gradually along the

sides of the branches, of from two or three to twenty years growth or more, so that there is no need of shortening to procure a new supply of bearing wood annually, as in peaches, nectarines, and such other trees as bear fruit upon the young wood only; but in Pears the same branches not only continue for years in a bearing state, but become every year more and more fruitful even to a great age, if not retarded and spoiled whilst in training by shortening, as is very often the case; for shortening these sort of trees, both stops their progress of growth and bearing, by reducing the length of the branches considerably, and cutting away the first fruitful parts, as they generally bear fruit at or near the extremity; and by reducing their length it forces out numerous, strong, useless shoots from the eyes below, at the places where fruit-buds would have been otherwise formed, and instead thereof crowd the tree with a great redundancy of unnecessary wood, and but little fruit; but by training the bearers from the first at full length, and continued so as far as the allotted space will possibly allow, they not only sooner fill the space of walling, &c. but emit fruit-buds from almost every eye, and bear abundantly.

When the trees have once thus filled the wall or espalier with branches, they need but very little farther supply for many years, and that only occasionally, according as any worn-out or decayed branch occurs, and wants renewing with young wood. See PRUNING.

But two prunings every year are requisite to preserve their regularity and bearing state, a summer and a winter pruning.

The summer pruning should be begun in May, or early in June, and rub off all the superfluous and unnecessary shoots of the year, and all fore-right and other ill-placed shoots, retrenching them quite close, being careful to leave the terminating shoot of every horizontal or bearer entire; and reserve here and there a well-placed shoot towards the lower parts in particular, where there are any apparent vacancies, or if none, it is proper to retain some shoots as above, till winter pruning, and if then not wanted, can be easily retrenched, training them in for the present at full length.

The winter pruning may be performed any time from the fall of the leaf until March; in this pruning examine the branches in general, and see if they are any where too much crowded, or are trained irregularly;

and if they are, let them be regulated as they may require; at the same time examine if there are any vacancies; and in which case train some contiguous shoots reserved in the summer dressing, to supply the deficiencies; all other shoots trained in last summer, not now wanted to supply any vacant space, must be cut clean out close to the branches, being careful still to preserve the terminating shoot of every branch entire, likewise all the fruit-spurs in every part, and fasten in all the branches regularly at full length.

But in winter-pruning old trees however, decayed and worn-out branches will sometimes occur; be careful therefore to cut out all decayed wood wheresoever it appears, training young, if possible, in its stead; likewise where any branch, either through excessive age or bad management, is become barren or worn out, let it either be retrenched to some eligible lower young branch or shoot, or may previously have young bearers in training a year or two or more from the bottom between the main horizontals, which is eligible enough in old trees, when there is any apparent vacancy happening either by decayed wood or worn-out branches, and according as the young ones assume a bearing state, retrench the bad wood, and train the young supply in its place; in this case look always well to the bottom of your trees, and if any good shoots offer where there is an appearance of a vacancy like to happen, train them up between the main branches to be advancing to a bearing state, to be ready when wanted.

Where any of the choicer sorts of these trees have, through great age or bad culture, become infirm, their branches in general worn out, and not furnished with bearing wood, we should endeavour to renew them with young bearers, by heading the branches wholly down near the bottom; in winter or spring, they will break out in the old wood, and in the following summer furnish a large supply of strong young shoots, which train agreeable to the rules before laid down, and they will soon form a new tree, as it were, and bear plenty of good fruit.

After each winter-pruning of all these trees against walls and espaliers, they will require a general nailing, &c. let this always be done with great regularity, training all the branches horizontally as straight as possible their whole length, at equal distances. See WALL TREES, ESPALIERS, &c.

As

As to dwarf standards of these trees, see their mode of training, &c. under the article DWARF TREES.

The culture of the borders wherein these wall and espalier Pears are growing is, common digging once every year at least, and with the addition of manure occasionally in common with the other parts of the garden; though if some good rotten dung is applied every other year, and the ground well dug or trenched every winter, it will greatly promote the size and perfection of the fruit.

Planting them for Standards and general Culture.

Standards of any sorts of Pears bear plentifully in any open situation, though the fruit may not always be so large and fine as those of wall and espalier trees: summer and autumn Pears however ripen in great perfection on standards. Observe in planting them, that trees of from two or three to four or five years old, having tolerable heads, are of a proper age and size for planting, and are preferable to older trees for any general plantation. See PLANTING. And that having been trained as directed in their nursery culture, and formed heads, consisting of several branches, let them be planted with all their heads entire, except retrenching any very irregular-placed branch, but retain all the others, and suffer them to remain at full length, and plant them in the usual manner of tree-planting. See PLANTING.

In their future growth, suffer them to branch away as fast as they are able, according to nature, and they will soon form large branchy heads, suffering all their branches to remain entire, and extend themselves in length, and they will all emit numerous fruit-spurs, and bear plenty of fruit.

The general culture of standard Pears, in respect to pruning, is very trifling, and that only required occasionally, probably once only in several years; such as the retrenching any very irregular-growing branch, such in particular as grow cross-ways, and greatly incommode the neighbouring branches, also to thin such branches that are very much crowded, and confuse the head considerably; all decayed wood and suckers from the root and stem. See PRUNING, article *Pruning Standards*.

Where these standard trees are situated in a garden, having the ground well trenched every year, and occasionally enriched with dung,

they generally produce finer fruit than in orchards.

Gathering and preserving the Fruit.

The maturity of Pears, after arriving to full growth, is generally known by their changing from a green to a yellow or reddish colour, &c. and by their frequent falling from the tree, and when with a gentle twist or turn up, easily quit their hold; but those tokens are more particularly observable in summer and autumn Pears; for winter Pears being not near ripe when gathered, often require a good pull before they quit the branches.

Summer Pears ripen in succession in different sorts, from about the beginning or middle of July till the middle of September; many of the earliest ripen all at once, as it were, and continue good but a few days, either on the tree or when gathered, nor will any of the sorts keep good long; and none of the sorts should hang on the tree till full ripe, otherwise most of them will be mealy and insipid; let these sorts therefore be gathered as soon as they are arrived to full growth, and just begin to colour and discover maturity, but before they become soft and mellow; observing that for family use, they may be gathered from the tree according as they attain perfection; but let the general crop of each sort be always taken down before they ripen fully, and lay them in any dry room; none of the kinds will keep long, some only a few days, and scarcely any of them a fortnight, though from different varieties ripening at different times, the succession is continued for eight or ten weeks.

Autumn Pears ripen in different varieties, from about the middle of September till the end of October; some of the forwardest ripen eatable on the tree, others requiring to lie some time after being gathered before they acquire perfection. Let the different sorts of this class of Pears be gathered according as they arrive to maturity; those designed to keep some time should be gathered just when they have attained full growth; their maturity or full growth on the trees is known by their frequent dropping, and by their readily quitting the tree on being handled: gather them in dry weather, and lay them in a dry close room, or in baskets, each sort separate; they will thus gradually mellow, collect rich juices, and delicious flavour.

Winter Pears attain their full growth on the trees about the end of October or beginning of November, but the eatable kinds do not acquire maturity for eating on the tree, nor for some considerable time after they are gathered, some probably in a month, others two or three, and some more, and some sorts not till spring following, and often continue in perfection till summer, as is noticed in the description of the different sorts of winter Pears; but the baking kinds may be used any time from November during their continuance.

All the Winter Pears however should be indulged with as full growth on the tree as the weather will permit, even until the end of October or first or second week in November, for the later kinds, if the season continues mild; be cautious however to get them gathered before attacked by much frost.

In gathering all sorts of Pears for keeping, always chuse dry weather, and when the fruit is also quite dry.

The method of gathering these fruit is to pull one and one by hand, by a gentle twist, or turn upward, and if they readily separate, it is a sign of full growth, more particularly the summer and autumn Pears; being particularly careful in gathering not to bruise them, and let each sort be kept separate.

According as they are gathered, carry them directly into the fruitery rooms, where those intended for long keeping, such as the late autumnal and all the winter Pears, should be previously laid up in heaps, and covered with cloths, in order to promote a perspiration, and discharge the watery moisture, which prepares them for keeping, as well as improves their flavour: this fermentation or sweating will be effected in a week or fortnight, when they should all be wiped dry with a woollen cloth; then let a quantity be deposited upon the shelves of the fruitery, to remain for first eating; others, for longer keeping, pack up in baskets, thickly lined within with straw, then some thick paper; and having filled the basket with the Pears, cover them down also with paper, then a good thickness of straw over all, fastening the whole as close down as may be, tying a label, with the name of the fruit and time of ripening, to each basket, and then place them in a close warm room; they will thus succeed those on the shelves for use, and keep good a long time; and if some are also put into

large earthen jars, plugged and rofined down perfectly close to exclude the external air, they will keep a long time sound, especially the latest sorts, which will keep till May or June.

They should be occasionally looked over, to remove all such as assume any tendency to decay, before they spread the putrefaction to the adjacent fruit; this should be properly attended to at intervals, to those on the shelves or any where in the open fruitery in particular, as they are more liable to putrefaction, and can be easily examined; but those packed up in close baskets, &c. are not so easily observed, nor will they require it so often; it is however proper, after some considerable time, to look them over.

Apple Kinds.

PYRUS Malus.

The Apple-tree (*Malus*) being now considered as a species of *Pyrus*, as formerly observed, we have arranged it accordingly under that head, together with all its varieties, which are exceedingly numerous in the difference of the fruit: some for eating, others for baking, boiling, cyder, &c. and may be said to be the most valuable fruit in the world for its various æconomical uses, and long continuance in perfection, which, in different sorts, is the year round.

Glass, order, and characters, are the same as the *Pyrus Communis*.

Of the Apple kind there may be reckoned two species, viz. Common Apple-tree, comprising many varieties—Sweet-scented Virginian Crab, two varieties.

The species are,

PYRUS Malus.

Malus, or Common Apple-tree.] Grows twenty or thirty feet high, having oval, serrated leaves, and sessile umbels of whitish-red flowers, succeeded by large, roundish, and oblong fruit, concave at the base.

Varieties.] The varieties of this species are amazingly great, in respect to the differences of the fruit; and the botanists contend that the Wilding, or Crab-Apple of the woods and hedges, is the original kind, and from the seed of which the cultivated Apple was first obtained; whose varieties, no doubt, are multiplied to some hundreds, in different places, having been all first accidentally obtained from the seed or kernels of the fruit, and the approved sorts continued and increased by grafting upon Crabs or any kinds of Apple-stocks; but although the number of different varieties is very considerable, there are not

not above forty or fifty sorts retained in the nurserymen's catalogues as principal fruit, which however is fully sufficient to furnish a supply of Apples all the year. The different varieties arrive to full growth in successive order, from July till the end of October; the summer kinds, that ripen before the middle of September, are many of them in eating immediately from the tree, and do not keep long: but most of the autumn and winter kinds, that ripen from the middle or end of September till the end of October, improve in perfection after being gathered, as they lie in the fruitery; and many of the winter kinds in particular keep good many months, even until the arrival of Apples next summer.

The most noted varieties are generally known by the following names, &c.

Genniting, or June-eating Apple.] A small Apple, oblong and roundish in different varieties, of a most agreeable flavour, and valuable for its early perfection, being in eating sometimes in June, against a wall, but ripens principally in July.

Margaret Apple.] A middle-sized, oblong Apple, one side tinged with red, the other pale green, and is highly flavoured; ripe for eating in July and August.

Common Codlin.] A largish, irregular, greenish-yellow Apple, tinged with red, valuable for its early growth, being fit for many culinary purposes, from June till August and September, and is also a tolerable good eating Apple when arrived to maturity: ripens fully in August, becoming of a bright yellow and red colour.

Kentish Codlin.] A large, longish, irregular Apple, excellent for culinary uses, in August and September.

Summer Pearmain.] A middle-sized, oblong, fine, red-striped Apple, good for eating and culinary uses: ripe in August and September.

Scarlet Summer Apple.] An oblong, deep-red, beautiful Apple, for eating and kitchen purposes, in August and September.

Summer Calville.] A large, fine, summer Apple: ripe end of August and September.

Quince Apple.] A small, roundish, quince-shaped, russet and yellow Apple; ripe for eating in September.

Summer Rembource.] A large, handsome, variegated red and yellow Apple: ripe in August and September.

Loan's Pearmain.] A middle-sized beautiful Apple, having one side finely reddened, the other variegated also with red: ripe in September and October.

Royal Pearmain.] A large, oblong, beautifully reddened Apple, for eating and culinary uses: ripe in September and October.

Red Autumn Calville.] A moderately-large, oblong, fine-red Apple, of a vinous aromatic flavour: ripe in autumn.

White Autumn Calville.] A large, oblong, fine-eating Apple: ripe in autumn.

Golden Russet.] A roundish, middle-sized, russet-yellow, good eating Apple: ripe about autumn.

Golden Renette.] A middle-sized, roundish, beautiful, red and yellow Apple, having a firm fine-flavoured pulp, excellent both for eating and baking, &c. ripe in October, and continues till spring, if packed up close.

Golden Pippin.] A small, roundish, and oblong, beautiful-yellow Apple, firm, and admirably fine flavoured: ripe in October, and may be kept till the spring.

Courpendu, or Hanging Body.] A large, oblong, handsome Apple, red next the sun, the other side pale, and generally hangs downward: in eating in autumn and part of winter.

Grey Leadington Apple.] A longish, moderately large, greyish-green, very fine Apple, being a most excellent table fruit: ripe in autumn and part of winter.

Aromatic Pippin.] A middle-sized, roundish Apple, one side russet-coloured, the other yellowish, is of an agreeable aromatic flavour: ripe for eating in October, keeping good a long time.

Violet Apple.] A largish, oblong Apple, one side reddened, the other variegated, having a firm sweet pulp, flavoured like violets: ripe in October, &c.

White Renette.] A large, roundish, whitish-green Apple, having a firm sugary pulp; good both for eating, and for baking and boiling: ripe end of October, continuing good till January.

Renette Grise.] A roundish, middle-sized Apple, grey-coloured on one side, the other tinged with yellow; in fine eating from October till Christmas or longer.

Winter Pearmain.] A moderate-sized oblongish Apple, red on one side, the other variegated red and yellow; is tolerable for eating, but very good for boiling: ripe end of October, continuing good all winter.

Kentish

Kentish Pippin.] A large, oblongish, whitish-green Apple, good for eating, but particularly adapted for the kitchen uses, from October till spring.

Nonpareil Apple.] A middle-sized, roundish, somewhat-flatted, dusky-russet-green Apple, having a firm pulp, replete with a sharp agreeable juice; a most excellent winter fruit for the desert; in eating from November or December until May.

Large Nonpareil.] A large, round, light-russet and yellowish Apple; is a fine handsome fruit, but does not continue in perfection so long as the common Nonpareil; in eating from November or December till March.

Holland Pippin.] A large, oblong, greenish Apple, having the eye pretty much sunk; is tolerable for eating, but is in great estimation for culinary purposes, from October until March or April.

Monstrous Rennette.] A remarkably-large oblong Apple, one side red, the other green, valued chiefly for baking or boiling; in November and December, &c.

None Such Apple.] A roundish beautiful Apple, being finely tinged with red on one side; is highly flavoured, and excellent both for eating and culinary uses: ripe about autumn, and continues till the end of December.

Royal Russet.] A fine, large, roundish-oblong, deep-russet-coloured, rough Apple, having a soft, yellowish pulp, of a mild flavour, and is admirable for all culinary uses in particular; is in perfection from October or November until April.

Embroidered Apple.] A moderately-large, beautiful Apple, adorned with broad red stripes; is a middling fruit, both for eating and kitchen purposes, and is in perfection in winter.

Wheeler's Russet.] A middle sized, roundish-flatted, russet-coloured, and yellowish Apple, having a firm, brisk, agreeably relished pulp, both for eating and culinary uses, and is in perfection all winter and spring.

Pile's Russet.] A smaller, middle-sized, oblong-oval Apple, russet-coloured on one side, green on the other, having a very firm flesh, of a sharp acid relish; is by some esteemed for eating, but is in high repute for baking, continuing in perfection all winter until April or May.

Stone Pippin.] A pretty large, whitish, very hard Apple, having a sour unpleasant pulp eaten raw, but is in good estimation for

baking; is in perfection all winter, spring, and great part of summer.

Barnard's Baking Apple.] A very large, fine, baking Apple, in perfection in winter, and keeps good all summer.

Kitchen Rennette.] A large handsome Apple, in high repute for all culinary uses: in perfection all winter.

The above varieties being the most approved sorts, they are cultivated in most of the nursery-gardens for sale.

The following are less material varieties of eating and culinary Apples mentioned in some fruit catalogues,—Summer Russet, a roundish, russet-coloured Apple—Summer Pippin, a roundish yellow Apple—L'Api, a small bright-red Apple—Transparent Apple, having a pellucid pulp—Virgin Apple, long and beautifully red—Anise Apple, longish, and flavoured like aniseed—Gilliflower Apple, middle-sized, and delicately reddened—Salmon Apple, longish, red, and yellow fruit—Margil Apple, middle-sized, ridged, and red-striped—Kirton Pippin, roundish, and often cracked—Lemon Pippin, small, roundish, yellow fruit—Aclemy Russet, a roundish, russet-coloured Apple—Gray's Pippin, large, roundish, grey, and green Apple—Winter Greening, a very large green Apple—Black Pippin, a large dark-green Apple—Partridge Apple, a large kitchen Apple—Lord Islay's Pippin, a middling roundish Apple—Spencer's Pippin, a middling, round, brownish and yellowish-green Apple—Winter Pippin, a roundish firm Apple—Costard Apple, large, irregular, and red striped—Winter Rambour, a large, round, red Apple—Cat's-head Apple, very large, for culinary uses. Of the above, the first five or six sorts are forward Apples, and all the others are autumn and winter fruit, and most of which may be used occasionally for eating and kitchen uses.

And of Cyder Apples, the following are the principal sorts—Redstreak Apple—Royal Wilding—Everlasting Hanger—Gennet Moyle—Whitfour Apple—John Apple—Woodcock Apple—Herefordshire Underleaf—which, with many others, are well known in the cyder counties, as Devonshire, Herefordshire, &c.

To the above lists may also be added the following varieties, being all off-spring of *Pyrus Malus*.

Fig Apple.] Having been formerly supposed that the trees produced fruit without any previous

vious visible flower, like the Fig-tree, it obtained the name *Fig Apple*; but the fact is, the tree certainly produces flowers, that are visible, which however are almost apetalous, or without petals, so are not conspicuous like those of the other varieties, but are nevertheless furnished with the generative organs, succeeded by proper fruit.

Paradise Apple.] A low weak-shooting tree, of a shrub-like growth, produces small fruit of no value, so is retained in some gardens for variety, and is sometimes used as stocks on which to graft other Apples, to render them of a very dwarfish growth for small gardens, and for planting in pots for curiosity.

Dutch Paradise Apple.] Grows a little stronger than the former, and is often used for stocks to graft upon to form dwarf trees for small gardens.

Wilding, or Crab Apple.] The tree grows more than twenty feet high, producing small, roundish, and oblong yellow fruit, intolerably sour, harsh, and disagreeable to the taste, so are used only for making verjuice. The trees of this variety grow wild in England, &c. in woods and hedge-rows, and are rarely cultivated in gardens, except for stocks on which to graft the cultivated Apples, for which purpose they have great merit, as trees grafted on Crab-stocks are generally very hardy and durable; sometimes, however, a few plants are introduced in the shrubbery plantations for variety, and are employed by the farmers for making field hedges, as being of quick growth, soon run up, and form a hedge expeditiously. See HEDGES.

Thus far terminates our list of the varieties of this great species *Pyrus Malus*.

There are however, besides the above, many other varieties of less value, but those of the above list are the generally known approved sorts; all the varieties, good and bad, are the off-spring of this one species (*Pyrus Malus*), the trees of all the sorts having oval sawed leaves, and sessile umbels of flowers, appearing in April and May, upon short spurs on the sides and ends of the branches, succeeded by fruit soon after, growing to perfection in different sorts, from July until the end of October, as before observed; those however that ripen before the middle of September keep but a short time, some of the forwardest probably not above a fortnight, others a month, or but little more; but the winter kinds continue in succession several months, and if a quantity of the latest are packed up close in baskets, lined with straw, to exclude the air,

they will continue sound and good till next summer.

The following species and variety are American shrubs, retained here in shrubberies for diversity.

²*Pyrus Coronaria.*

Sweet-scented Crab of Virginia.] Grows twelve or fifteen high, having angular, serrated leaves, pedunculated umbels of whitish-red sweet-scented flowers, succeeded by small round Crabs, remarkably four and austere.

Variety.] Evergreen Virginian Crab-tree.

Both the varieties are continued distinct by grafting, or by layers or cuttings.

General Observations on the common Apple-tree.

The trees of all the varieties of the Common Apple bear well in any mode of training, such as in espaliers, against walls, and all kind of standards; they however are rarely indulged with walls, as all the sorts of Apples attain full perfection without that aid, the walls being commonly reserved for such tender fruits as stand more in need of their assistance; in espaliers, however, it is eligible to have a collection of the choicer sorts, as in this mode of training the fruit generally attain greater perfection as to size, beauty, and flavour, than in standards; but all the varieties likewise acquire good perfection on standards of all sorts, though in a less degree; and it is from common high standards that the general supply of Apples is obtained for common use, and for the supply of markets, making cyder, &c.

In espaliers the trees may either be arranged by themselves, or in assemblage with Pears, &c. alternately, to effect the greater variety, being generally arranged around the outer boundaries of the quarters of the kitchen-garden, in the borders verging the main walks; but some may also be arranged in any other department, either for the sake of variety or convenience. See ESPALIERS.

And in common standards they may be both disposed in ranges thinly in the garden, and formed into orchards, according to the supply required; and in the cyder counties they plant them out in large fields, in wide ranges, to admit of having crops of corn, &c. between; but in common orchards they are planted about thirty or forty feet distance, and the ground is generally laid down in grass. See ORCHARDS.

Dwarf standard Apples are sometimes raised, a few for variety or curiosity, and if

if properly trained, will bear in very great perfection. See DWARF TREES.

The mode of bearing of all the varieties of Apples is principally upon short spurs, issuing from the sides of the branches of from two or three to many years old, as observed of Pears and plums, &c. formed first towards the extremity of the branches, then by degrees along the sides, provided the branches are always trained at full length, as advised for other trees that bear chiefly upon spurs, as shortening promotes luxuriance, and forces out numerous strong wood shoots in the places where fruit spurs would have been formed; but being trained always entire, they assume a moderate growth, and gradually emit natural spurs in every part; and as the same branches and spurs remain fruitful many years, determines, that in the general course of training and pruning these trees, we should not shorten their branches, except occasionally in the first and second year after grafting, if thought necessary, to force out lower laterals to give the head its first proper form; afterwards, permit the branches to extend generally at full length, both in espaliers, &c. and all manner of standards, and thus they will all soon form a bearing state.

Apple-trees often begin bearing at two or three years old, and at six or eight will bear in tolerable plenty according to their size.

Method of Propagation, &c.

All the varieties were first accidentally obtained by raising them from the kernels of the fruit, but we cannot depend upon seedlings to continue the same sort of fruit.

Grafting therefore is the mode of propagation to increase and continue the different varieties the same; performing it upon Crab, or any kind of Apple-stocks, raised from kernels, both for dwarfs and standards; also upon Codlin and Paradise Apple-stocks, raised from cuttings and layers, when designed to have espaliers and other dwarf-trees, as low as possible, to be confined within a moderate space, or for small gardens: some sorts of Apples may also be raised by layers and cuttings, particularly the common Codlin, which may likewise be raised from suckers, from the root and stem of such trees that are wholly of the Codlin kind quite from the root; however, the best general method of propagating all the kinds of Apples is by grafting upon the proper stocks, as aforesaid.

The method of raising the different sorts of stocks for the above purpose is, the Crab and Apple-stocks are raised from the kernels of the fruit; but the Codlin and Paradise-stocks must be raised by cuttings and layers, to continue them with certainty of the same kinds and moderate growth: however, as to the Crab and Apple-stocks, they may be raised from the kernels of any of the sorts, procuring the kernels in autumn or winter, either from rotted fruits, &c. or from such as have been pressed for verjuice and cyder, clearing them from the grossest of the pulp; then sow them in beds of light earth, moderately thick, either all over the bed, or in drills, covering them full half an inch deep; they will come up in the spring, when, if the season proves dry, water them occasionally, which will greatly forward the seedlings and strengthen their growth, and in autumn, winter, or spring following, they may be planted out in nursery rows, previously shortening their tap-roots, and planting them in lines two feet and a half asunder, to remain for grafting; and after having from one to two or three years growth here, they will be fit for grafting, particularly for dwarfs, or even for full and half standards, if intended to form the stem from the graft, which is an eligible method for these trees; but if the stock is to form the stem, they will require three or four years growth, to rise to a proper height, seven feet for full, and four or five for half standards.

The work of grafting all the sorts is the same as for other fruit trees, and should be performed in March, either by whip-grafting, cleft-grafting, &c. according to the size of the stock. See GRAFTING.

Having however provided proper grafts of the different sorts of Apples you intend to propagate, then let those stocks designed for dwarfs of all sorts be grafted within six inches of the ground; and standards may also be grafted low, and one shoot from the graft trained up for a stem, or may be grafted on tall stocks, inserting the grafts at six feet high: the grafts of all the sorts will shoot the same year, and by the autumn following the trees having formed little heads, consisting of two, three, or four shoots, may then be transplanted finally into the garden and orchard, or may be retained a year or two, or longer, in the nursery, as occasion may require, observing however to train them for the purposes intended, such as dwarfs for espal-

espaliers, &c. and uprights for standards, heading the dwarfs down in March following, within six inches of the graft, to force out more laterals below to form a fuller head, proceeding immediately near the bottom, so as to fill the espalier, &c. equally with branches, quite from within six or eight inches of the ground, regularly upward. But as to standards, those grafted low must consequently be trained with one shoot upright, at full length, for a stem, six feet high at least before it is topped; though if grafted on tall stocks of height sufficient for a stem, the shoots from the graft may either be headed to five or six eyes, if you would have them form a more spreading head, or may remain entire, and aspire more in height, and assume a more upright pyramidal growth: in all the modes of training, be careful to keep the stems clear from all lateral shoots, displacing all such as soon as they appear, and encourage only a proper set of branches at top to form the head.

When these trees, however, have heads from one to two or three years old from the graft, they are of a proper age for final transplantation; though trees of four or five years old will also succeed very well, and even trees of six or eight years growth may also be safely transplanted if required; but younger trees generally grow better and make more progress in the end.

The public nursery-gardens are generally well furnished with all the varieties of these trees for sale, either quite young from the graft, or trained trees of several years growth, at very moderate prices.

The season for planting them is, any time in mild weather, from the end of October till March; but if planted in autumn, or early in winter, they will fix themselves more firmly before attacked by the drought of the following summer.

They will succeed in any common soil of a garden and orchard, and in any free situation, except in low very moist land, in which they are apt to canker and soon go off: in a pliable loam they are generally very successful: be, however, in no great anxiety about the soil, any middling soil of a garden, orchard, or field, not too wet, will do very well, being properly prepared, by good trenching, where the ranges of trees are to stand.

First, of planting them in Espaliers.

Espalier Apple-trees should be ranged at not

less than twenty feet distance; but if twenty-five or thirty feet, it will be more eligible, especially for trees grafted on crab or apple-stocks, which being free shooters, their branches will readily fill that space. However, as to trees grafted on codlin and paradise-stocks, eighteen or twenty feet may be a sufficient distance; though the latter in particular, is sometimes planted only twelve or fifteen feet asunder, as being a very moderate shooter: it is, however, advisable to allow every sort full room enough, according to their growth, to have room to extend their branches always at full length; observing, as the trees having been headed down in the nursery, and thereby produced laterals forming tolerable heads of several regular branches, they should now be planted with all their said heads entire, only retrenching any very irregular growth, that do not range consistent with the intended form, and prune any broken roots, then having opened a capacious hole for each tree at the above distances, proceed to plant them in the usual manner as explained in the article *Planting*, being careful to place them with their branches ranging the way of the espalier, then let all the branches be trained in horizontally to the right and left, an equal number on each side, all at full length, five or six inches asunder, and according as they shoot in summer still continue them along entire; at the same time train in a farther supply of new shoots, to encrease the number of horizontals or bearers; and thus continue encreasing their number, every year, till the espalier is regularly filled from the bottom to top; preserving all the branches at full length, as far as the allotted space will admit, for the reasons before explained, both here and under the article *Pear*, for these and the *Pear-tree* require almost exactly the same management.

With respect to their general culture, they must constantly have a summer and a winter-pruning annually: in the summer-pruning to cut out all the superfluous and ill-placed shoots of the year, and train regular ones towards the lower parts in vacant spaces, if any, at least to remain till winter, some of which may be then wanted to fill some unforeseen vacancy, clearing out all others at this time as close as possible. And in winter-pruning examine the branches in general, if any worn-out or decayed parts appear, now is the time to retrench them, retaining young

young in their place; and if any vacancy occur, retain some contiguous young shoot to fill it: all others, not now wanted, cut clean out, close to the branches, still continuing all the branches, and any occasional supply of shoots, at full length, as far as their limited bounds will allow; then train the whole regularly, tying them in as straight and close to the railing as possible, about six inches asunder.

As the Apple and Pear-tree are nearly of the same temperature, manner of growth, and mode of bearing, they require nearly the same culture; and having treated more fully on the Pears in respect to pruning in walls and espaliers, which for the general part may be applied to Apples, we refer to that article for more particulars. See *PYRUS Communis*, *PRUNING*, and *ESPALIERS*.

In the article Pear-tree, we give some hints of another method of training in espaliers or for walls, which may also be applied to Apples if any one incline to put it in practice for variety.

Planting them in Standards.

Standard Apples may be planted both in the garden and orchard: in the garden however they should be arranged but thinly, to admit of undercrops growing freely without interruption of their spreading branches.

Observe to plant principally full standards for the general supply; and half and dwarf standards chiefly for variety, or for small gardens.

The standards having been trained in the nursery with tolerable good heads, they should now be planted with all their heads entire: if any are intended for the kitchen-garden, plant them at least forty feet distance; and for a full plantation to form an orchard, allow thirty feet distance every way. Open for each tree a wide hole, trim any broken roots, but leave all the others entire, and plant them with the usual care, as directed in the article *Planting*; and as soon as planted let every one be well staked to support them firmly upright, and prevent their being disturbed in rooting by tempestuous winds. See *ORCHARD* and *PLANTING*, &c.

Smaller growing standards such as codlins and dwarfs upon paradise stocks, may, if required, be planted only at twenty feet distance, though if there is room to allow

a greater distance it will be the greater advantage.

The standards being thus planted with their heads entire. Let them also in future advance with all their branches at full length, and for the general part take their own natural growth, and they will soon form numerous natural spurs in every part for bearing.

With respect to pruning these standards, very little is required, and that probably not once in several years, which is only the retrenching any very irregular cross-placed bough, or reduce to order any very long rambler; or when the head is become greatly crowded and confused, to thin out some of the most irregular growth, likewise all strong shoots growing upright in the middle of the head, all dead wood, suckers from the stem and root.

As to half and dwarf standards of these trees, they may be dispersed in different parts of a garden to cause variety, managing them as the full standards they will bear plentifully.

Dwarf standards on the dwarf paradise stock, being very moderate shooters, may be planted in a little compass; and they are sometimes planted in pots for curiosity, to place on a table, amidst a desert, with the fruit growing. See *DWARF TREES*.

Gathering the fruit.

Apples arrive to full growth in different sorts successively, one after another, from July until the end of October; the summer kinds continue but a short time, but the autumn and winter-apples will keep from two or three to six or eight months, in different varieties.

The summer Apples ripen some in July, but principally in August and September, and are generally fit for use immediately from the tree, both for eating and culinary uses, though some of the sorts are fit for kitchen purposes by that time they are half grown, or before, particularly the common Codlin, which boils and bakes in good perfection when quite young, and until full maturity: however, the tokens of perfection, or full growth, of the different sorts of summer Apples, is by their assuming a lively colour, emitting a fragrant odour, frequently falling from the tree, and by quitting their hold easily on being handled. They should then be gathered and laid in some dry apartment for use; they will not keep long, nor indeed is it required, for they will

will be succeeded by much better in the autumn and winter kinds.

Autumn Apples arrive to maturity in different sorts, from about the middle of September till the beginning of October: some being fit for use immediately from the tree, others require to lie a few weeks to mellow, especially for eating: their full growth on the tree is known in some by their changing of a more lively colour, sometimes imparting an agreeable smell, frequent dropping, and on being handled, by a gentle twist or turn upward, they readily quit the tree; at which which tokens of matureness, as they occur in the different sorts, they should be gathered in dry weather, and carried into the fruitery, where, with proper preservation, hereafter noticed, they will keep a long time, succeeding one another for use two or three months, or longer, in the later kinds.

Winter Apples attain full growth about the middle or latter end of October; it is, however, proper to let them hang on the trees till towards the end of that month, or some of the latest kinds even till November, if the season continues mild, but be careful to take them down before attacked by much frost; gathering them in dry weather, and carry them directly into the fruitery or any dry apartment, and there prepared for keeping as hereafter directed, whereby some may be kept sound and good for use till next June or July.

In gathering all the sorts of Apples for keeping, always chuse dry weather, and when the trees and fruit are also perfectly dry; observe likewise in gathering Apples for the table, and all kind of Apples, designed for keeping any considerable time, they should be pulled one and one by hand. Where, indeed, large quantities are designed for cyder, or any other immediate use, they may be shaken down. However, all the fine eating and culinary Apples for keeping should be carefully gathered by hand, by a gentle twist or turn upward, so as to detach them readily without breaking the fruit-buds; and as they are gathered carry them into the fruitery, &c. where, previous to putting them up for good, it will be proper to lay the choicer varieties of autumn and winter kinds in large heaps, to sweat and discharge the watery juices by perspiration, which both prepares them for keeping and improves their flavour, then, after having sweated a week or fortnight, wipe them all perfectly dry, and lay them up where they

are to remain. A quantity may be deposited on the shelves and floor of the fruitery, and closely covered down a foot thick with straw to exclude the air. And it is proper to pack a quantity of the finest winter kinds in large baskets or hampers, thickly lined round within-side with straw, covering the fruit down also closely with the same material, to exclude the external air as much as possible, whereby they will keep much longer in perfection; and if some are packed up in large earthen jars, and closely plugged down, they will keep longer still, for it is by these methods that the fruit is kept so fine and fair even until the return of Apples next year; observing, the drier and closer the room, in which the fruit is deposited in all the above methods, the better they will keep; being careful to examine the fruit occasionally, in order to pick out all that discover any tendency to corruption; those in the open fruitery are easily looked over, but those in the baskets and jars not so readily, nor indeed will they need it so much; however, it is proper, after some considerable time, to examine them, especially towards spring, &c.

In London, great quantities of the finest winter Apples are deposited in the proper season in the close warehouses in Thames-street, and other parts contiguous to the river, for sale in winter and spring, being packed closely in baskets, &c. as aforesaid, and placed in very close apartments where but little air can come; where they are kept perfectly sound and beautiful all winter, even until May, June, and July, selling them out to the retailers, and we may see them in the fruiterers shops, and in stalls in the streets, exceeding fine in May and June; but after being exposed to the open air a day or two, they shrink, lose colour, and soon decay.

It should therefore be remarked, that close packing these fruit, and keeping them in as close apartments as possible, keeping the doors and windows, always closely shut to exclude the external air, is a certain, method of preserving them long in full perfection, for the more they are exposed to the air the sooner they will decay; keep them therefore always as close as possible.

Quince kinds.

PYRUS Cydonia, Quince-tree.

The Quince-tree (*Cydonia*) was long ranged as a distinct genus, but is now a species of

of *Pyrus*. It is of the tree kind, of moderate growth, and deciduous; producing large, round, golden-yellow fruit, generally too austere and harsh to eat raw, being employed principally for culinary purposes.

Class, order, and characters the same as the Pear, &c. (*Pyrus Communis*.)

There is but one species, viz.

PYRUS Cydonia.

Cydonia, or Quince-tree.] Grows ten or twelve feet high, having slender branches and shoots, forming a low moderately spreading head, garnished with large, oval, entire leaves, very hoary underneath, and large, solitary, whitish-red flowers all along the sides of the branches, succeeded by large, round, and pyramidal golden-yellow fruit.

The botanic description is,—*Pyrus* with entire leaves and solitary flowers.

Varieties.] There are several varieties of this fruit, but the following are the most valuable sorts.

Apple-Quince.—A large, short, roundish, apple-shaped, golden-yellow Quince.

Pear-Quince.—A large, pyramidal, or pear-shaped, deep-yellow Quince.

Portugal Broad-leaved Quince.—The tree is of larger growth and with broader leaves: pear-shaped fruit, having a tenderish pulp, which bakes and boils to a fine purple colour.

Eatable Quince.—A middle-size downy Quince, having a tender pulp, and is sometimes eaten raw, though for the most part rather disagreeable to most palates.

Most of these fruit though remarkably beautiful to the eye, are too harsh and unpalatable to eat raw; their chief uses being for baking and stewing, to make marmalade, and to mix in apple pies, tarts, &c. to improve the flavour.

The trees, however, merit culture in every curious collection, some for the fruit, and others for ornament; but considered as fruit-trees, a few is sufficient to produce fruit enough to supply a large family, and may be trained both in standards and espaliers to effect the greater diversity; and as ornamental trees, they are eligible furniture for the shrubbery, &c. their numerous large flowers and golden fruit will effect a delightful variety; the flowers in spring and the fruit in autumn. Young Quince-trees are also in repute for

stocks, on which to graft and bud Pears, to dwarf them for walls and espaliers. See *Py. rus Communis* and *Stocks*.

They are very hardy, and will grow any where, but delight most in somewhat moist situations, and are therefore often planted by the sides of ponds or ditches of water.

Method of Propagation, and general Culture.

The trees may be raised from the kernels of the fruit sowed in autumn, but there is no depending on having the same or any good fruit from seedlings.

But the several varieties may be continued always the same by the propagation, by cuttings and layers; also by suckers from such trees as grow upon their own roots, and may likewise be propagated by grafting and budding upon their own or Pear-stocks raised from the kernels.

The propagation by cuttings, layers, and suckers, may be performed in autumn, winter, or spring. Chuse young wood for the cuttings and layers, which plant and lay in the common method, and they will be rooted by next autumn, then transplanted into nursery rows two feet asunder; plant the suckers also at the same distance, and here train the whole for the purposes intended: if for standards, run them up with a stem, to any desired height, from three to six feet, then encourage them to branch out at top, to form a head; and those designed as dwarfs must be headed near the ground, and trained accordingly for espaliers, or dwarf standards, as may be required, as directed under those articles.

When they have formed tolerable heads plant them out finally.

Standard Quinces, designed as fruit-trees, may be stationed in the garden or orchard, and some by the sides of any water in bye places, suffering the whole to take their own natural growth.

And as espaliers, they may be arranged in assemblage with other moderate-growing trees, such as Apples and Pears on Paradise and Quince stocks, Cherries, &c. and train them as directed for Apples and Pears in espaliers.

In shrubberies they may be planted either as full or low standards, and permit them to take their own way of growth.

Q.

QUERCUS, Oak-tree.

This famous genus comprises a noble collection of most eminent forest and ornamental trees, both deciduous and evergreen kinds obtaining in stature from twenty to near a hundred feet, in different species, garnished with oblong and mostly sinuated leaves, and monoecious apetalous flowers, of but little appearance, succeeded by oval nuts, called acorns.

Class and order. *Monoecia Polyandria.*

Characters.] CALIX, male and female, flowers separate on the same plant; the males disposed in loose amentums, each floret having a monophyllous four or five-parted calix; and the females sitting close to the buds, have monophyllous, hemispherical, coriaceous, rough, entire cups.—COROLLA, no petals.—STAMINA, many short filaments in the males, having didymous antheræ.—PISTILLUM, a small oval germen in the females, quinquefid stiles, and simple permanent stigmas.—PERICARPIUM, none; the seed, an oval nut or acorn, with a leathery univalvular shell, is fixed by its base into the calix.

There are about fourteen species, nine deciduous, and five evergreen kinds; but the *Common English Oak* is the glory of the collection, for its superior growth, and great worth and value, as a timber-tree, for bulk, strength, and duration. Several of other species have also their share of merit, some as forest-trees, others to adorn ornamental plantations.

Deciduous kinds.

Under this head, Deciduous Oaks is comprised, the common Oak of our woods and forests, and several species of North America, and some foreign parts of Europe, as France, Spain, Portugal, and Italy, as expressed in their titles; all of which are of the tree kind, deciduous and of hardy growth.

¹*QUERCUS Robur.*

Robur, or Common English Oak.] Grows from about 60 or 70 to 100 feet high, with a prodigious large trunk, and mon-

strous spreading head, oblong leaves, broadest towards the top, the edges acutely sinuated, having the angles obtuse.

Varieties.] Striped-leaved Oak, having the leaves finely striped with white.

This species grows in great abundance all over England in woods, forests, and hedge-rows; is naturally of an amazing large growth, there being accounts of some above an hundred feet stature, with wonderful large trunks and spreading heads, and is supposed will continue its growth many centuries.

²*QUERCUS Prinus.*

Prinus, or Chesnut-leaved American Oak.] Grows fifty or sixty feet high; having large, oblong-oval, smooth leaves, pointed both ways, the edges sinuated-ferrated with the sinuses uniformly round.

³*QUERCUS Pbellos.*

Pbellos, or Willow-leaved American Oak.] Grows forty or fifty feet high, having long, narrow, smooth, entire leaves like those of willow.

Variety.] Dwarf Willow-leaved Oak.

⁴*QUERCUS Alba.*

White Virginian Oak.] Grows thirty or forty feet high, having a whitish bark, long, obliquely-pinnatifid, light-green leaves, the sinuses and angles obtuse.

⁵*QUERCUS Nigra.*

Black Virginian Oak.] Grows thirty or forty feet high, having a dark-coloured bark, large, wedge-shaped, slightly trilobated leaves.

⁶*QUERCUS Rubra.*

Red Virginian Oak.] Grows about sixty feet high, having a dark-greyish bark, long obtusely-sinuated leaves, with the sinuses terminated by bristly points, and have sometimes red spotted veins, but generally dying in autumn to a reddish colour, remaining on the trees late in the season.

⁷*QUERCUS Esculus.*

Esculus of Pliny, or Cut-leaved Italian Oak.] Grows about thirty feet high, having a purplish bark, oblong, deeply-sinuated, smooth leaves, and

and long, slender, close-fitting acorns in very large cups.

⁸QUERCUS *Ægilops*.

Ægilops, or Large Prickly-cupped Spanish Oak.]

Grows seventy or eighty feet high, or more, with a very large trunk, and widely-spreading head, having a whitish bark, large, oblong-oval, deeply-ferrated, smooth leaves, the ferratures repand or bowed backward, and large acorns placed in singularly large prickly cups.

This is a noble species, almost equal in growth to our common English Oak.

⁹QUERCUS *Cerris*.

Cerris, or Smaller Prickly-cupped Spanish Oak.]

Grows thirty or forty feet high, oblong, lyre-shaped, pinnatifid, transversely-jagged leaves, downy underneath, and smaller acorns, placed in prickly cups.

All the above species of deciduous Oak, may be cultivated both as forest-trees and in diversifying large ornamental plantations; as timber or forest-trees, however, is their principal merit, but the English Oak claims the preference for general use, as the most valuable for timber, and should raise a greater quantity of it accordingly.

They are all easily raised from seed, i. e. the acorns, sowed in the autumn an inch deep. See their *Propagation*.

Evergreen kinds.

Of evergreen Oaks there are five species.—Common evergreen Oak.—Holly-leaved Oak.—Cork-tree.—Scarlet Oak,—and Moluccan or Live Oak; some as timber-trees, others for ornament, all of which retain their leaves the year round; are originally of foreign growth, mostly from the southern parts of Europe, and one from America, but have been long in the English gardens as ornamental trees, and some are arrived to a considerable growth, they being all very hardy, and prosper in any open ground.

¹⁰QUERCUS *Ilex*.

Ilex, or Common Evergreen Oak.]

Grows forty or fifty feet high, having a smooth bark, oval and oblong, undivided, ferrated, petioled leaves, downy and whitish underneath.

Varieties.]

Broad-leaved.—Narrow-leaved, and with sometimes both sorts, and other different shaped leaves on the same tree; also sometimes with sawed and prickly leaves.

¹¹QUERCUS *Gramuntia*.

Montpelier Holly-leaved evergreen Oak.]

Grows forty or fifty feet high; oblong-oval,

close-fitting, sinuated, spinous leaves, downy underneath, bearing a resemblance to the leaves of holly.

¹²QUERCUS *Suber*.

Suber, or Cork-tree.]

Grows thirty or forty feet high, having a thick, rough, fungous, cleft bark, oblong-oval, undivided, ferrated leaves, downy underneath.

This species furnishes that useful material Cork; it being the bark of the tree, which becoming of a thick fungous nature, under which, at the same time, is formed a new bark, and the old being detached for use, the tree still lives, and the succeeding young bark becomes also of the same thick spongy nature in six or seven years, fit for barking, having likewise another fresh bark forming under it, becoming Cork, like the others, in the like period of time; and in this manner these trees wonderfully furnish the Cork for our use, and of which is made the corks for bottles, bungs for barrels, and numerous other useful articles.

The tree grows in great plenty in Spain and Portugal, and from which countries we receive the Cork.

¹³QUERCUS *Coccifera*.

Scarlet, or Kermes Oak.]

Grows but fourteen or fifteen feet high, branching all the way, and of bushy growth; large, oval, undivided, indented-spinous leaves; and producing small glandular excrescencies, called kermes or scarlet grain, used by the dyers.

The small scarlet glands, found on this tree, is the effect of certain insects depositing their eggs betwixt the bark of the branches and leaves, causes an extravasation of the sap, and forms the excrescence or substance in question, which being dried, is the kermes or scarlet pastel.

¹⁴QUERCUS *Molucca*.

Moluccan Oak, commonly called American Live Oak.]

Grows about forty feet high, having oval, spear-shaped, smooth, entire leaves, and small, oblong, eatable acorns.

All the above fourteen species of *Quercus* produce flowers annually in the spring, about April and May, of a yellowish colour, but make no ornamental appearance, and are males and females separated in the same tree; the males being in loose amentums, and the females sitting close to the buds in thick leathery hemispherical calixes, succeeded by the fruit or acorns, which are oval nuts fixed by their base into rough permanent cups, and mostly sit quite close, and some on short foot-

foot-stalks, ripening in autumn, which in the common English Oak is in great abundance, and often in tolerable plenty on some of the other sorts; those of all the kinds serve for propagating their respective species; they are also excellent food for swine and deer, the common Oak in particular.

Oak-trees, of all the above sorts, may be employed in gardening to diversify large ornamental plantations in out-grounds, and in forming clumps in spacious lawns, parks, and other extensive opens; the evergreen kinds in particular have great merit for all ornamental purposes in gardens.

But all the larger growing kinds, both deciduous and evergreens, demand esteem also as first-rate forest-trees for their timber: the *English Oak*, however, claims precedence as a timber-tree, for its prodigious height and bulk, and superior worth of its wood, and is supposed will stand one thousand years before it totally decays, so is singularly valuable for all strong and durable purposes, such as ship-building, some parts of house-building, park-paling, posts, railing, and innumerable other uses. But all the other large-growing Oaks may likewise be introduced in forest-tree plantations, for Oaks in general prove valuable timber, and of all others the most durable; and besides their value as timber-trees, their annual crops of acorns prove most excellent food for fattening hogs and deer; and when the trees are felled for use, their bark, being stripped off, proves a most valuable material to the tanners for tanning leather; and after having served that purpose, is of great use in gardening for making bark hot-beds, commonly called bark-beds, being the most eligible kind of hot-beds for the culture of the pine-apple, and all other tender exotics of the hot-house temperature. Oaks, therefore, being of such superior value, every possessor of considerable estates ought to be particularly assiduous in raising woods of them, which is effected by sowing the acorns either in a nursery, and the plants transplanted where they are to remain, or sowed at once in the places where they are always to stand. See their *Propagation*, PLANTATIONS, and FOREST TREES.

All the sorts will prosper in any middling soil and open situation, though in a loamy soil they are generally more remarkably prosperous; however, there are but few soils in which Oaks will not grow; they will even thrive tolerably in gravelly, sandy, and

clayey land, as may be observed in many parts of this country of the common Oak.

Their Propagation and general Culture.

Oaks in general are raised from the acorns, which, of the common Oak, are produced abundantly all over England, and should be gathered in autumn when quite ripe, just as they drop from the trees; but the acorns of most of the foreign oaks are generally procured from abroad; and those of all the species are sold by the seedsmen.

Observe to sow all the sorts as soon after they are obtained as possible, because they are apt to sprout if they remain long out of the ground. Prepare for their reception a spot of light ground in the nursery, dividing it into four-feet wide beds, and in which sow the acorns, either in drills two inches deep, in five or six rows, lengthwise the bed, or rake the mold off the bed, the depth of two inches, into the alleys, then sow the acorns all over the surface, about two or three inches apart, press them down with the spade, and spread the earth evenly over them two inches thick.

They will come up in the spring; give them occasional waterings and weedings, and when the plants are one or two years old, it is proper to plant them out in nursery-rows: this may be done in autumn, winter, and early in the spring, taking them carefully up out of the seed-bed: shorten their tap-root, and trim off any lateral shoots from the stem, leaving their top perfectly entire, then plant them in lines two feet and half asunder, and fifteen or eighteen inches in the rows, where let them stand, with the usual nursery care, till of a proper size for final transplantation, either as forest-trees, or some for ornament, training them up as full standards, with clean straight stems and with their tops still entire.

Remark, the propagation of the striped-leaved varieties of the common Oak, and any particular variety of the other species, must be effected by grafting, as they will not continue the same from seed, so the grafting may be performed upon any kind of Oakling-stocks raised from the acorns, and train them for standards like the others.

Transplanting them finally.

When the trees of all the sorts are from about three or four to six feet stature, they should be planted out for good, though, considered

sidered as forest or timber-trees in particular, it is more eligible to plant them out finally whilst they are quite young, not advanced above from two to three or four feet in height; or if planted immediately from the seed-bed, where they are finally to remain, it may prove a greater advantage, as the quite young Oaks root more freely than older trees, and take a freer growth.

However, in this final transplantation, observe to plant those designed as forest or timber-trees, in large open tracts of grounds to form woods, placing them in rows only four feet asunder, and one or two feet in the rows, to allow for a gradual thinning. See PLANTATIONS and PLANTING.

Sometimes, however, large plantations of these trees, for woods, are raised by sowing the acorns at once in the places where they are to remain, as formerly noticed, it being the opinion of many, that the trees, raised at once from the acorn, receiving no check by removal, much outstrip the transplanted trees in growth. The method is this; the ground being prepared by good ploughing and harrowing, then, in autumn, having procured a proper quantity of acorns, draw drills across the ground four feet asunder, and two inches deep, drop the acorns therein six or eight inches asunder, allowing for some failing and for thinning hereafter, covering them in evenly with the earth the depth of the drills, or instead of drilling them in they may be planted with a dibble the same depth and distance.

As to the general management of these trees in woods or timber plantations, it is the

same as directed for forest trees in general, under the article PLANTATION, which see.

In planting any or all the species of Oak, for ornament or variety in large pleasure-grounds, some may be disposed in assemblage in any continued plantation, some in clumps, and others as single objects.

QUINCUNX Planting.

The Quincunx order of planting signifies trees planted by fives, four of them forming a square, and the fifth placed in the middle, thus . . . and may be repeated over and over in one continued plantation, with as many trees in several ranges as thought proper, and was formerly a fashionable mode of planting groves and other regular plantations in the following arrangement.

.
.
.

Somewhat of this mode of arrangement should generally be observed in the disposition of shrubby plants, &c. though not in a regular Quincunx, but something nearly in this order, which both gives the shrubs a greater scope of growth, and they shew themselves to greater advantage.

This mode of planting is also proper in the kitchen-garden, in transplanting many kind of esculent plants, such as lettuce, endive, strawberries, and even all the cabbage kinds, and many other plants which gives them a greater scope to grow than if planted exactly square at the same distance.

R.

R A C

RACEMUS, a Cluster, or mode of cluster-flowering, being a long close Cluster of flowers or fruit, consisting of one common peduncle or foot-stalk, branching and supporting many short lateral ones all along its sides, these immediately sustaining the flowers and fruit: examples of a *Racemus* are bunches

R A C

of grapes and currants, See VITIS and RIBES.

RACER, or Rutter. A cutting implement used in racing or marking out the proper width, length, and thickness of grass turfs for gardens, previous to sleaing or cutting them up for laying.

It

It is a simple but useful tool for the above purpose; consisting of a strong wooden handle about four feet long, having the point-end of an old scythe for a cutter, fixed at the lower end, with the point and edge downward, to cut into the sward; the handle should be about an inch and half thick, growing gradually thicker towards the lower end, and somewhat bending or sloping at the bottom to rest on the ground, having at the bottom part a slit longitudinally, to receive the cutter, which should be five or six inches long, placing it with the point and edge downward, as aforesaid, projecting an inch and half out at the back of the bottom of the handle in a slanting manner with the point inwards, fixing it firmly in that position, so as when pushed before you it may expeditiously cut the sward as you race it along.

Having this instrument, then mark out on the sward the width of the turf intended to be cut, which should be generally a foot wide and a yard long, and straining a line tight, strike the racer into the sward close to the line, run it along, it will expeditiously cut its way and divide the sward to a proper depth; directly place the line a foot farther, and race it out as before, and so on to as many widths as may be wanted; then race it cross ways in yard lengths: being thus raced out, the turf cutter with his turving-iron proceeds to cut them up, and he will flay them off at a great pace in exact widths and lengths as above.

RADIATUS flos, a radiated flower.—Such compound flowers as are furnished with a radius or spreading circumference. See **RADIUS**.

RADIUS, the Radius, or circumference, or outer spreading part of compound flowers, consisting of many flat florets set round the disc or middle, and spread out all around, resembling the figure of a radiant star, exemplified in *aster* or star-wort, marigold, sunflower, and many others of the compound tribe, and of which there are both single and double flowers; the singles having only one series of florets in the radius, but the doubles have from two or three to many series, continued sometimes to the very center. See **COMPOSITUS flos**.

RADICULA (from *Radix*) Radicle or Little Root, or small fibrous part issuing first either immediately from the seed, or that which terminates the stock or main root, penetrates into the soil and draws nourish-

ment for the production and support of the plant, and is the principal and essential part of every root of all vegetables.

RADIX, the Root, or lowermost part of a vegetable situated, within the ground, destined to draw nourishment from the soil for the production and support of all the other parts of the plant.

A Root consists of two parts, viz. 1. The stock or main Root (*Caudex*) that strikes downward into the earth, and puts forth radicles or fibres. 2. The radicle (*Radicula*) small thread-like roots or fibrous parts, terminating the stock or main Root, or proceeding from any part thereof, and is the principal or essential part of every Root, as it penetrates far into the soil and attracts nourishment to the main stock, thence communicated to the stem, branches, and other parts of the vegetable.

From the various structures and directions of the stock or main Root the botanists distinguish them by the following terms.

Perpendicular Root.] Descends in a strait line downwards. *Radix perpendicularis*.

Horizontal Root.] Runs in a horizontal or transverse direction along under the surface of the earth. *Radix horizontalis*.

Simple Root.] Such that is single and not subdivided.

Branched Root.] Divided into lateral branches, which also subdivide into ramifications. *Radix ramosa*.

Spindle-shaped, or tapering Root.] Is oblong, thick upwards, and tapers gradually to the lower extremity, such as common radish, carrot, parsnep, &c. *Radix fusiformis*.

Bulbous Root.] Roundish and oval swelling bulb, composed some of many succulent imbricated scales, others of many involving coats, and consist of two sorts: 1. Scaly bulbs, (*Bulbus Squamosa*) formed of many scales lying over one another, as in the lily. 2. Tunicated or coated bulbs (*Bulbus tunicatus*) formed of several tunics or coats closely involving one another, as in the tulip and onion, &c. *Radix Bulbosa*.

Tuberous Root.] A thick fleshy knob, formed of a solid lump, some roundish, others irregularly knobbed, and some oblong, composed either of one single knob, or several collected into bundles; examples of the tuberous rooted tribe are the potatoe, Jerusalem artichoke, anemone, pæony, orchis, flupendula, and hemerocallis; the turnep, carrot,

carrot, and parsnep, may also be considered of the same kind, and all other Roots that are formed of a thick, fleshy, solid substance. *Radix tuberosa.*

Fibrous Root.] Composed wholly of a number of radicles, or slender fibrous parts, and may be said to be the most common sort of Root, to numerous herbaceous plants in particular, and consists of perpendicular Roots, horizontal Roots, simple Roots, branched Roots; some being very thin and fine like threads, others somewhat fleshy, &c. *Radix fibrosa.*

Creeping Root.] Runs along just under the surface of the earth to a considerable length, emitting at certain distances small fibres below and shoots at top. *Radix repens.*

Globular Root.] Roundish, fleshy, solid Root of the tuberous kind, such as earth-nut, bulbous fumatory, &c. *Radix globosa.*

A grumous or bundled Root.] Composed of many small, oblong, fleshy, kernelly parts, or knobs, all connected at top, and terminated below in radicles or fibres, such as *Ranunculus*, &c. *Radix fasciculata.*

Granulous aggregate Root.] Consists of many small roundish knobs like grains of corn all, clustered together, as in white saxifrage. *Radix granulosa.*

Pendulous clustered Root.] Composed of several fleshy, roundish, knobs, or tubers, suspended, as it were, at the ends of fibres, as in filipendula, peony, potatoe, Jerusalem artichoke, asphodelus, hemerocallis, &c. all of which being of the tuberous-rooted kind. *Radix pendula.*

Handed tuberous Root.] An oblong tuberous Root, dividing and spreading like an open hand, as in handed-orchis. *Radix tuberosa palmata.*

Testiculated Root.] Composed of two roundish tuberous knobs joined in a testiculated manner, as in some sorts of orchis. *Radix testiculata.*

Jointed Root.] Long, thickish, and jointed at certain distances. *Radix articulatus.*

Woody Root.] Becoming of a hard, tough, woody texture, such as the Roots of all trees, shrubs, and under-shrubby plants. *Radix lignosus.*

Tap Root.] Any main Root that runs strait downward in a perpendicular direction, like a carrot, parsnep, &c. and is often applicable to the tree and shrub kind, when the main Root runs directly downright; and in transplanting seedling-trees in the nursery,

&c. it is occasionally recommended to shorten the Tap Root, with a design both to prevent their penetrating too deep into the bad soil, and so force out horizontal or lateral roots, to extend horizontally nearer the surface into the good earth, where they may draw better nourishment. See PLANTING.

As to the duration of Roots, they are either annual, biennial, or perennial, viz.

Annual Roots.—Such that endure but one year at most, then totally perish; as of all those vegetables denominated annual plants. *Radix annuus.*

Biennial Roots.—Continue but two years, then wholly decay. *Radix biennis.*

Perennial Roots.—Being of many years duration, and in some plants both Root and stem subsist for many years, particularly all the tree and shrub kind: many herbaceous vegetables likewise enjoy the same privilege, though the greater part are only perennial in Root, renewing the stalks, &c. annually: however, all herbaceous plants having durable or perennial Roots, are from this circumstance denominated perennials. *Radix perennis.*

Roots, we observed for the general part, penetrate within the ground to seek nourishment from the soil; there are however some exceptions; the mistletoe plant attaching itself to the branches of trees, with its Root uppermost, which penetrates into the bark and wood, drawing moisture for its sustenance. Mosses and some of the fungi likewise attach their Roots to the bark of trees; lichens to stones and rocks, and some aquatics swim both Root and top on the surface of the water.

RAKE, a Garden-Rake for raking ground and raking in seeds, &c.

To suit every department of gardening completely with Rakes, there should be three or four different sizes from about six to eighteen inches long in the head, having handles from six to eight or nine feet in length, and the head toothed with iron teeth two or three inches long, and placed from one to two inches asunder, according to the respective sizes of the Rakes for particular uses, as below.

A large RAKE.—Having the head about twenty inches long, the teeth three inches and half, and placed two inches asunder; being proper for raking stubborn or rough dug ground, and for raking in large kinds of seeds, raking off large weeds after hoeing, and

and for many other purposes in large gardens.

A middle-sized RAKE.—Having the head sixteen inches long, the teeth three inches, and placed one inch and half asunder; being proper for all common raking in ordinary light ground, and for raking in most kinds of small seeds, and many other purposes.

A small RAKE.—Having the head twelve inches long, the teeth two and a half, and placed one inch asunder; proper for fine-raking beds, borders, &c. and raking between certain plants occasionally, where larger rakes cannot be introduced.

A little RAKE.—Having the head eight inches long, the teeth two and a half, and placed one asunder; being very useful for raking between small plants in beds and borders and other small compartments where the plants stand close.

Garden Rakes are made commonly with wooden heads and iron teeth, and have a straight pole for a handle an inch and half thick, and from about six to eight or nine feet long, as aforesaid, having each end of the head hooped with an iron ring to secure it from splitting; and the teeth being generally made flat, the back-edge rounded off to a point, the other straight, and are placed edgewise with the points all inclining moderately inward. But some Garden Rakes have both head and teeth wholly of iron, which, if made neat and light, the teeth well set and firmly fastened, they prove tolerable handy and durable; but as the teeth are rarely set with a proper come, as in the wooden-headed rakes, and being very liable to get loose, I should therefore rather prefer the wooden-headed ones for general service.

Entire wooden Rakes, having the head, teeth, and handle, wholly of wood, are sometimes used for particular purposes, such as raking in some light kinds of kitchen-garden seeds in very light ground, and for raking off large hoed-up weeds in vacant or wide clear spaces, raking up swaths of mowed short grass before the sweepers, also fallen leaves of trees in autumn, and clippings of hedges, &c. and for several other uses.

RAKING. Raking ground is a necessary culture in many cases, to break the surface of the soil small, and render it fine for the reception of particular sorts of small seeds and plants previous to sowing and planting.

Likewise after sowing seeds in the broad-cast way on rough ground, we rake them in to bury them a proper depth for germinating: Raking in seeds is the most expeditious mode of covering them in garden-sowing all kinds of small seeds of hardy plants; the ground being dug, &c. and the surface remaining rough after the spade, the seed is then sowed, and then raked in with an even hand, raking only once or twice in a place, a back and a fore stroke, which being generally sufficient to cover most sorts of seeds effectually; and is the most eligible and expeditious method in the sowing most kinds of esculent or kitchen-garden seeds, and of most kinds of hardy flower seeds, and some sorts of small tree and shrub seeds. See **SOWING SEEDS**.

Raking the ground also among growing plants that stand distant enough to admit the rake, is in many cases of service, particularly where the surface is inclinable to bind, or where numerous small seed-weeds appear, it will loosen the soil and retard the growth of the weeds.

And Raking ground is in many cases necessary for ornament, such as raking smooth the beds, borders, and other compartments of pleasure-grounds, which being now and then repeated gives an air of culture and neatness to the premises.

Likewise after hoeing up weeds Raking them off is eligible in all conspicuous parts of the pleasure ground, in particular where neatness is required, also in other districts where the weeds are like to grow up again or shed their seeds as they lie on the ground.

All Raking should generally be performed in dry weather and when the ground is also moderately dry, for if raked in rainy weather, or when the ground is very moist and cloggy, the surface is apt to cake and bind hard; this should be particularly attended to in sowing seeds, nor will rough digged ground rake well when it is become very dry at top, especially if it was digged wet and suffered to lie till the clods have become dry and hard, in which case it will not rake well until mellowed or pulverised by a shower of rain.

But most of our common light garden-ground generally rakes best when fresh digged, perhaps the same day, or day after at farthest, before dried too much by the sun and wind, or rendered wet by rain, &c.

However Raking should be performed when the ground is in such order as the clods will readily break and fall to bits under the rake without clogging much thereto.

With respect however to Raking ground sowed with seed, particularly in spring and summer it is of importance to sow the seed generally when the ground is fresh turned up, provided it will readily rake without clogging as abovesaid.

RANUNCULUS, Ranunculus and Crow-foot.

This genus comprises a large collection of hardy herbaceous perennials of the grumous and fibrous rooted tribe; some of them most beautiful flowery plants of the gardens, others common weeds of the fields and meadows; the garden kinds having great merit as flower-plants for adorning the flower-garden and pleasure-ground, garnished with divided and entire leaves in different species, and mostly upright branchy flower-stalks, from half a foot to two feet high, terminated by pentapetalous and polyandrous flowers, having double varieties of exceeding beauty.

Class and order, *Polyandria, Polygynia*.

Characters.] CALIX, five oval concave coloured leaves.—COROLLA, five obtuse petals, having small unguis, and a nectarium formed of a small open cavity near the base of each petal.—STAMINA, numerous filaments half the length of the petals, having oblong erect didymous antheræ.—PISTILLUM, numerous germina collected into a head, no styles, but very small reflexed stigmas.—PERICARPIMUM, none, numerous irregular seeds attached to the common receptacle by very short pedicles.

There are near forty different species of this genus, six or eight of which claim general esteem as flowery plants for ornamenting the gardens, and a great number are common weeds in the fields, waters, and pasture ground, not having merit for garden culture: of the garden kinds, the principal sort is the *Asiatic or Turkey and Persian Ranunculus*, which comprise many hundred varieties of large, double, most beautiful flowers of various colours; but several other species having varieties with fine double flowers, make a good appearance in a collection, though as those of each species consist only of one colour, some white others yellow, they are inferior to the *Asiatic Ranunculus*, which being large and diversified a thousand ways in rich colours, in different varieties; how-

ever, all the garden kinds in general, described below, effect a very agreeable diversity in assemblage in the flower compartments, &c. and they being all very hardy succeed in any open beds and borders, &c.

The most noted kinds for garden culture are the following eight species.

RANUNCULUS Asiaticus.

Asiatic, or Turkey and Persian Ranunculus.] Hath a small grumous or bundled root, composed of many small knobbed parts connected at top; crowned with ternate and double-ternate leaves, having trifid-cut lobes; upright flower-stalks branching below, and rising from six to ten or twelve inches high, terminated each by one large flower of many different colours and properties in the varieties; flowering in April, May, and June.

Is a native of Asia, and introduced here long since from Turkey and Persia, and by way of distinction is most commonly called simply *Ranunculus*.

Varieties.] The varieties of this species are amazingly numerous and are divided into two classes, the Old Turkey kind and the Persian kinds, the varieties of the latter amounting to many hundreds and are considerably more various, rich, and beautiful in colour than the others.

Old Turkey kinds.] Rise with a strong generally unbranching stalk a foot high, terminated by one large double flower, sometimes emitting one or two smaller ones from its sides, and of which there are Red flowered,—Scarlet flowered,—yellow flowered—and Scarlet turban flowered, &c.—they being seldom tinged with different colours like the Persian kinds.

Persian varieties.] Rise eight or nine inches high, generally branching from the bottom, producing from five or ten to twenty or thirty flowers on each root, and of which there are Single flowered—Semi-double flowered,—Full-double flowered, being large and full like a double rose, generally filled with petals to the very centre, forming a regular, globular body of admirable elegance, of all sorts of the most beautiful colours in different varieties, and of numerous degrees of deeper and lighter shades, stripes, and tinges in the several colours, so as to cause an astonishing diversity of Reds,—Scarlets,—Crimsons,—Flesh-colours—Purples—Blues,—Violet colours,—Whites,—Cream-colours,—Ash-colours,—Yellows,—Orange-colours,—Lemon-colours,—Golden-yellow,

yellow,—Olive-yellows,—Browns,—Copper-colours,—Blacks,—Black-purples,—Black-violets,—Tawney-colour,—Coffee-colour, &c.—and with flowers of all the above colours variously tinged and striped with two, three, or more different colours, in a very curious manner, forming the numerous varieties, amounting to above a thousand, described in some of the eminent flower-dealers catalogues, varying from one another in some particular in different colours, tints, stripes, and variegations; and a farther encrease of new varieties are annually obtained from seeds, the seedlings generally flower the second or third year, and the select kinds are continued and encreased plentifully by off-sets from the root, every summer after they have done flowering.

All the varieties flower commonly in April and May, but by late planting the roots the blow may be continued till June; and the single and half double flowers are succeeded by abundance of seed; but rarely any from the full doubles: the semi-doubles, however, are greatly preferable to the singles, from which to save the seed for sowing, as there will be a greater chance of having double flowers and seedlings in return.

The roots of all the varieties of this species are of the keeping kind, and being lifted in summer soon after flowering, the off-sets separated and properly dried, they may be kept out of the ground several months; but it is proper to plant a quantity in autumn, and the rest in spring, in order to procure a longer succession of the flowers.

These roots are sold by all the nurserymen and seedsmen in great variety, at from two or three shillings to four or five pounds per hundred and sometimes considerably more, for some very curious varieties.

They are all hardy enough to succeed in any common light garden-earth in open beds or borders, planted some in autumn about September, October, or November, but principally the two latter months, and the rest in February; the fine sorts being commonly deposited in beds by themselves in rows six or eight inches asunder and two or three deep; both to exhibit a grand shew of the numerous varieties all together, and for the convenience of giving occasional shelter from cutting frosts; the early autumnal plantings in particular, that appear above ground in winter or early in spring: though the latter autumnal plantings put in about

November, as they will not come up so early, do not require so much care, and the spring plantings need no protection at all. As to the common or more ordinary kinds they may either be bedded like the others, or distributed about the open borders in little patches of three or four roots in each, in assemblage with other border flowers. See their *General Culture*.

²RANUNCULUS *aconitifolius*.

Aconite-leaved White-mountain Crow-foot, or Fair-maid of France.] Hath a strong fibrous perennial root joined in a head, crowned with large quinate, or five-lobed leaves, all the lobes spear-shaped, cut, and serrated; upright, strong, flower-stalks, a foot and half or two feet high, divided into many branches, garnished with small leaves like the lower ones, and all the branches terminated by pure white flowers, appearing the end of May and beginning of June.

Varieties.] Common single-flowered,—Larger double-flowered, very beautiful, and worthy of a place in every garden.

³RANUNCULUS *Acris*.

Upright Meadow Ranunculus, or Yellow, Crow foot.] Hath a fibrous clustered root, joining in a head, crowned by tripartite-multifid, or much divided leaves; upright flower-stalks a foot high, branching at top, having the upper-leaves cut into many narrow segments, and all the branches terminated by a bright yellow flower, appearing in May.

Varieties] Common single-flowered of the pastures,—Double-flowered of the gardens,—Proliferous double flowered, one flower growing out of the middle of another. The double kinds only are proper for garden-culture.

This species in its single state is found in abundance in every pasture ground, and is seldom admitted into gardens; but the double varieties are very pretty, and merit a place in every good collection of perennials.

⁴RANUNCULUS *repens*.

Creeping, or running Yellow Crow-foot.] Hath fibrous, perennial roots, crowned with compound leaves, trailing, creeping, shoots, rooting as they run along, and furrowed pedunculi terminated by bright yellow flowers, having spreading cups; flowering in May and June.

Variety.] Common single-flowered of the meadows and pastures,—Double flowered of the gardens.

⁵RANUNCULUS *Ficaria*.

Ficaria, Fig-wort, or Pile-wort.] Hath a grumous or bundled tuberous root, heart-shaped, angular, smooth leaves, on strong foot-stalks, and upright simple stalks four or five inches high, terminated by large shining yellow flowers, in March and April.

Varieties.] Common single-flowered of the meadows, &c.—Double-flowered of the gardens.

⁶RANUNCULUS *Amplexicaulis*.

Amplexicaulous, Plantain-leaved, Alpine Ranunculus.] Hath a bundled perennial root, oval, acuminate leaves embracing the stalk, the stalk rising from six to eighteen inches high, branching and terminated by several single white flowers; appears in April.

⁷RANUNCULUS *Gramineus*.

Gramous or Grass-leaved Pyrenean Ranunculus.] Hath a bulbous perennial root, spear-shaped, narrow, grassy, sessile leaves; upright stalks about a foot high, branching upwards, each branch terminated by a small, pale, yellow flower; appearing in May.

Varieties.] Common single-flowered, — Double-flowered.

⁸RANUNCULUS *Grandiflorus*.

Great Yellow-flowered Oriental Ranunculus.] Hath a fibrous perennial root, multifid or many-parted leaves; erect stalks a foot or more high, garnished with two alternate close-sitting leaves; and terminated by one large yellow flower; appearing in May.

The flowers of all the above eight species of *Ranunculi* in their single or characteristic state, consist each of five obtuse bright petals, and the middle filled with numerous stamina, &c. succeeded by abundance of seed; but in the double-flowered varieties the petals are multiplied in many series, which in the full doubles are continued to the very centre, like a double-rose, in which consists their excellence as garden-flowers for ornament: though in these very luxuriant or full double-flowers, the multiplicity of petals often supplant all the stamina that no seed is produced. This however is amply compensated by the singles and half-doubles, which are succeeded by great plenty of seed, ripening in June and July; but it is only of the *Asiatic Ranunculus* that seed is required, which in this species in particular is always productive of a great variety of new sorts, but not in any of the other species, remarking, that

the finest semi-doubles are the sorts from which to save the seed for propagation.

All the species are perennial in root, and annual in leaf and stalk, which rise in spring and decay in summer and autumn soon after they have flowered; the roots of all the sorts being abiding, encrease abundantly by off-sets every year for propagating the particular varieties.

Considered as garden-flowers, all the sorts demand attention, the Asiatic kinds however stand foremost considerably in point of beauty, elegance, and variety, but some of all the sorts are proper furniture for the borders and other compartments of the pleasure-garden, where being disposed in assemblage they will effect a good diversity in flower for two or three months, and some of the finest of the Asiatic varieties should also be deposited in beds by themselves, as before observed, in order to exhibit a grand blow together; observing that the roots of the fine varieties of this species should be lifted every year after blowing to separate the off-sets and fresh prepare the mould, &c. but all the other fibrous-rooted species being distributed about the borders may remain undisturbed two or three years, or as it shall seem necessary according as they may want trimming to keep them within bounds, or to have the roots taken up occasionally to part them for propagation.

Culture of the Asiatic Kinds.

The *Asiatic Ranunculus* in particular is in high estimation among the florists, and is deservedly an object of admiration on account of the great number of the varieties and the beauties the flowers possess, in their elegance of form and vast variety and richness of colour render them superior to most other flowers of the season, and highly merit culture in every garden.

This species in all its varieties will succeed in any light, rich, garden earth; but the florists often prepare a particular compost for the fine varieties, consisting of good garden mould or pasture-earth, sward and all, a fourth-part of rotted cow-dung, and the like portion of sea-sand; (see COMPOST;) and with this they prepare beds four feet wide and two deep: however in default of such compost, use beds of any good light earth of your garden; or if necessary it may be made light and rich with a portion of drift-

drift-sand and rotten dung, cow-dung is most commonly recommended; but they will also thrive in beds of well wrought kitchen-garden earth, and they often prosper well in the common flower borders.

The season for planting the roots is both in autumn and spring; the autumn plantings generally flower strongest and soonest by a month at least, and are succeeded by the spring planting in May and June. Perform the autumnal planting in October and early part of November, but some plant towards the latter end of September in order to have a very early bloom; but those planted in that month and beginning of October often come up with rank leaves soon after, in winter, so as to require protection in hard frosts; those however planted about the middle or latter end of October and beginning of November rarely shoot up strong till towards spring and will not require so much care of covering during winter; and the spring planting may be performed the end of January or beginning of February, or as soon as the weather is settled; they will not require any trouble of covering, and will succeed the autumnal plants regularly in bloom, and will flower in good perfection. Thus by two or three different plantings you may obtain a succession of these beautiful flowers in constant bloom from April till the middle of June; but the autumnal plants for the general part not only flower strongest, but the roots encrease more in size, and furnish the best off-sets for propagation: it is however proper to plant both in spring and autumn.

Prepare for the choicer sorts four-foot beds of light earth, as aforesaid, by good digging, breaking the earth fine, but not sift any part thereof, laying them of a rounding form, and rake the surface smooth, then plant the roots in rows lengthwise the beds, either by drilling them in two inches deep and six inches distance in the row, and the rows six or eight asunder, or may plant them by bedding-in or by dibble-planting the same depth and distance. See PLANTING.

Those designed for the borders should be planted generally towards the spring in little clumps or patches, three, four, or five roots in each, putting them in either with a dibble or trowel two or three inches deep, and three or four asunder in each patch, and the patches from about three to five or ten feet distance, placing them rather forward in the border.

As to their general culture after planting, observe in winter, that such of the forward

autumnal-planted roots of the choice sorts in beds as have shot above ground, should have occasional shelter from hard frosts by mats supported on low hoop-arches; or in very severe weather may cover them close with dry long litter, but remove all covering in open weather: and in the spring when the flower-buds begin first to advance, it will be of much advantage to shelter them in frosty nights with supported mats, suffering them however to be open to the full air every day; but the latter plantings that do not come up in winter or very early in spring whilst frosty nights prevail, will not require any protection, and all those distributed in patches about the borders must also take their chance in all weathers; those of the different seasons of planting will succeed one another in flowering from the beginning of April until the middle of June, though the May blow generally shews to the greatest perfection.

After the blow is past and the leaves and stalks withered, take up the roots, and dry them in the shade, then clear them from all off-sets and adhering mould, and put them up in bags or boxes till next planting seasons, when they must be planted again as before directed.

But in each season of planting, it is highly necessary to plant them either in entire new beds, or the old refreshed with some fresh rich earth or compost, working the old and new well together, this being necessary in order to invigorate the growth of the plants.

Their Propagation.

All the varieties of the *Asiatic Ranunculus* propagate abundantly by off-sets from the root, and new varieties are gained by seed.

By off-sets.—The time for separating the off-sets is in summer when the flower is past, and the leaves and stalks are withered, then taking up all the roots in dry weather, separate the off-sets from each main root, and after drying the whole gradually in some shady airy room, put them up in bags in the dry till the autumn and spring seasons of planting, then plant them as before, placing all the off-sets in separate beds, many of them will blow the first year, but in the second they will all flower in good perfection.

By seed.—Save a quantity of seed from the finest semi-double flowers, and sow it either in August or in March or April, though

to save trouble of winter covering some prefer the spring; it should be sowed in light rich mould, either in pots or in an east border, drawing very shallow flat drills five or six inches asunder, in which sow the seeds thinly, and cover them lightly with earth, giving frequent refreshments of water in dry weather, and in a month or six weeks the plants will rise with small leaves; observing to continue the light waterings in dry weather to preserve the soil moist during their summer's growth to encrease the size of the roots; and in June when the leaves decay, take up the roots and preserve them till the season for planting, then plant them in common beds, as before directed, and they will flower the spring following, when all the doubles of good properties should be marked, and the singles thrown away.

Culture of the other seven Sorts.

All the other seven species of *Ranunculi* succeed in any common soil and situation, so may be dispersed about the different flower compartments, where they may constantly remain, only trimming them occasionally once in a year or two, or when they have encreased into large bunches they may be taken up in autumn or spring to divide them for farther encrease, and replant them again directly.

Their propagation is very easy, for they multiply exceedingly by the roots.

So that when intended to propagate them the roots may be slipped or parted in autumn when past flowering, or in the spring before they begin to shoot, and the slips may either be planted at once where they are to remain, or in nursery rows for a season, then planted out finally.

RAPHANUS, Radish.

The plants are herbaceous, annual, esculents of the kitchen-garden, valuable for their eatable roots for spring and summer service, having fusiforme and globose roots in different varieties, broad rough leaves, and cruciforme flowers.

Class and order, *Tetradynamia Siliquosa*.

Characters.] *CALIX*, four oblong, erect, deciduous leaves, — *COROLLA*, four heart-shaped, spreading, cruciforme petals, and four melliferous, glands, — *STAMINA*, four long and two short filaments, having simple antheræ, — *PISTILLUM*, an oblong ventricose germen, scarcely any style, crowned by a capitated stigma, — *PERICAR-*

PIUM, an oblong, gibbous, or swelling, smooth, bilocular pod, filled with roundish seeds.

This genus retains three species, one of which only, *Common Radish*, is for our purpose; observing, the botanists admit but of one species of this sort, all the different sorts of the taper-rooted and round Radish, both red, purple, white, and black sorts, are supposed varieties only of the same species; and, indeed, we may often observe here and there some of all the varieties degenerate both in shape and colour; however by care in saving the seeds of the different sorts separate and distant from one another, the different varieties are continued distinct.

The species is,

Raphanus Sativus.

Cultivated or common Garden Radish.] Hath taper and round fleshy roots, crowned by broad, rough leaves; and when they shoot for seed, send forth upright, strong, widely, branching stalks, a yard or more high, having all the branches terminated by whitish cruciforme, light purplish flowers, succeeded by taper swelling pods with two cells.

The botanic distinction is, — *Raphanus* with taper, swelling, bilocular pods.

Varieties.] All the varieties, though many of them appear as distinct species by the shape and colour of the root, yet as they all bear exactly the above specific distinction in the seed-pod, they are considered all as varieties only of one another, belonging all to the species *Raphanus Sativus*, and the principal sorts are the following, which may be divided into two classes, — Common taper-rooted Radishes, — and Turnep rooted kinds.

Common Taper-rooted Kinds.

Short-topped Radish. — Having an oblong taper, reddish purple root, some deep, others pale-coloured, crowned with only a small short top of leaves, which is a particular merit peculiar to this sort, as the plants require both less room to grow, and the root swells faster in proportion, attaining perfection much sooner than the large-topped kinds, being also a firm, crisp, tender-eating Radish, so is preferable for general culture, both for all early crops in frames and borders, and for the general crops in the open quarters; the pale-rooted sort is generally milder to eat than the deep red or purple kind.

This

This may be sowed at different times, from October or November until May; but from January till March and April is the general sowing season, at two or three weeks intervals, for the main crops.

Salmon-coloured Radish.] Having a fine long, taper, pale-scarlet root, crowned generally with a pretty large top of leaves, but if allowed room, the root swells freely to a handsome size, and is a firm, crisp, excellent Radish for the later crops, sowed in March, April, and May, in open situations.

Variety.] Short-topped early Salmon Radish.

Long-topped Red Radish.] Having an oblong, taper, red root, crowned with a large top of leaves;—not proper for general culture.

Deep-red Radish.] Having an oblong, taper, deep-red root, apt to become soon hot and sticky; not proper for general culture.

Sallad Radish.] Any sort of Radish may be used as such, being sowed thick like cresses, and mustard, to gather whilst young in the seed leaf, to mix in sallads; but seed of any of the common long-topped sorts may be sowed for this purpose. See SALLAD HERBS.

Turnep-rooted Kinds.

Small White Turnep-rooted Italian Radish] Having a small, round, turnep shaped, white root, being very like young Dutch turneps; and it used whilst quite young, they eat very crisp, mild, and well tasted, and make an agreeable variety at table; are in highest perfection in April and May, or in autumn: sow them in February, March, and April, for spring use; and end of July or beginning of August, for autumn eating.

This sort is often brought to the London markets in the spring, about April and beginning of May, generally in bunches, and are often mistaken for young turneps.

Large, white, Turnep-rooted Spanish Radish] Having a moderately-large, round, orbicular, turnep-shaped, white root, esteemed chiefly for autumn eating, and early part of winter; sowing them in July and beginning of August.

Black Turnep-rooted Spanish Radish.] Hath a large, roundish oblong, black coated root, but white within, greatly esteemed by many for autumn and winter eating, either alone or sliced in sallads: sow them in open ground in July and beginning of August, they will come in for use in September and

October, and continue in perfection all winter.

All these varieties of *Raphanus Sativus* are annual plants, which being sowed in the spring attain perfection in two or three months, and shoot up soon after into stalk for flower and seed, which, ripening in autumn, the whole plant, root, and top perishes; so that a fresh supply must be raised annually from seed in the spring, performing the sowings at several different times, from about Christmas until May, in order to continue a regular succession of young tender Radishes throughout the season; allowing only a fortnight or three weeks interval between the sowings, for one crop will not continue good longer than that space of time, before they will either run to seed, or become tough, sticky, and hot to eat.

They are all tolerably hardy, except very early raised plants in their infant state, which are liable to suffer by frost; and they all succeed in any common garden earth, and almost any situation and exposure open to the sun and free air; though for the early crops a warm south border, or other sheltered sunny situation, is proper, both to bring the crop forward, and for protecting the plants from cold, as being impatient of frost whilst young, as above said; therefore when they rise early it is proper to cover them in frosty nights with straw or mats; but the main crops sowed in February and March, &c. may be in any open situation, as they want no protection.

Culture of the common Spindle-rooted Radish.

To have Radishes as early as possible, they are sowed both on warm borders and in hot-beds, under frames and lights.

But first of their culture in the open ground. To have early Radishes in warm borders, you may begin sowing a few short-topped Radish in October, November, and December, but not any general early sowing till about Christmas, or early in January, if the weather is open; or in cold wet grounds not till the end of that month or beginning of February; for the very forward sowings performed before the middle or end of December, are not to be depended on, though such of them as survive the winter's frost, will be fit to draw sometimes in January and February; they however will be hard and sticky; but as they may be deemed a great rarity at a very early season, and as the seed is cheap enough, and

a small space of ground will be sufficient, it may be worth the trial to sow some in the middle or end of October, and a few more in November and December, and let them take their chance of the winter; and if they should fail, the same ground will do to sow again time enough for a good spring crop. However, for the general early crop, the end of December, or the beginning or middle of January, according to the temperature of the season, is time enough to begin, when, if open weather, it is proper to think of sowing a good crop in a warm dry border, or any warm-lying light ground; and about the end of January, or beginning of February, sow a more general crop.

Let the ground for the reception of the seed be trenched one good spade deep at least; or it will be of advantage, if it has been previously trenched up in ridges, then levelled down, the clods well broken, and the surface laid even.

Then being provided with some good short-topped Radish-seed, and with which, if you think proper, you may mix a sprinkling of coss-lettuce and carrots, they will come in for use after the Radishes, and be some weeks earlier than the main crops. Sow the whole together broad-cast all over the surface tolerably thick in the early sowings, and rake them well in with a large rake; or, if in a large open plat of ground, or where the ground is rather wetish or stiff, it is proper, for the early sowings in particular, to divide it into four or five-feet wide beds, with foot and a half wide alleys between; then sowing the seed, strike it a little in with the teeth of the rake, and then cast some earth of the alleys over them half an inch deep, and rake it smooth.

The London kitchen gardeners, after performing the main early sowings from about Christmas till the beginning of February, generally cover the ground directly with clean wheat straw, about two inches thick, both to keep the surface warm, and keep off birds from the seed, suffering it to remain till the plants are fairly come up, as it contributes to their more early rising, and is then raked off lightly every mild day.

However, covering these early crops is very eligible, when the plants come up, every frosty night; for this purpose have either a quantity of dry wheat-straw, or dried fern, &c. laying it ready in the alleys, and every night, when there is an appearance of frost,

throw it over the plants with a pitchfork, two inches thick or more, if the weather should prove severe, and rake it off lightly every mild morning with a wooden rake; but in severe weather must remain night and day: and this covering, if carefully spread on and taken off, will no ways bruise the plants, but will not only protect them from the frost, but continue them greatly forward in their growth. But instead of straw some use large garden-mats, especially after the plants are up, and a little advanced, generally sticking two or three rows of stout wooden pegs along the border or beds, in a slanting manner, two or three inches above ground, to support the mats from the plants, or where there is only a small quantity, you may arch the beds with hoops for the support of the mats.

The above work of covering early Radishes, may to some appear tedious and troublesome, but it is soon done when every thing is laid ready, and is universally practised by the London gardeners, to large tracts of ground, continuing it till the plants are fairly in the rough leaf, and firmly rooted; for the early quite young plants, being not only liable to be greatly cut at top by the frost, but even those exposed thereto and seemingly survive, are often started at the root; that is, the frost heaving the ground, it draws the plants up along with it, and breaks the tender radicle or lower perpendicular fibre, which not only retards their growth till they form new fibres, but the terminal downright fibre being broken off, prevents their shooting in length, that they can never form handsome Radishes, but become what the market gardeners call chumps: so those gardeners who raise large quantities for the supply of the London markets, find their account in allowing the early main crops occasional protection, which by insuring fuller crops coming in earlier and in greater perfection, always pay them sufficiently for the trouble of covering.

When the Radishes however are a little advanced in growth, being in the rough leaf, it is proper to thin them, where they stand too thick, to two inches distance, which, as you will begin drawing them for use when quite young, may be room enough at present, as the daily thinning for the table or market will give them more and more room every day.

In very dry weather, in March and April, it is adviseable to give them a good watering every evening or morning, which will both
forward

ward their growth considerably, increase the size of the root, and render them more crisp and mild to eat.

Continue repeating the sowings every fortnight or three weeks, till March, then sow every fortnight until the end of April; or where a long succession of young Radishes is required, the sowings may be continued all May, or even during the summer, until the middle or end of August, if required; those sowed in July and August will be very fine in September and October; observing in sowing the latter crops of Radishes, from the middle of February during the rest of the sowing season, they may be sowed in any open ground, and want no covering in any weather; and in the main crops of Radishes, if necessary to make the most of your ground, you may mix a sprinkling of coss-lettuce and round-leaved spinach seed, sowing the whole together broad-cast, and rake them in evenly with a large rake as aforesaid; the three crops will be coming forward all at the same time, without interruption to one another; the Radishes come in first, then, after these are drawn off, the spinach flourishes, and soon becomes fit for use, which is succeeded by the lettuce; and between these may sow pickling cucumbers or kidney beans, &c. in the beginning of June.

But in sowing the main general crops of Radishes in the open quarters, the market gardeners generally sow them on the same ground where they plant out their main crops of cauliflowers and cabbages, mixing spinach with the Radish seed, as above said, sowing the seeds first, and rake them in, then plant the cauliflowers or cabbages; the Radishes and spinach come in for use before the other plants begin to spread much, and as soon as those small crops are all cleared off for use, then hoe the ground all over to kill weeds and loosen the soil, and draw earth about the stems of the cauliflowers and cabbages.

With regard to the culture of these general crops of Radishes, they require very little, which is occasional thinning where they are too thick, performing this when the plants are come into the rough leaf, either by hoe or drawing them out by hand; though for large quantities, small-hoeing is the most expeditious mode of thinning, as well as prove very beneficial to the crop by loosening the ground; however, in either method thin the plants to about three inches distance,

clearing out the weakest, and leave the strongest to form the crop.

Early crops in hot-beds, &c. — When it is required to have young Radishes as early in the spring as possible, they may be greatly forwarded by aid of hot-beds under frames and glasses, or other shelters.

This work may be begun any time in winter, if thought proper; but from Christmas till Candlemas is the most eligible season to ensure a thriving crop. Make a hot-bed for one or more three-light frames, about eighteen inches depth of dung, which is sufficient, as the heat is only intended just to bring up the plants, and set them a-going a little at first; put on the frame directly, and earth the bed six or seven inches deep with light rich mould; then having the true short-topped Radish-seed, sow it on the surface of the bed moderately thick, and cover it evenly half an inch thick with light mould, and put on the lights, and the plants will come up in a week, or probably in less time, if there is a tolerable warmth in the bed; observing, when they appear, to admit air every day, either by tilting the lights considerably in the front or behind, according to the temperature of the weather, or in fine mild days take them quite off; for a large portion of fresh air is necessary every day, otherwise the plants will draw up to shank, and go off; remarking, that after the plants have had a week or fortnight's growth, they should be thinned where they have risen too thick, leaving them about an inch and a half apart; then observing, if the plants have unavoidably drawn up with long shanks, it is adviseable to sift some light mould out of a fine sieve in amongst them evenly all over the bed, so as to mould their shanks about half an inch or an inch, or more thick, as there shall be occasion: this will greatly strengthen their growth, and promote the goodness of the roots; still remembering to indulge them with a large portion of fresh air every mild day, and cover them on nights; thus the plants will advance fast to perfection, and be fit to draw in six weeks.

But in want of frames and glasses for the above purpose, you may cover occasionally with mats, making the hot-bed as before, and mould it the same depth, securing the sides of the mould with boards or wreaths of straw-bands; then cradle or arch it over with hoops or rods for the support of the

mats, which must be used every night and all bad weather, till the plants are ready for use.

Or in case of scarcity of dung for making hot-beds as above, you may sow some seed in beds of common earth under garden frames, and put on the lights every night and all bad weather; and thus you may raise the plants for use sooner by a fortnight than in the common open borders.

Culture of the Turnep-rooted Kinds.

As to the turnep-rooted Radishes, they should always be sowed in some open situation and light ground.

The small round sort may be sowed in spring, in February, March, or beginning of April; or for autumn use, sow them in July and beginning or middle of August: at either season sow them broad-cast thinly, and rake them in evenly, and when the plants come up and get into the rough leaf, they must be thinned either by hoe or hand, setting them out four or five inches asunder.

The other two large turnep-rooted kinds should be sowed principally in autumn, about the middle or end of July, in any open situation thinly, and raked in; and when the plants have got rough leaves about an inch broad, hoe them out to six or eight inches distance, they will attain full growth for use in September and October, and continue good great part of winter, particularly the black sort; however, it is proper to take up a quantity in November or December, before attacked by severe frosty weather, and depositing them in any sheltered place in sand, they may be kept in good perfection till the spring.

Saving Seed of all the Sorts.

To save Radish seed, you may either leave some plants of the first main crops to run up, or transplant a quantity into an open spot of ground; the latter is more particularly to be recommended for general practice, because, by drawing up the roots for planting, you can judge of the goodness in respect to shape and colour; they should be planted in an open situation.

The proper season therefore for planting out Radishes for seed is the beginning or towards the middle of May, just when the roots are in their prime, chusing showery weather if possible.

Observe of the common taper-rooted Radishes to select them with the shortest tops,

and the longest straight roots of the best colours in the respective varieties, remarking particularly of the short-topped kind, to chuse them always with the very smallest tops, and as of this sort there being some with roots of a deep reddish-purple colour, and others having pale-coloured clear roots, the latter of which are generally more crisp and mild than the former, and are particularly esteemed about London; so that in drawing them to plant for seed, you should keep them separate, observing also the same of the other varieties: then having previously digged an open space of ground for their reception, plant the Radishes, with their leaves entire, by a dibble, in rows two feet and a half asunder, and the same distance in the lines, placing them in the quincunx order, and each root down to its leaves, directly giving them a good watering, to settle the earth close about the roots, and forward their striking, repeating the waterings in dry weather till they have taken fresh root, and shew signs of growth.

As to the turnep-rooted kinds, some should be sowed in the spring, about March, purposely for seed, and may either remain where sowed, hoeing them out to wide distances, or when the roots are arrived to perfection in May or beginning of June, a quantity may be transplanted, choosing the roundest, best-shaped, fairest root, and planted in rows two feet and a half asunder, as before observed, and water them.

Observe however if any of the large turnep-rooted kinds of the autumn crops should stand the winter, some may be left, or planted out for seed in February.

All the sorts will soon take root, and shoot up to stalk in June, branch widely every way, flower in July, and the seed will ripen in September.

Their ripening is discovered by the pods and seeds changing brown; then cut up the stalks, and spread them in the sun a week or two to dry and harden the pods and seeds, and then thresh them out; observing the seed-pods being of a tough nature, they do not readily break to discharge the seed, so that sometimes they require to be exposed to the weather some considerable time, to render the husks brittle, and sometimes they require to be threshed two or three times over; when they however are threshed out, clean the seed from the rubbish, and put it up in bags out of the way of mice.

REED HEDGES.

Reed Hedges are temporary internal fences made with dried Reeds, which may be had cheap enough all over the kingdom, and may be expeditiously formed into Hedges by the assistance of posts and railing, and make a cheap temporary fence of great utility for occasional use in gardens, to inclose particular internal spaces of ground, to afford shelter to certain seedling plants, both in nurseries and large kitchen gardens.

But Reed Hedges are particularly useful in nurseries, to form places of shelter for many sorts of seedling trees and shrubs, &c. which being tender whilst young, require the shelter of a fence in winter to break off the keen edge of cutting blasts two or three years, till they gradually gather strength and a greater degree of hardiness; these kind of fences are also useful in nurseries for training several sorts of wall fruit-trees against, to form them for walls in gardens, being what the nurserymen call *Trained Trees*; so that these Reed fences being cheap and soon formed, are often used in the nurseries for a double purpose, that is, serving both for shelter, and affording an opportunity of planting trees against each side eight or ten feet asunder, for the purpose of training for walls as aforesaid. See NURSERY, &c.

Likewise in large open kitchen gardens Reed Hedges are often employed to good advantage for sheltering tender plants and early crops: such as inclosing particular spaces for a melonary, or place wherein to raise early melons and cucumbers, and often as cross internal fences, running across the ground at considerable distances, under which forming warm borders for the purpose of raising various early crops of esculents more plentifully; serving also to break the force of cutting and tempestuous winds from the crops in the adjacent quarters, and for which purposes many of the kitchen-gardeners about London use these kind of Hedges.

Remark however, these Reed Hedges are not at all adapted for outward fences, as they may be very easily broke through.

But as internal fences for sheltering plants, they are accounted better than walls or pales, because the Reeds generally deaden the winds without reverberating them back again.

The proper Reeds for making these fences are the dried stems of the *Arundo Phragmitis*, or Common Marsh Reed, which, growing in great abundance by river sides, lakes, and

marshy places all over the kingdom, furnish a crop of stems annually fit to cut in autumn, and being then bound in bundles, are stacked up or housed to remain for use; and great quantities are annually brought to London by water, and deposited in warehouses near the river, where they have great demand for them among the gardeners for making Reed fences.

As to the method of making these fences, they are sometimes erected in fixed ranges, and sometimes formed into moveable pannels. When to be formed into fixed fences, arrange some stout posts six or eight feet asunder, and five or six high, and from post to post carry two or three ranges of flat thin railing, one range near the bottom, another near the top, and a third in the middle; against this railing place the reeds two or three inches thick, having other railing fixed directly opposite, so that the Reeds being placed all along between the double railing, the bottoms resting either upon a plate of wood, or let into the ground, as may be convenient; and as soon as one pannel is placed, nail the railing as close as possible, and either drive some long spike nails through each double railing, or bind them with strong withy bands, but nailing is the best, in order to bring them as close as may be, to secure the Reeds firmly in the proper position; and thus proceed till you have completed the range of fencing.

But when intended to have any of these fences formed into moveable pannels, to remove to different places occasionally, a framework of railing is prepared as above, each pannel six or eight feet long, and the Reeds fixed therein as before directed; then where-soever it is intended to place them, posts must be ranged six or eight feet distance, to support the several pannels.

RESEDA, Bastard Rocket, *Mignonette*, &c.

It consists principally of herbaceous annuals, biennials, and perennials; some of the biennials in particular merit culture, one as an odoriferous garden plant, another for field culture, for the use of the dyers, &c. growing from one to three feet high, having oblong and lanceolate leaves, and terminated by spikes of small unequal flowers.

Class and order, *Dodecandria Trigynia*.

Characters.] CALIX, is monophyllous, many-parted, and permanent. COROLLA, several small, unequal, generally trifid petals, the upper being gibbous at the base, contain-

containing a honey juice, and a glandular, plane, erect nectarium at the upper side of the receptacle, between the stamina and upper petal, connivent with the base thereof. STAMINA, twelve or fifteen short filaments, having obtuse erect antheræ. PISTILLUM, a gibbous germen, three or more very short styles, having simple stigmas. PERICARPUM, a gibbous, angular, unilocular capsule, with apertures between the styles, having many kidney-shaped seeds adhering to the angles of the capsule.

There are many species, the most noted of which, for our purpose, are the two following, the first for the pleasure-ground, the other for field culture.

RESEDA Odorata—(biennial and tender.)

Odoriferous Reseda, commonly called Mignionette.] Hath a tough fibrous root, sending forth several weak branchy stalks, growing twelve or eighteen inches long, having oblong, entire, and trilobate leaves, and all the branches terminated by long spikes of greenish-white sweet-scented flowers, having the calix equal with the petals.

This plant is biennial, is in high estimation for its agreeable fragrance, though is not ornamental neither in its growth nor flowers, but the latter impart a most delightful odour widely around, flowering in summer, continuing several months, even all winter, if sheltered in a green-house, &c.

Is a native of Egypt; succeeds here in the open air in summer, but requires shelter in winter.

RESEDA Luteola—(biennial and hardy.)

Luteola, or Yellow Herb, commonly called Weld, Wild Woad, or Dyer's Weed.] Hath tough fibrous roots, crowned with long, narrow, spear-shaped, entire leaves, spreading on the ground, upright stems a yard high, garnished also with spear-shaped narrow leaves, and terminated by long loose spikes of yellow flowers, having quadrifid cups; grows wild on old walls and the sides of banks and sterile places in England, &c. but is cultivated in fields for its flower-stems, for the use of the dyers.

Both these species are biennial plants, the first is somewhat tender, requiring shelter from frost; but the second is very hardy; observe however the first sort may be deemed annual as well as biennial, for being sowed early in spring, will flower and perfect seeds the same year, and totally perish in winter, if not sheltered; but being sheltered

all winter in a green-house, they will continue till next summer: the second sort however is perfectly biennial; for being sowed one year, it does not run up to stalk till next summer, when it flowers and ripens seed, and wholly decays soon after.

Method of Propagation.

They are both raised from seed sowed annually, the first sort principally in a hot-bed, the other in the open ground.

The *Odoriferous Reseda*, or *Mignionette*, should be sown in March or April, in any moderate hot-bed, as directed for tender annuals, sowing some in small pots to remain, and some for transplantation into the full ground, in the end of May or June; however, whilst they remain in the hot-bed, indulge them with fresh air daily, and occasional waterings in common with the other plants; and if some were pricked upon a fresh hot-bed, or into small pots, three plants in each, and plunged in the hot bed, it will forward them considerably: in the end of May or in June, according to the strength of the plants and temperature of the season, taking opportunity of mild moist weather, remove them into the full air, retaining some in pots, others transplant with balls into the borders, observing, when the stalks of the plants advance, to place short sticks for their support, and to which tie the stems in a neat manner.

But the seed of this plant will also grow in the full ground, sowed in the middle of April and in May, when the season is become warm and settled, sowing them in light earth, either in a bed by themselves, and raked in lightly, or in patches about the flower-borders, covering them a quarter of an inch deep; and in either method suffer the plants to remain where raised, giving occasional waterings.

And if some plants are raised in pots in May, or any time in summer, or towards autumn, and the pots plunged in an east border, or where they may have only the morning sun, well watered all summer, and in October placed in a green-house, they will stand the winter, and some of them raised forward in the summer, will flower all the winter season, others raised towards autumn, will continue increasing in growth, and flower strong early next spring and summer.

They ripen seeds in September, when they should be carefully gathered in dry weather.

The

The culture of the Weld, or Wild Woad, is generally in large quantities in fields, and thrives in any poor land, though it will consequently be more prosperous in a rich soil; the beginning of August is the best season for sowing it, allowing about one gallon to an acre, and sow it broad cast evenly, and harrow it in; the plants will soon come up the same season, and when they are a little advanced in growth, hoe them to thin the crop and kill weeds, leaving the plants six inches asunder; they will shoot up into stalk next spring, and flower in June, at which time the plants should be pulled for use, laid to dry, then tied in bundles and housed.

A quantity of the plants should be suffered to stand every year for seed.

RHAMNUS, (*Cerva spina*) Buckthorn.

The plants are of the tree and shrub kind, comprising several deciduous and evergreen species for adorning the pleasure-ground and green-house collection, garnished with oval and oblong leaves, and small infundibuliforme flowers mostly in bunches, succeeded by small round berries.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, none. COROLLA, is monopetalous, funnel shaped, four or five-parted, and spreading, having a small scale at the base of each division. STAMINA, five, or generally as many filaments as there are divisions in the corolla, inserted under the squamulae or scale of the petal, and terminated by small antherae. PISTILLUM, a roundish germen, filiforme style, crowned by an obtuse stigma, and divided into fewer segments than the corolla. PERICARPIUM, a round naked berry of three or four cells, having the like number of roundish hard seeds.

Late improvements in botany have ranged several genera of former authors as species only of this genus, such as the *Frangula*, or Berry-bearing Alder,—*Paliurus*, or Christ's Thorn,—*A. aternus*,—and *Zizyphus*, or Jub tree; all of which bearing the characters exactly of *Rhamnus*, are to be now considered as species of that genus.

They consist of deciduous and evergreen kinds, mostly of hardy growth, and some of tender quality.

Hardy deciduous Kinds.

Under this head is comprised the common Buckthorn, *Frangula*, and *Paliurus*.

¹RHAMNUS *Catharticus*.

Cathartic, or Common Purging Buckthorn.] Grows twelve or fourteen feet high, branching numerous and irregularly, smooth, and armed with sharp spines, oval, spear-shaped, sawed, smallish leaves, on long foot-stalks, and at the sides of the branches clusters of small, quadrifid, dioecious, greenish flowers, succeeded by black berries in autumn, having four seeds.

Varieties.] Dwarf Buckthorn, growing about a yard high.—Dwarf long-leaved Buckthorn, growing five or six feet high.

The common sort grows wild in hedges in many parts of England, but is admitted for variety in the shrubbery plantations; the berries of it are used in medicine, being made into a syrup, good for many disorders, given as a cathartic or purge, said to be good to purge watery humours, and against the dropsy, jaundice, itch, and all eruptions of the skin, &c.

²RHAMNUS *Frangula*.

Frangula, or Common Berry-bearing Alder.] Rises with a woody stem, branching numerously ten or twelve feet high, without thorns; oval-spear-shaped, entire leaves, two inches long; and small, monogynious, hermaphrodite, greenish flowers, terminating the shoots in clusters, succeeded by round berries, ripening to a black colour in autumn, having generally but two or three seeds.

Varieties.] Dwarf Berry-bearing Alder, growing two or three feet high—Dwarf long-leaved.

The common sort is an inhabitant of our woods in many parts of England, but has been long admitted in garden plantations, to increase the variety of hardy deciduous shrubs.

³RHAMNUS *Alpinus*.

Alpine rough-leaved Berry-bearing Alder.] Rises with a woody stem, branching numerously twelve or fourteen feet high, without thorns; larger oval-spear-shaped rough leaves, doubly crenated; and dioecious flowers.

Variety.] Smooth-leaved Alpine *Frangula*.

⁴RHAMNUS *Paliurus*, (*Spina Christi*).

Paliurus, or Christ's Thorn.] Rises with a shrubby stem, branching ten or twelve feet high, having numerous weak pliant branches, armed with sharp thorns by pairs, at every joint, having the lower one reflexed; oval leaves alternately, near an inch long, and trigynous yellowish flowers in clusters at the axillas of the branches, succeeded by small, roundish,

roundish, compressed berries, surrounded by a membranous border.

It grows naturally in Palestine; also in Spain, Portugal, and some parts of France, and is retained here in our shrubberies as a curiosity; as being supposed to be the plant of which the crown of thorns was composed, to place on the head of our Blessed Saviour at his crucifixion, the probability of which is supported by accounts of some travellers, by observing that the shrub grows naturally in great plenty about Jerusalem and in Judea.

All the above deciduous species flower about June, but the flowers are not ornamental, being small and mostly of a greenish colour, which in the first three species are succeeded by abundance of berries in autumn, effecting a tolerable variety; but the *Palurus* rarely ripens its berries in England.

They are all hardy shrubs, and will prosper in any common soil, and may be planted to increase the variety of the shrubbery and other hardy plantations.

They are propagated by seed and by layers, and sometimes by cuttings.

By Seed.—In autumn, or as soon as the seeds can be procured after they are ripe, sow them in light earth, covering them near an inch deep; they sometimes rise the spring following, if sowed early in autumn, otherwise are apt to remain a year longer in the ground; when however the plants are a year or two old, plant them out in nursery-rows, to have two or three years growth, and then may be planted out finally.

By Layers.—Chuse the young shoots in autumn, and give them either a little twist or nick in the bark at a joint, then lay them in the usual way, they will be rooted in one year.

By Cuttings.—The first three sorts in particular grow by this method; chuse the young twigs for cuttings in autumn, and plant them in rows, most of them will strike.

Evergreen Kinds.

Of these sorts there is but one species common to our gardens, which was formerly a distinct genus (*Alaternus*), but now a species of *Rhamnus*, and comprehends several varieties—all beautiful, hardy, evergreen shrubs.

RHAMNUS Alaternus.

Alaternus.] Rises with a shrubby upright stem, branching numerously all the way from the bottom, from four or five to twelve or

fifteen feet high, the branches having a smooth, greenish, and reddish bark, closely garnished with oval, stiff, shining green, serrated leaves, placed alternately, and at the axillas dioecious greenish flowers in clusters, with three-parted stigmas, succeeded by round soft berries in autumn, having three seeds.

It is a native of the southern parts of Europe.

Varieties.] Large-growing *Alaternus*—Small-growing *Alaternus*—Broad leaved *Alaternus*—Narrow jagged-leaved *Alaternus*—Gold striped-leaved—Silver striped-leaved—Blotched-leaved—Yellow-striped jagged-leaved—White-striped, jagged-leaved—All of which are evergreen shrubs, varieties of the same species, and of hardy growth, succeeding in any common soil in the open shrubberies and other plantations, and exhibit a very ornamental appearance the year round.

This species and the *Phillyrea* bearing a great external resemblance, are often mistaken for one another, but the *Alaternus* in all its varieties have the leaves placed alternately, and the *Phillyrea* in pairs opposite, so that there is a very obvious distinction, besides being of different genera by the characters of their flowers and fruit. See *PHYL-LYREA*.

All the varieties of the *Alaternus* are very ornamental evergreens for adorning the shrubbery and wilderness compartments, and if the plain green sorts and variegated kinds are intermixed in assemblage with other evergreens, they will effect a very distinguishable variety at all seasons: these plants were also formerly used for ornamental hedges, and at present are often employed to form hedges as blinds to hide any naked wall, or other disagreeable fence, &c. in fore-courts and other conspicuous places contiguous to the dwelling; the variegated kinds being mostly used for this purpose, or the green and striped sorts intermixed, which being planted close against the fence, two or three feet asunder, and their branches nailed thereto, they will soon cover it effectually.

They are propagated by seed and by layers; the plain green sorts may be raised by both methods, but the variegated sort by layers only.

By Seed.—The berries ripening abundantly in September or early part of October, should be gathered and sowed as soon after as possible, otherwise they will hardly come up till

till the second spring. Sow them in beds of light mould an inch deep, they will probably come up in the spring; but if not, keep the beds weeded and they will all come up the spring following; which, after having two years growth, transplant them in March in nursery rows, to remain till wanted for the shrubbery, &c.

By Layers — All the sorts may be raised this way, which is the only certain method to continue the variegated sorts. Chuse the young shoots of the year in autumn, give them a slit at a joint, and lay them, they will be most of them well rooted by the autumn following; then take them off and plant them in the nursery way, to have two or three years growth.

Green-house and Stove Kinds

Consist principally of some species of *Zizyphus*, formerly a genus of itself, but now ranged in the family of *Rhamnus*; and the following are cultivated in some gardens for variety.

The two first are green-house plants and the other two for the stove.

¹*RHAMNUS Zizyphus.*

Common Zizyphus, or Fijube-tree.] Rises with a woody stem, branching irregularly eight or ten feet high, armed with strait prickles by pairs; oval, oblong, smooth leaves, and small digynous close-fitting yellow flowers, succeeded by large oval berries.

²*RHAMNUS Fijuba.*

Indian Fijube Tree.] Rises with a shrubby stem, branching eight or ten feet high, armed with solitary or singly-placed recurved spines, roundish retuse leaves, downy underneath, and aggregate pedunculi supporting small, semi-digynous, yellowish flowers, succeeded by large round berries.

³*RHAMNUS Spina Christi.*

Spina Christi, or Ethiopian Fijube.] Rises with shrubby stems dividing into slender branches, armed with strait sharp spines by pairs; oval leaves, and small yellowish flowers.

⁴*RHAMNUS Oenoplia.*

Oenoplia, or Ceylon Fijube.] Rises with a woody stem, branching eight or ten feet high, armed with solitary recurved spines; roundish heart-shaped leaves, and aggregate almost close-fitting pedunculi supporting yellowish flowers.

Of the above four kinds, the two first are for the green-house collection, the other two for the stove; so must always be kept in pots,

and placed among the plants of those departments.

They are propagated by sowing the stones of the fruit in pots, and plunged in a hot-bed.

Likewise by suckers from the root and by layers.

RHEUM, Rhubarb.

The plants are luxuriant herbaceous perennials, of tall upright growth; for variety in gardens and medical purposes; having very thick, fleshy, branched roots; crowned with singularly large, simple, roundish foliage, one or two feet in length and breadth; and strong erect annual stalks, from about three to six or eight feet high, terminated by large spikes of numerous small six-parted flowers.

Class and Order, *Enneandria Trigynia*.

Characters.] *CALIX* none. *COROLLA* is monopetalous, narrow at the base, and impervious, divided above into six parts, alternately smaller. *STAMINA*, nine capillary filaments inserted into the corolla, and terminated by oblong didymous antheræ. *PISTILLUM*, a short triquetrous germen, scarcely visible styles, and three reflexed plumose stigmas. *PERICARPIUM*, none, one large triquetrous, acute seed to each flower, having a membranous border.

There are about five species, all herbaceous and of foreign growth, but grow freely here in the open ground. Are in great estimation as medical plants, the root being the useful part, which however in one or two sorts is of superior quality; one in particular, the *Rheum Palmatum* of *Linnaeus*, is superior to all the others.

¹*RHEUM Rhaponticum.*

Rhaponticum, or Common Rhubarb.] Hath a large, thick, fleshy, branching, deeply-striking root, yellowish within; crowned by very large, roundish, heart-shaped, smooth leaves, on thick, slightly-furrowed foot-stalks: and an upright strong stem, two or three feet high, adorned with leaves singly, and terminated by thick close spikes of white flowers.

It grows in Thrace and Scythia, but has been long in the English gardens; its root affords a gentle purge; is however of inferior quality to some of the following sorts; but the plant being astringent, its young stalks in spring being cut and peeled, are used for tarts.

²*RHEUM Palmatum. (Of Linnaeus.)*

Palmated-leaved True Chinese Rhubarb.] Hath a thick fleshy root, yellow within; crowned

crowned with very large palmated leaves, being deeply divided into acuminate segments, expanded like an open hand; upright stems, five or six feet high or more, terminated by large spikes of flowers.

This is now proved to be the true foreign Rhubarb, the purgative quality of which is well known.

³RHEUM *Compactum*.

Tartarian Rhubarb.] Hath a large, fleshy, branched root, yellow within; crowned by very large heart-shaped, somewhat lobated, sharply indented, smooth leaves; and an upright large stem, five or six feet high, garnished with leaves singly, and branching above; having all the branches terminated by nodding panicles of white flowers.

This has been supposed to be the true Rhubarb, which however though of superior quality to some sorts, is accounted inferior to the *Rheum Palmatum*.

⁴RHEUM *Undulatum*.

Undulated, or waved-leaved Chinese Rhubarb.] Hath a thick, branchy, deep-striking root, yellow within; crowned with large oblong, undulate, somewhat hairy leaves, having equal foot stalks, and an upright firm stem, four feet high, garnished with leaves singly, and terminated by long loose spikes of white flowers.

⁵RHEUM *Ribes*.

Arabian Ribes, or Currant Rhubarb of Mount Libanus.] Hath a thick fleshy root, very broad leaves, full of granulated protuberances, and with equal foot-stalks; and upright firm stems, three or four feet, terminated by spikes of flowers, succeeded by berry-like seeds, being surrounded by a purple pulp.

All these plants are perennial in root, and the leaves and stalks are annual; the roots being thick, fleshy, generally divided, strike deep into the ground; of a brownish colour without, and yellow within; the leaves rise in the spring, generally come up in a large head folded together, gradually expanding themselves; having thick foot-stalks, and grow from one to two feet or more in length and breadth, spreading all round; amidst them rise the flower-stems, which are garnished at each joint by one leaf, and are of strong and expeditious growth, attaining their full height in June, when they flower; and are succeeded by large triangular seeds, ripening in August.

Some plants of each sort merit culture in gardens for variety; they will effect a singu-

larity with their luxuriant foliage, spikes, and flowers.

And as medical plants, they demand culture both for private and public use.

They are propagated by seeds sowed in autumn soon after they are ripe, or early in the spring, in any open bed of light deep earth; remarking, those intended for medical use should generally be sowed where they are to remain; that the roots being not disturbed by removal, may grow large; scatter the seeds thinly, either by broad-cast all over the surface, and raked well in; or in shallow drills a foot and half distance, covering them near an inch deep. The plants will rise in the spring, but not flower till the second or third year; when they however are come up two or three inches high, thin them to eight or ten inches, and clear out all weeds; though those designed always to stand, should afterwards be hoed out to a foot and a half or two feet distance; observing if any are required for the pleasure ground, &c. for variety, they should be transplanted where they are to remain in autumn, when their leaves decay; or early in spring before they shoot; the others remaining where sowed, must have the ground kept clean between them; and in autumn when the leaves and stalks decay, cut them down, and slightly dig the ground between the rows of plants, repeating the same work every year.

The roots remaining, they encrease in size annually; and in the second or third year many of them will shoot up stalks, flower, and perfect seeds; and in three or four years the roots will be arrived to a large size; though older roots are generally preferable for medical use.

RHEXIA, *Rhexia*.

Consists of hardy herbaceous perennials for the pleasure-ground, rising with stalks a foot high, garnished with spear-shaped leaves, and terminated by tetrapetalous, spreading, red flowers.

Class and Order, *Ocandria Monogynia*.

Characters.] CALIX is monophyllous, tubular, ventricose below, four-parted above, and permanent. COROLLA, four roundish patent petals. STAMINA, eight slender filaments inserted in the calix, having declinated linear obtuse versatile antheræ. PISTILLUM, a roundish germen, simple style, and oblong thick stigma. PERICARPIUM, a roundish quadrilocular quadrivalved capsule, in the belly of the calix, having numerous roundish seeds.

There

There are three species, those of our gardens are the two following: both of America.

¹*RHEXIA Virginica.*

Virginia Rhexia.] Rises with an erect tetragonous stalk above a foot high, garnished with spear-shaped, serrated, sessile, opposite leaves; and the stalks terminated by forked pedunculi, crowned with red flowers, having smooth cups.

²*RHEXIA Mariana.*

Maryland Rhexia.] Rises with erect stalks, ten or twelve inches high; having spear-shaped, ciliated opposite leaves, and the stalks terminated by pedunculi, crowned with red flowers.

They both flower in June, but rarely ripen seeds here.

These perennials succeed here in the open ground all the year, in a dry sheltered place, though it is proper to keep some also in pots, to have shelter in very severe frosts.

They are propagated by seed sowed in autumn, or spring, in pots, to be sheltered from frost; or if placed on a hot-bed in March, it will forward their growth; and when the plants are two or three inches high, plant them out.

RHODIOLA, Rose-root.

It is a low, herbaceous, succulent, odorous perennial, for variety in the pleasure-ground, having succulent leaves and stalks, and tetrapetalous dioecious flowers.

Class and Order, *Dioecia Oëlandria.*

Characters.] CALIX, male and female flowers on separate plants, having monophyllous erect, four-parted, permanent cups. COROLLA, in the males, four oblong obtuse petals longer than the calix and deciduous; with four erect nectariums, shorter than the calix; and in the females, four obtuse petals, equal with the calix and permanent, with three or four nectariums like the males. STAMINA, eight subulate filaments longer than the corolla, having simple antheræ. PISTILLUM, four oblong acuminate germens, straight simple styles, having obtuse stigmas. PERICARPIUM, four corniculate capsules opening in the inner side, and many roundish seeds.

There is only one species, grows wild on mountainous parts in England, &c. but has been long a resident of gardens, viz.

RHODIOLA Rosea.

Rhodiola, or Rose-root.] Hath a fleshy, thick, knotty root, emitting an odour like roses; sending up annually erect succulent

stalks, eight or ten inches high, garnished with numerous, oblong, thick, succulent, serrated leaves, alternately; and terminated by clusters of yellowish green flowers.

It flowers in June, and the seeds ripen in autumn.

This plant delights in a dry soil, and may be planted in any of the common borders, where it will abide for years.

It is propagated both by parting the roots in autumn or spring, and by cuttings of the stalks, which being cut off early in the summer, laid in a room a week to dry the succulency of the cut; then plant them in a shady border, and if covered close with a hand-glass, they will strike in less than two months.

RHODODENDRON, Dwarf Rose-bay.

It comprises deciduous and evergreen shrubs for hardy plantations, garnished with lanceolate and oval leaves, and wheel and funnel-shaped flowers in clusters at the ends of the branches.

Class and Order, *Decandria Monogynia.*

Characters.] CALIX, is five-parted and permanent. COROLLA, is monopetalous, wheel or funnel-shaped, five parted, and spreading at top. STAMINA, ten declinated filiforme filaments, having oval antheræ. PISTILLUM, a pentagonous retuse germen, slender style, and obtuse stigma. PERICARPIUM, an oval quinquelocular capsule, having numerous small seeds.

There are about six species, the principal of which in the English gardens, are the following deciduous and ever green kinds.

Deciduous Kinds.

¹*RHODODENDRON Ferrugineum.*

Ferrugineous Dwarf Rose-bay of the Alps.] Rises with a shrubby stalk, branching irregularly, three or four feet high; closely garnished with smallish spear-shaped smooth leaves, ferrugeneous or iron-coloured underneath; and clusters of funnel-shaped red flowers, at the ends of the branches.

²*RHODODENDRON Hirsutum.*

Hairy Dwarf Rose-bay of the Alps.] Hath a shrubby stem, branching numerously about two feet high; oval spear-shaped ciliated, naked leaves, having many iron-coloured hairs underneath, and clusters of funnel-shaped pale-red flowers at the end of the branches.

³*RHODODENDRON Chamæcistus.*

Chamæcistus, or Dwarf Rose-bay of Mount Baldi.] Hath a shrubby stem, branching numerous and irregularly two or three feet high;

small oval, spear-shaped, ciliated leaves, and clusters of wheel-shaped flowers at the end of the branches.

Ever-green Kinds.

¹*RHODODENDRON Maximum.*

Large American Laurel-leaved Rhododendron.] Rises with a shrubby stem, branching eight or ten feet high; large, oval, obtuse, veined, shining, green leaves, the margin acutely reflexed, and pale-red flowers at the ends of branches, each pedunculi having but one flower.

Grows naturally in Virginia.

²*RHODODENDRON Ponticum.*

Pontic Dwarf Rose-bay.] Grows four or five feet high, spear-shaped, smooth, shining leaves, and the branches terminated by clusters of bell-shaped purple flowers.

It grows naturally in humid places in the East, and about Gibraltar.

All these shrubs, both deciduous and ever-green kinds, flower mostly in June; the flowers are monopetalous, funnel and wheel-shaped, in different species, cut at top into five segments; and are sometimes succeeded by seed here in England, especially the second, third, and fourth sorts; the other but seldom.

The plants are all of foreign growth, residents mostly of mountainous, rocky, shady places; and the last generally in moist situations.

They may all be employed to adorn the shrubbery, in which they will appear very ornamental; only they do not thrive so well in our gardens as most other shrubs, unless stationed in soils and situations nearly similar to that where they naturally grow.

They are raised commonly from seeds sowed in autumn, or as soon as they can be obtained, in a shady border; the seeds being very small, make the surface of the ground smooth; sow them thereon evenly, and cover them very lightly with fine mould: they will come up in the spring; and after a year's growth, prick them out into a shady situation.

Their propagation may also be tried by layers of the young wood.

RHUS, Sumach and Toxicodendron, &c.

This genus comprehends many species of the tree and shrub kind, for the shrubbery, green-house, and stove; obtaining from five or six, to ten or twelve feet stature; garnished mostly with pinnate and trefoliate leaves, and

pentapetalous flowers, mostly in clusters at the ends and sides of the branches.

Class and Order, *Pentandria Trigynia.*

Characters.] *CALIX*, is monophyllous, five-parted, and permanent. *COROLLA*, five oval, erect patent petals. *STAMINA*, five very short filaments and small antheræ. *PISTILLUM*, a roundish germen as large as the corolla; scarcely visible styles, but three small heart-shaped stigmas. *PERICARPIUM*, a roundish unilocular berry, some hairy, others smooth in different species, having a roundish hard seed.

To this genus is now added the *Toxicodendron*, or Poison-tree.

There are of the *Sumachs* and *Toxicodendrons* together, about fifteen species, all of which are of the tree and shrub kind, of foreign growth, of different parts of the world; consisting of several hardy deciduous kinds for the shrubbery; several tenderer sorts for the green-house; and one for the stove; the most material species found in the English gardens, are the following.

Hardy Sumach deciduous Kind.

¹*RHUS Coriaria.*

Coriaria, or Tanners Sumach.] Hath a strong woody stem, dividing and branching irregularly, ten or twelve feet high; having a brownish hairy bark; large pinnated leaves, of seven or eight pair of oval bluntly-sawed lobes, terminated by an odd one, and hairy underneath; and large paniculated spikes of whitish flowers at the ends of the branches.

It grows wild in the south of Europe and in Turkey, where the branches are used instead of oak-bark for tanning leather.

²*RHUS Typhinum.*

Virginian Stag's Horn Sumach.] Hath a shrubby stem, branching irregularly eight or ten feet high, having crooked spreading branches, dividing into thick shoots, covered with a soft velvety down, and resemble the form, colour, and texture of a young stag's horn; pinnated leaves of six or seven pair of spear-shaped acutely-sawed lobes, terminated by an odd one, and downy underneath; and at the ends of the branches, large tufts of flowers, succeeded by close downy clusters of purple seeds, having a singular appearance in autumn and winter.

Variety.] Dwarf Virginian Stag's-Horn Sumach.

³*RHUS*

³*Rhus Glabrum.*

Glabrous, or Smooth Sumach.] Consisting of the three following varieties.

New England Smooth Sumach.] Rises with a shrubby stem, branching irregularly from the bottom and sides, twelve or fourteen feet high; having spreading branches, dividing into very thick, somewhat downy, smooth, brown shoots; large pinnated leaves, of ten or more spear-shaped lobes, and an odd one, smooth on both sides; and large loose panicles of greenish flowers at the ends of the branches.

Carolina Smooth Scarlet Sumach.] Grows eight or ten feet high, with smooth purple branches, dusted with a greyish powder; long, pinnated, smooth leaves like the other, and the branches terminated by large scarlet panicles of flowers.

Canada Smooth Red Sumach.] Grows eight or ten feet high, having a purplish bark, tinged with a whitish powder; long pinnated smooth leaves, of a shining green above, and whitish underneath; and the branches terminated by large panicles of red flowers.

⁴*Rhus Copallinum.*

Copallinum, or Lentiscus-leaved American Sumach.] Rises with a shrubby stem, dividing into spreading, smooth, brown branches, four or five feet high; pinnated leaves, of four or five pair of entire lobes, terminated by an odd one; having a membranaceous border running along the foot-stalk in joints, and large loose panicles of greenish flowers at the ends of the branches.

Variety.] Canada Lentiscus-leaved Sumach, growing eight or ten feet high, and larger pinnated leaves.

⁵*Rhus Cotinus.*

Cotinus, Venice Sumach, or Coccygria.] Rises with a shrubby irregular stem, branching widely, about ten feet high, having a smooth brown bark; oval, simple, shining, green leaves; and the branches terminated by long hair-like pedicles, dividing into long hair-like bunches of small purplish flowers.

In Italy and Spain, where this shrub grows naturally, they use the bark for tanning leather.

Hardy Toxicodendron Deciduous Kinds.

These are of the shrub kind and deciduous, natives mostly of America; were formerly ranged as a distinct genus, (*Toxicodendrum*) but are now made species of *Rhus*; most of the sorts abounding with a milky poisonous juice, obtain the appellation of Poison-tree in

America, where they grow naturally in great abundance.

⁶*Rhus Toxicodendrum.*

Common American Toxicodendron, or Poison-Oak.] Hath a low shrubby stem, branching about three feet high, the lower ones trailing and rooting in the ground; ternate or three-lobed leaves, having roundish, angulated, and sometimes entire lobes, each on a short pedicle, and loose panicles of small whitish flowers at the sides of the branches, succeeded by whitish berries in autumn.

Varieties.] Smooth-leaved—downy leaved—upright-growing.

⁷*Rhus Radicans.*

Radicant American Toxicodendron.] Rises with a shrubby stem, branching four or five feet high, having trailing, radican, or rooting branches; ternate smooth leaves, with oval entire lobes, and short spikes of greenish flowers, succeeded by roundish berries in autumn.

Variety.] With upright branches.

⁸*Rhus Vernix.*

Vernix, or Varnish Tree, or Pinnated-leaved American Toxicodendron.] Rises with a strong woody stem, branching thinly on every side, eight or ten feet high; pinnated leaves of three or four pair of oblong entire lobes, and an odd one; and at the axillas, loose panicles of small greenish flowers, and roundish berries, not ripening here. The milky juice of this tree being remarkable for staining, is supposed to be the true Varnish Tree, from which the varnish is collected.

All the above eight hardy species being deciduous, produce their leaves in spring, and shed them in the autumn.

They flower here mostly in June and July, for the general part in clusters and panicles; each cluster composed of numerous small pentapetalous flowers, succeeded in some sorts by seeds, ripening in September.

The plants are all proper furniture for shrubberies, wildernesses, and other ornamental plantations, to encrease the variety of the deciduous collection; they may be planted in any open compartments, in assemblage with other hardy deciduous shrubs, and they will effect a very agreeable diversity in summer, and some sorts also in autumn and winter; particularly some of the Sumach kinds, with their stag-horn, brown, velvety branches, and their large red panicles.

Observe, as several of the Sumachs abound in suckers from the root; and some of the *Toxicodendrons* encrease exceedingly by their trailing;

trailing radicant branches; they should be cleared therefrom every year in winter.

Method of Propagation.

They are all easily propagated by seeds; several sorts also by suckers and their rooting branches; and all the sorts by layers.

By Seed.—Such sorts as do not furnish suckers, &c. may be easily raised from seed, procured from abroad; which should be sowed soon after they arrive, either in large pots or in a bed or border of light earth, and covered half an inch deep; they will sometimes come up in May or June following, though if in pots and plunged in a hot-bed about six weeks, it will forward them, being careful to remove them to the full air soon after the plants appear; however, as those in the natural earth sometimes remain till the spring after, before they vegetate, keep the ground clear from weeds, give water in dry weather in summer, and if a severe winter, give occasional shelter of mats, the first year; and when the plants are one or two years old, plant them out in nursery rows, till large enough for the shrubbery.

By Suckers.—Several of the Sumachs send up abundance from the root; take them up any time in winter, and plant them in nursery rows for a year or two.

By their radicant Branches.—The two first *Toxicodendrons* multiply by their branches, which trail and root in the ground as they advance, which may be taken up in autumn, winter, or spring with roots, and they will form proper plants.

By Layers.—Any of the sorts furnishing lower branches, may have the young wood laid by slit-laying in autumn, and many of them will be rooted in a year.

Most of the species of *Rhus* abound with a milky juice, reckoned more or less poisonous, particularly the *Toxicodendrons*; as a slight touch of the leaves of these sorts cause violent itchings, sometimes followed by an inflammation and swelling; and if the juice of the wood or leaves is suffered to remain on the skin but for a few minutes, it occasions pustules like the itch: it is also said, the wood of the Poison tree when burned, emits a very noxious fume, that will suffocate animals exposed thereto in a room.

Green-house Kinds.

Consists of three African Sumach shrubs, comprehending several varieties; retaining their leaves all the year by shelter of the

green-house in winter, and effect an agreeable variety in that collection.

⁹*Rhus Tomentosum.*

Tomentose, or Downy African Sumach.] Hath a shrubby stem, branching irregularly, six or eight feet high; ternate leaves, downy underneath; composed of angular, rhomboidal, sub-petiolated lobes, downy underneath, and slender bunches of whitish-green flowers from the sides of the branches.

Varieties.] Hairy leaved—Serrated-leaved—Jagged-leaved—Oval-lobed.

¹⁰*Rhus Angustifolium.*

Narrow-leaved African Sumach.] Hath a shrubby stem, and irregular brown branches, growing from five or six, to ten or twelve feet high in the varieties; ternate leaves, having linear-lanceolate, entire, petiolated lobes, downy underneath; and small loose bunches of whitish-green flowers from the sides and ends of the branches.

Variety.] Silvery cut leaved.

¹¹*Rhus Lucidum.*

Lucid, or Shining-leaved African Sumach.] Hath a shrubby strong stem, and irregular brown branches, growing ten or twelve feet high; ternate leaves, having wedge-shaped, sessile, smooth, shining-green lobes; and small bunches of greenish flowers.

Varieties.] Round lobed—Heart-shaped lobed—Dwarf growing.

These three green-house species must be always kept in pots, in order for moving to shelter in winter, managing them as other shrubby plants of the green-house collection. See GREEN-HOUSE PLANTS.

They are easily propagated by layers and cuttings.

By Layers.—In spring, lay any of the lower young wood in the common way, and they will be rooted and fit to pot off in autumn.

By Cuttings.—Plant cuttings of the young shoots in April, May, or June, in pots; and if plunged in any hot-bed, they will soon strike, giving occasional shade and watering, and towards autumn pot them off separately.

Stove Kinds.

¹²*Rhus Cobbe.*

Cobbe, or Ceylon Sumach.] Hath a shrubby stem, branching eight or ten feet high; ternate leaves, having oval, acuminate, sawed lobes, and clusters of whitish-green flowers at the ends of the branches, having downy peduncles.

It

R I B

It is a tender exotic, requiring a stove in this country, so must always be kept in pots, and placed in that department and managed as other shrubby hot-house plants.

Propagate it by cuttings in the spring, planted in pots, and plunge them in a bark-bed.

RIBES, Currant-tree and Gooseberry-bush.

The Currant and Gooseberry are hardy deciduous shrubs, species of the same genus, each comprising many varieties, all of bushy growth; garnished with trilobate simple leaves, and very small pentapetalous flowers from the sides of the branches; some in racemous clusters, others singly, succeeded by globular berries, valuable as early summer fruit for the desert; also for various culinary purposes, and some for medical uses.

Class and Order, *Pentandria Monogynia*.

Characters.] CALIX, is monophyllous, ventricose, cut into five concave segments, and permanent. COROLLA, five small obtuse petals attached to the border of the calix. STAMINA, five subulate filaments inserted in the calix, having incumbent compressed anthers. PISTILLUM, a roundish germen under the flower, bifid style, and obtuse stigma. PERICARPIUM, a globose, umbilicated, unilocular berry, full of pulp, and many roundish compressed seeds.

The Currant and Gooseberry were long considered each as a separate genus; *Ribes* the Currant, and *Grossularia* the Gooseberry; but agreeable to systematic botany, they are now joined together, the *Grossularia* being made a species of *Ribes*; all the Currantkinds having inermous or thornless branches, and racemous clusters of flowers and fruit; and the Gooseberry have spinous branches, and flowers and fruit for the most part singly.

Currant Kinds.

There are three species of the Currant-tree, two of which and their varieties, merit culture for their fruit; the other as a plant of variety or observation; all of which are inermous or unarmed, having no thorns on the branches.

¹RIBES *Rubrum*.

Common Red Currant-tree, &c.] Hath a shrubby stem, dividing low into many branches, forming a bushy head, five or six feet high, or more, without thorns; broad trilobate leaves, and smooth pendulous clusters of plane greenish flowers, succeeded by clusters of small berries.

It grows naturally in woods and hedges in England, and most parts of Europe.

R I B

Varieties.] Comprises all the sorts of Red and White Currants, as, Common, small, Red Currant—Large Red Dutch Currant—Long bunched Red Currant—Champagne Pale-red Currant—Common small White Currant—Large White Dutch Currant—Yellow blotched leaved Currant—Silver striped-leaved—Gold striped leaved—Gooseberry-leaved.

All these sorts are varieties of one species: *Ribes Rubrum*, or *Common Red Currant*, it being the parent from which all the others were first obtained from the seed, and improved by culture; they all flower in the spring, and the fruit ripens in June and July; and by having the trees in different situations and modes of training, such as plantations of standards in the open quarters, for the general supply, others trained against walls or pales, of different aspect, the fruit may be continued ripe in good perfection, from about the middle of June until November, provided the later crops are defended with mats or nets from the birds: the ripe fruit of all the varieties are valuable, not only to eat raw, as being of an agreeable, quick, acid relish, and fine cooling quality, excellent to quench thirst and create an appetite; but the red sorts in particular are made into gellies, tarts, sauces, and other culinary preparations. Likewise, of Currants is made good wine, and they are also used in medicine; so that plenty of the trees should be cultivated in every garden for the fruit, both for private use and the supply of markets: as to the variegated-leaved kinds, they are valued as furniture for the shrubbery, to cause diversity in the different variegations of their leaves; they also bear fruit plentifully like the other kinds; and all the varieties of every sort are very easy of propagation and culture, by cuttings, suckers, and layers. See their *Propagation*.

²RIBES *Nigrum*.

Black Currant-tree.] Hath a shrubby stem, dividing low into many branches, forming a bushy head, five or six feet high; broad trilobate leaves of a rank odour, and having racemous clusters of oblong greenish flowers, succeeded by thin clusters of black berries.

The fruit of this species being of a strong flavour and somewhat physical relish, is not generally liked; it however is accounted very wholesome, and of which is also made a syrup of high estimation for sore throats and quinseys; hence the fruit is often called squinaney berries.

Variety.] *Pennsylvanian Black Currant.* Having smaller shoots and leaves; not strong scented, and small fruit of but little value; so the shrub is esteemed only for variety in shrubberies.

The mode of bearing of all the varieties of Currants, is both on the old and young wood, all along the sides of the branches and shoots, often upon a sort of small spurs and snags, producing the fruit in numerous long pendulous clusters.

Grossularia, or Gooseberry Kinds.

Of the *Grossularia* or Gooseberry kinds, there are four or five species, comprehending many varieties, all of which are of bushy growth, from about three or four, to six or seven feet high; some being upright, others of reclinated growth; have all their branches armed with spines, and produce their fruit both on the young and old wood, all along the sides of the branches and shoots; sometimes immediately from the eyes or buds, of the young wood in particular, and also on small spurs on the older branches; in all of which the flowers and fruit arise, some singly, others in small bunches; all of the berry kind; useful both when green and ripe; green, for tarts, pies, sauces, and for preserving in bottles for winter use; and when ripe, it is valuable as an early desert fruit; and the different sorts afford great variety at table, in their different colours and relishes.

¹*RIBES Grossularia.*

Grossularia, or Common Gooseberry-bush.] Rises with a low shrubby stem, dividing low into a very branchy bushy head, armed with spines; trilobate smallish leaves, having hairy ciliated foot-stalks, and small greenish flowers, succeeded by hairy berries.

Varieties.] Consists of many varieties of different sizes and colours, as hereafter described.

²*RIBES Reclinatum.*

Reclinated broad-leaved Gooseberry-bush.] Rises with a low shrubby stem, and reclinated somewhat prickly branches; trilobate broadish leaves, and small greenish flowers, having the pedunculi furnished with triphyllous bractea.

³*RIBES Oxyacanthoides.*

Oxyacantha-leaved Gooseberry.] Hath a shrubby stem, and branches armed on all sides with spines; and largish trilobate hawthorn leaves.

⁴*RIBES Uva crispa.*

Uva crispa, or Smooth Gooseberry.] Hath a shrubby stem and branches, armed with spines;

trilobate leaves; pedicles having monophyllous bractea; and smooth fruit.

⁵*RIBES Cynosbati.*

Prickly-fruited Gooseberry-bush.] Hath a shrubby stem and branches, armed with spines mostly at the axillas; and prickly fruit in clusters.

Varieties of the different species.] Many varieties of Gooseberries have been raised from seeds; some having round berries, others oval; some hairy and some smooth, and of different colours, as Red—Green—Yellow—White, &c. consisting of the following varieties of each sort

Red Kinds.—Hairy Red Gooseberry—Smooth Red Gooseberry—Deep Red Gooseberry—Damson, or Dark-red blueish Gooseberry—Red Raspberry Gooseberry—Early Black-red Gooseberry.

Green Kinds.—Hairy Green Gooseberry—Smooth Green Gooseberry—Green Gascoigne Gooseberry—Green Raspberry Gooseberry.

Yellow Kinds.—Great oval Yellow Gooseberry—Great Amber Gooseberry—Hairy Amber Gooseberry—Early Amber Gooseberry.

White Kinds.—Large White Crystal Gooseberry—Common White Gooseberry—White-veined Gooseberry.

Other Varieties of different Sorts.] Champagne Gooseberry—Rumbullion Gooseberry—Large Ironmonger Gooseberry—Smooth Ironmonger Gooseberry—Hairy Globe Gooseberry—Large Tawney, or Great Mogul Gooseberry.

All the above seven species of *Ribes*, both Currant and Gooseberry kinds and their respective varieties, are very hardy shrubs, that prosper almost any where, both in open and shady situations, and in any common soil; bearing plentifully in any exposure, though in open sunny situations, they produce the largest and fairest fruit, ripening to a richer vinous flavour; but it is eligible to plant them in different situations and aspects, in order to have the fruit as early and late as possible.

They are commonly planted in the kitchen garden mostly as dwarf standards, in the open quarters, for the general supply; being disposed sometimes in continued plantations in rows, eight or ten feet by six asunder, where great quantities of the fruit are required for market or other large supplies; and are sometimes disposed in single ranges round the outward edge of the quarters, eight feet asunder; frequently in single cross rows, in order to divide the ground into separate wide plats or breaks,
of

of from twenty to thirty or forty feet width; which also serves to shelter the ground a little in winter; in all of which methods of planting them as standards, they should be generally trained up to a single stem about a foot high, then suffered to branch out every way all around into bushy heads, keeping the middle however open, and the branches moderately thin, to admit the sun and free air; though if some are fanned, that is, trimmed on two sides oppositely, so as to make the other branches range in a line like an espalier, whereby they will take up much less of the ground, and, by admitting the sun and air more freely, they will produce large fair fruit.

They are likewise trained against walls or palings, like other wall trees; but principally some of the large red and white Dutch Currants, in which they will produce fine large fruit, and those against any south fence will ripen early and be high flavoured; but it is proper to plant a few both against south, north, east, and west walls, in order to obtain the fruit ripening both early and late, in a long succession. It is also proper to plant a few of the finest sorts of Gooseberries against a warm fence, both to have early green Gooseberries for tarts, &c. as well as to ripen early; and they will grow very large and fine.

Sometimes both Currants and Gooseberries are also trained in low espaliers for variety, and they produce very fine fruit.

All the varieties of these shrubs are raised plentifully in the nurseries for sale.

Method of Propagation.

All the sorts of Currants and Gooseberries are expeditiously propagated by cuttings, suckers, and layers; but as every cutting and slip will most readily grow, that mode of propagating them is most commonly adopted in the nurseries, in raising great quantities for sale.

By Cuttings. — Autumn, at the fall of the leaf, is the most eligible season for planting the cuttings; it may also be performed any time in winter, in open weather, and early part of the spring; choosing the young shoots of last summer, cutting them off from about ten or twelve to eighteen inches long, and plant them in any shady border, in rows a foot asunder, each full half way into the ground; they will root firmly the ensuing summer, shoot at top, and form tolerable little plants by next autumn, when every other row may be thinned

out, and planted in nursery lines two feet and half asunder; afterwards train the whole for the purposes designed.

Observe those designed for common standards, should be trained up to a twelve or fifteen inch stem, then encourage them to branch out all around at that height to form a full head; for if suffered to branch away immediately from the bottom, according to the natural mode of growth of these kind of trees, as is often the case in many gardens, they overspread the ground, that no crops can grow near them, as well as appear unsightly, and render it inconvenient to do the necessary work: it is therefore of importance to keep them to a single stem, a foot at least high, then suffered to form the first set of branches, trimming off low stragglers, and encourage the more upright growths; thinning them to moderate distances, and reduce long ramblers to preserve a somewhat regular head; the trees will thus assume a decent appearance, admit of small crops under them, and will be more easily kept in regular order.

And if intended to train any of them with fanned branches, either for fanned standards, or for walls and espaliers, they must be encouraged to branch out near the bottom, and ranged the way of the rows, cutting off all cross or foreright shoots, so as to form the branches in a straight range, like an espalier, &c.

In all the above modes of training these shrubs, by cuttings, they will attain a bearing state in two or three years.

By Suckers. — All the sorts send up suckers very plentifully from the roots, each sucker forming a proper plant, and is the most expeditious mode of propagating all the varieties, both Currants and Gooseberries; they may be taken up in autumn, winter, or spring, with roots, or even such as are without fibres will succeed; for the lower part having been situated in the ground, is naturally disposed to send out fibres very soon; planting them either in nursery rows for a year or two, or such as are tall and strong may be planted at once where they are to remain: observing to train the whole for the purposes intended, as directed for the cuttings, and they will form bearing plants after one or two years growth.

But the propagating them by suckers, is by some objected to, as alledging they incline to run greatly to suckers again, and encumber the ground; there is however, but little foundation in this, for it is peculiar to these shrubs,

them be raised either by seeds, cuttings, or any other method, they are naturally disposed to send up many suckers from the roots annually. See SUCKERS.

Sometimes these shrubs having been permitted to advance with several stems, formed by suckers that have arisen directly from the root; the whole forming a large spreading bush; which, if taken up may be divided into several separate plants, with good roots and branchy heads, and planted out finally to remain; they will at once commence good bearing plants, producing fruit the following summer.

By Layers.—The young branches being laid any how, in autumn, winter, or spring, will readily strike root, and next autumn be fit to transplant.

In the general propagation of these shrubs, we would observe, that, as they naturally throw out many suckers from the root, so as often to become troublesome, it is proper, previous to planting the cuttings, and suckers, &c. to rub off close all the buds or prominent eyes, from the lower part, as far as they are to be put into the ground, which will in some measure diminish their tendency in the production of suckers: likewise, when transplanting the young plants, if they discover any tendency to the bottom for suckers, let all such parts be also carefully rubbed off close.

Final Transplantation.

When these shrubs are grown about two or three feet high, having tolerable heads, they are of a proper size for transplanting finally, into the garden where they are to remain for bearing.

They may be transplanted any time from October until March, in open weather.

Plant them in rows, eight or ten feet distance, both as standards and for walls, &c. observing to plant the principal quantity as standards for the general supply, and a few of the choicer sorts for walls, particularly of the Currants.

In planting them for standards, if a full or continued plantation of them is intended, set them in rows eight or ten feet asunder, as above observed; and six distant in the ranges; and if designed in single rows, either round or cross ways the quarters, allow full seven or eight feet distance, for if closer, they will soon meet and prove troublesome.

And in planting them against walls or espaliers, let some be planted against a south wall, to produce early fruit; others on a north; and

other aspected fences; allowing them eight or ten feet distance, as aforesaid, and train their branches four or five inches asunder.

General Culture.

Their culture in common Standards.—Continue to train them with a single stem, a foot high, as already hinted; and let the head branch out four or five feet high, keeping the middle somewhat hollow, and the branches at tolerable distances, by occasional pruning, not with garden sheers, but regularly with a pruning knife; observing however, if the plants are permitted to aspire in height, shoot at full length, and take their own natural growth, they will grow higher and more spreading, and shoot more moderate, than if pruned annually, and will also bear plentifully without trouble; though if they are kept down by proper pruning, to about four feet height, the middle kept open, and the branches thin, at some reasonable distances, they will probably produce larger fruit, ripening sooner, and with a better flavour; but remarking, in this case, that by the annual pruning to keep the shrubs low and regular, it causes them to throw out numerous shoots every summer, and crowd them with useless wood, which must be regulated accordingly, by pruning them every winter, to retrench all that are evidently superfluous, and reserving others occasionally in proper places for young bearers, and to cut out irregular crowding branches occasionally.

This pruning is performed in winter, or any time from the fall of the leaf till February. With your knife retrench all superfluous shoots of last summer from the middle of the plants, and from the sides of the branches in general, only reserving a terminating shoot to every branch, and some regular shoots occasionally towards the lower parts, either to be coming forward for young bearers, or to fill any present or apparently future vacancy; or to supply the place of any worn out branches, or dead wood, which should always be retrenched, and some contiguous shoots retained in its stead, and clear the bottom from all suckers, &c.

At the same time observing, that when the branches in general become too numerous and crowding, or grow across, or in any very irregular growth, to cause confusion and disorder, they should also be regulated by pruning out the most irregular, leaving the others five or six inches asunder; likewise, retrench all low stragglers; and according as any of the branches

branches become too long, or advanced higher than you intend, or any long Rambler happening, they should be reduced to order, by shortening them down to some convenient young shoot, or lower young branch terminated by one; for in reducing or shortening the branches, as occasion may require, they should not be stumped off, but pruned down to a young shoot or branch; as just hinted; that they may still terminate in a young shoot for a leader.

The general supply of young shoots may be more or less shortened, according to their strength and situation, but more particularly the currants, if thought necessary to keep the head low and within small compass; cutting the upper shoots to six, eight, or ten inches; but the lower ones designed to grow up to fill any vacancy, leave longer in proportion, or at full length, as it shall seem proper, till arrived to the desired height.

But the Gooseberry kinds having the young wood much shortened, it causes them to throw out very numerous shoots in summer, and crowd the bushes exceedingly with unnecessary wood, it is therefore eligible to shorten the shoots of these kinds but moderately, or leave them mostly entire, or at full length; such however, as recline considerably, or ramble away from all the rest, should be reduced with the knife, so as to preserve a little regularity in the head.

To conclude, be careful always, both in the Currant and Gooseberry kinds, not to suffer them to become of straggling growth, spreading near the ground, nor too much crowded at top; but annually clear off all suckers from the bottom, all lower straggling shoots from the stem, and keep the middle of the head open, and the branches in general thin, about six or seven inches asunder, as aforesaid, preserving all the small laterals bearing snags, natural spurs and fruit-buds; and thus these shrubs will always bear large and fair fruit in great abundance.

Their culture in fanned Standards.—If intended to fan any of them in standards, ranging the branches in the manner of espaliers, you must encourage only the branches that range the way of the rows, trimming off all fore and back shoots, and range the others about six inches asunder, at full length, till those of each tree nearly approach, giving occasional pruning both in summer to retrench all superfluous and projecting foreright shoots; and in winter to give a general regulation as observed for the common bush standards.

Training them against walls and espaliers.—

Let them branch out near the bottom, as formerly noticed in the nursery culture, clearing off all foreright growers, and train the others horizontally to the wall, &c. five or six inches asunder, at full length, till they have filled the allotted space; they will naturally form fruit-buds all along their sides, and bear abundantly. Observe to give them a summer and a winter pruning; in summer to retrench close all foreright, and evidently superfluous shoots, and train in only an occasional supply of some of the most regular shoots towards the lower parts till winter, in case of a vacancy, or to be in training for young bearers; and if then not wanted, must be displaced; and by this regulation in summer, it not only preserves the uniformity of the trees, but exhibits the fruit to view, and gives access to a due portion of sun and air to improve its growth and flavour. And in winter pruning, see if there are any vacancies, and retain some contiguous shoot left in summer, cutting out any worn out or naked branch, down to some lower shoot or young branch, as observed of the standard bushes; looking occasionally to the lower part of the trees for any well placed strong shoots, and see if they are wanted either to fill a present vacancy, or for training in to serve future purposes to supply the place of any old branch becoming naked, or unfurnished with bearing parts; in which cases, retain occasional supplies of young wood as you shall see necessary, keep all the main branches at regular distances, preserving all the spurs and fruit-buds, but cut off any long projecting snags, and all dead wood. Then train the whole straight and close to the wall at the distances afore-mentioned.

These trees thus properly trained against walls, will grow eight or ten feet high, and extended widely every way.

Of the Fruit.

The fruit of all the varieties, both Currants and Gooseberries, on standards and against walls, begin to ripen in June, but do not attain full perfection till July; those against warm walls ripen soonest by a fortnight, if the trees are properly dressed in summer, and will be succeeded by the standards for the general crop.

When designed to continue a supply of these fruit, as long in the season as possible, it is proper to net some of the fullest trees, when they begin to ripen, to defend the berries from the birds; and mat others to shade them from the sun

sun, in order to retard their ripening. And if when full ripe, some are closely matted with large mats, particularly Currants, it will preserve the fruit in perfection on the trees till October or November.

RICINUS, *Palma Christi*.

Consists of tall, herbaceous, tender annuals for the pleasure ground, rising with strong erect stems from three or four to ten or twelve feet high, adorned with luxuriant, palmated, peltated leaves, on long foot-stalks, and long spikes of apetalous monoecious flowers, in July and August.

Class and order, *Monoecia, Monadelphica*.

Characters.] **CALIX**, male and female flowers, apart in the same spike; the males having monophyllous, five-parted cups, and those of the females three-parted, and deciduous.—**COROLLA**, no petals.—**STAMINA**, numerous filiforme filaments, variously connected in the monadelphous way, terminated by roundish didymous antheræ.—**PISTILLUM**, an oval covered germen, three bifid, erect-patent styles, crowned by simple stigmas.—**PERICARPIUM**, a roundish trifurcated, trivalved, trilocular capsule, each cell having a single oval seed.

There are three species, one of which only is common to our gardens, comprehending several varieties, some growing eight or ten feet high, others not above half so much, esteemed as ornamental plants for the singularity of their large, beautiful leaves, from one to two feet and half broad, deeply lobated into six or seven segments, expanded in the palmated way, and the foot-stalks, fixed in the middle underneath, in the peltated manner. See **FOLIUM**.

The species is

RICINUS *Communis*.

Common Palma Christi.] Rises with an upright, strong, herbaceous, jointed stem, eight or ten feet high; having sub-palmated, peltated sawed leaves, and at the axillas, long spikes of whitish-green flowers, succeeded by ripe seeds in autumn.

Varieties.] There are many varieties, formerly supposed to be distinct species, but are found to be all varieties only of *Ricinus Communis*—and of which there are—*Major Palma Christi*, growing from about six or eight to ten or twelve feet high.—*Minor Palma Christi*, growing but three or four feet high—green-stalked—grey-stalked—brown-stalked—red-stalked, &c.—broad-leaved, being more than two feet in breadth—lesser-leaved, being from ten or twelve to fifteen or eighteen

inches wide—deeply divided-leaved—slightly divided-leaved—grey-leaved—green-leaved—six-lobed-leaved—seven-lobed-leaved, &c. being all varieties of one species, which, and its varieties in general, are annual or biennial, natives of Africa, America, and the South of Europe, and require a hot-bed to raise them in this country.

They are fine majestic plants, annual, or at most biennial in England; but in their native soil, it is said, they are durable both in root and stem. In England however, we consider them only as annuals, for being raised from seed in the spring, they shoot up to stem, flower, and perfect seeds the same year, and, if not sheltered, die root and all in the winter; but being sheltered in a green house, or stove, during that season they will abide two years.

Their merit in our gardens is as ornamental plants, being raised first in a hot-bed, then transplanted into the borders in summer, they will effect a fine variety.

Their Propagation, &c.

They are raised from seed sowed in any hot-bed with other tenderish annuals, such as Africans, China asters, &c. half an inch deep: when they are come up three inches high, pot some of them separately in small pots, which plunge also in a hot-bed; others prick in the earth of the bed, giving plenty of water, and according as they encrease in size, shift those in pots into larger sizes; and about the end of May, or beginning of June, remove all of them into the full air, transplanting some with balls about their roots into the open borders, and retain some in pots to move occasionally, where wanted: supplying the whole with water in dry weather, particularly the transplanted plants in the borders, &c. till firmly rooted, and the potted plants all the summer, about three times a week. Thus these fine plants will grow to their full height in August, well cloathed with their noble foliage, and will produce flowers and seed.

If intended to preserve any in the greenhouse all the winter for variety, chuse some of the handsomest potted plants, which remove into that repository in October, where they will retain their stems and leaves.

RIDGING Ground.—See **DIGGING by Trenches**, and **TRENCHING**.

RIVINIA, *Rivinia*.

Two shrubby ever-greens for the stove compose this genus: one a low upright plant, the other a high climber; furnished with heart-shaped

shaped and oval leaves, and spikes of small apetalous flowers.

Class and order, *Tetandria Monogynia*.

Characters.] CALIX, four oblong-oval, coloured, permanent leaves.—COROLLA, no petals.—STAMINA, four and some eight permanent filaments, having small antheræ.—PISTILLUM, a large roundish germen, short style, and obtuse stigma.—PERICARPIUM, a globular unilocular berry lodged close in the calix, having one roundish seed.

The species are.

¹RIVINIA *Humilis*.

Dwarf Tetrandrous Jamaica Rivinia.] Hath a low shrubby stem, dividing and branching three or four feet high; heart-shaped leaves, and long spikes of small tetrandrous flowers, succeeded by red berries.

Varieties.] Downy-leaved — white-flowered — scarlet-flowered.

²RIVINIA *Octandria*.

Climbing Octandrous American Rivinia.] Rises with a shrubby, climbing, branchy stem, fifteen or eighteen feet high. Oval spear-shaped leaves, and loose spikes of small octandrous flowers, succeeded by blue berries.

Both the species are ever-green, and being tender exotics from the warmest parts of America, must be kept always in pots, and placed among the stove plants, where they will flower most times of the year: the flowers are apetalous, separately small, but numerous in each spike, arising in great abundance from the sides and ends of the branches, succeeded by berries.

They are raised from seed sowed in pots, and plunged in a bark-bed. Try them also by layers and cuttings, assisted by heat.

ROBINIA, *False Acacia*.

Consists of hardy deciduous trees and shrubs for ornamental plantations, and tender kinds for the hot-house collection; adorned with pinnated and quaternate leaves; and pendulous clusters of papilionaceous flowers.

Class and order, *Diadelphia Decandria*.

Characters.] CALIX is monophyllous, and four-parted, having the three under-segments narrow, the other broad.—COROLLA, is papilionaceous, having a large round patent vexillum, two oval wings, with short appendices, and a nearly semi-orbicular depressed carina.—STAMINA, ten diadelphous filaments, and roundish antheræ.—PISTILLUM, a cylindric oblong germen, slender bent style, and hairy stigma.—PERICARPIUM, a large oblong compressed pod, having kidney-shaped seeds.

There are six species, all of the tree and

shrub kind, four of them hardy for the shrubbery, and two tender for the stove.

Hardy Kinds.

These consist of one large tree, and three moderate shrubs, all deciduous, natives of foreign parts, America, Siberia, and Tartary, but all hardy enough to succeed in our open plantations.

¹ROBINIA, *Pseud-Acacia*.

Common Pseud-Acacia, False-Acacia, or American Robinia.] Rises with a strong, woody trunk, dividing and branching thirty or forty feet high; armed with strong spines; large, long, pinnated leaves of nine or ten pair of oval lobes, and an odd one, having prickly stipulæ, and long pendulous racemous clusters of papilionaceous, white, odoriferous flowers, one on each pedicle, succeeded by smooth seed-pods.

Varieties.] Consists of the two following, formerly considered as distinct species, viz.

Echinated, or Prickly-podded American False-Acacia.] Grows thirty or forty feet high, having leaves and flowers like the other, but short very prickly pods.

Rose Acacia, or Hispid American Robinia.] Grows fifteen or twenty feet high, but appears like a moderate shrub in England, armed with spines, and hispid hairs on every part, having leaves and flowers formed like the other: but the flowers are of a beautiful rose-colour, making a fine appearance.

This is a very beautiful flowering shrub, for the principal compartments of the shrubbery.

²ROBINIA, *Caragana*.

Caragana, or Siberian Robinia.] Rises with a shrubby stem, branching eight or ten feet high, or more: abruptly pinnated leaves of five or six pair of oval lobes, not terminated by an odd one; and simple or unbranched pedunculi, sustaining small yellow flowers.

³ROBINIA *Frutescens*.

Shrubby Quaternate-leaved Siberian Robinia.] Hath a shrubby stem, branching six or eight feet high, quaternate oval leaves, on short foot-stalks: and simple pedunculi, sustaining yellow-flowers.

⁴ROBINIA, *Pigmæa*.

Dwarf quaternate leaved Siberian Robinia.] Hath a low shrubby stem, branching about three feet high. Quaternate, wedge-shaped, close-fitting leaves; and simple pedunculi, sustaining yellow-flowers.

The above four hardy species flower here annually, the first sort in June, and the others in May. The flowers are all papilionaceous and

and tetrapetalous; arising from the sides and ends of the branches; which in the first sort and varieties being produced in long clusters, make a fine appearance, particularly the variety *Rose Acacia*; and most of the sorts are succeeded by seed-pods, ripening in September, particularly the last three species.

They are all proper furniture for embellishing the shrubberies, will succeed any where, and exhibit a fine variety with their pinnated and quaternate leaves, and the *Pseud-Acacia*, and varieties, also with the numerous clusters of flowers.

Hot-house Kinds.

Consists of two tree and shrub species, natives of the warm parts of America and India.

⁵*ROBINIA Violacea.*

Violet American Robinia.] Hath a woody trunk, branching twenty feet high: pinnated leaves of eight or ten pair of oval lobes, and an odd one: and clusters of violet coloured-flowers, two on each pedicle.

Varieties.] With dark-blue-flowers—scarlet-flowered—and with leaves having spear-shaped lobes—oblong lobes, &c.

⁶*ROBINIA Mitis.*

Smooth Indian Robinia.] Hath a smooth shrubby-stem, and taper branches; pinnated leaves, of several pair of oval lobes, and an odd one; and clusters of whitish flowers, three on each pedicle.

All the four hardy species being for the shrubbery, may be had at the nurseries, particularly the first sort and varieties, and the *Caragana*: and may all be planted in any common soil and situation.

But the two tender species must always be kept in pots, and placed in the stove.

Method of Propagation.

The hardy kinds are raised from seeds, cuttings, layers, and suckers.

By Seeds.—In March, sow them in any bed of light mould, half an inch deep: the plants will come up in less than two months, the first species and varieties in particular, the others sometimes not till spring after, unless sowed in autumn: give occasional weeding and watering, and in the spring following plant them out in nursery rows, to have two or three years growth.

By Cuttings.—In October or November, having a quantity of cuttings of the young

shoots, plant them in a shady border, and they will be rooted well in one year.

By Layers.—Lay the young wood in autumn, they will be rooted by autumn following.

By Suckers.—The first species generally send up plenty from the root, which transplant any time from October till March.

The tender sorts are raised from seed cuttings and layers, assisted by artificial heat.

ROSA, Rose-Tree.

This noted genus comprehends numerous deciduous flowering shrubs, and an evergreen; all of hardy growth, and the pride of the shrubby-flowering tribe, for adorning the pleasure-grounds, &c. with their large elegant flowers, in great profusion, for several months in summer; are garnished with pinnated rough leaves, of from three to five or seven lobes; and numerous large pentapetalous, very odoriferous flowers, comprising many double varieties of singular beauty.

Class and order, *Icosandria Polygynia*.

Characters.] *CALIX* is monophyllous, ventricose, and fleshy below, and divided at top into five long, narrow, spear-shaped segments, two of which alternately, having appendices on their sides, two alternately naked, and the fifth sometimes appendiculated on one side only.—*COROLLA*, five obversely heart-shaped petals, inserted into the calix.—*STAMINA*, numerous short capillary filaments, inserted into the neck of the calix, and trigonous antheræ.—*PISTILLUM*, numerous germina in the bottom of the calix, and numerous very short hairy styles, straitly compressed in the neck of the calix, and inserted into the sides of the germen, crowned by obtuse stigmas.—*PERICARPIUM*, the fleshy base of the calix becomes a turbinated, fleshy, soft, unilocular berry, having numerous oblong hairy seeds, fastened on each side to the calix.

The sorts of Roses are very numerous, and the botanists find it very difficult to determine, with accuracy, which are species, and which varieties, as well as which are varieties of the respective species, on which account Linnaeus, and some other eminent authors, are inclined to think that there is only one real species of Rose, which is the *Rosa Canina*, or Dog-Rose of the hedges, &c. and that all the other sorts are accidental varieties of it; however, according to the present Linnæan arrangement, they stand divided into fourteen supposed species, each described to have some particular mark of distinction, though in several sorts, is not very conspicuous, and agreeable to the specific

specific description of the several species, each comprehends some varieties, which, in some sorts are but few, others numerous.

The supposed species, and their varieties, according to the arrangement of modern botanists, are as follow :

¹*Rosa Canina.*

Canine Rose, or Wild Dog-Rose of the Hedges, or-Hep-tree.] Grows five or six feet high, having prickly-stalks and branches, pinnated, five or seven-lobed leaves, with aculeated foot-stalks; smooth pedunculi; oval, smooth germina, and small single-flowers.

Varieties.] Red-flowered canine Rose—white-flowered.

They grow wild in hedges abundantly all over the kingdom: and are sometimes admitted into gardens, a few to increase the variety of the shrubbery collection.

²*Rosa Alba.*

Common White-Rose.] Grows five or six feet high, having a green stem and branches, armed with prickles; hispid pedunculi; oval smooth germina, and large white flowers.

Varieties.] Large double White Rose—semi-double White Rose—dwarf single White Rose—maidens-blush White Rose, being large, produced in clusters, and of a white and blush red-colour.

³*Rosa Gallica.*

Gallican Rose, &c.] Grows from about three or four to eight or ten feet high, in different varieties, pinnated three, five, or seven lobed leaves, and large red, and other coloured-flowers in different sorts.

The specific description is:—Rose, with hispid, prickly branches, and petioles; hispid pedunculi, and oval hispid germina.

Varieties.] This species is very extensive in supposed varieties, bearing the above specific distinction, several of which have been formerly considered as distinct species, but now ranged among the varieties of the Gallican Rose, consisting of the following noted varieties.

Common Red Officinal Rose.] Grows erect, about three or four feet high, having small branches, with but few prickles; and large, spreading, half-double, deep-red flowers.

The flowers being astringent, are used in medicine, being gathered for that use while in the bud, or before they begin to open; and they fetch a good price at market, where they are sold by the peck, or bushel, and pay sufficiently for the culture of a large quantity of plants, for which purpose the London gardeners plant them in close ranges, forming low hedges, a foot or two high, keeping them

down by an annual clipping in autumn; and they produce great quantities of flowers.

Rosa Mundi, (Rose of the World) or striped Red Rose.] Is a variety of the common Red Rose, growing but three or four feet high; having large spreading semi-double red flowers, beautifully striped with white—and deep-red.

York and Lancaster variegated Rose.] Grows five, six, or eight feet high, or more; bearing variegated red flowers; consisting of a mixture of red and white; also frequently disposed in elegant stripes, sometimes in half of the flower, and sometimes in some of the petals.

Monthly Rose.] Grows about four or five feet high, with green, very prickly shoots; producing middle sized, moderately-double, delicate flowers, of different colours in the varieties.

Varieties are.] Common red-flowered Monthly Rose—blush-flowered—white-flowered—striped-flowered—All of which bloom both early and late, and often produce flowers several months in the year, as May, June, and July: and frequently again in August, or September, and sometimes in fine mild seasons, continues till November or December: hence the name Monthly Rose.

It is generally the earliest blowing Rose; but as it begins to shoot early in the spring, the buds are often cut by the frost, so as to prevent their blowing fair and plenteously; the plants should therefore have a somewhat sheltered warm situation; some should also be planted against a warm wall; and is a proper sort to pot for forcing.

Double Virgin Rose.] Grows five or six feet high, having greenish branches with scarce any spines; and with large, double, pale-red, very fragrant flowers.

Red Damask Rose.] Grows eight or ten feet high, having greenish branches, armed with short aculea; and moderately-double, fine soft-red, very fragrant flowers.

White Damask Rose.] Grows eight or ten feet high, with greenish very prickly branches, and whitish-red flowers, becoming gradually of a whiter colour.

Blush Belgic Rose.] Grows three or four feet high, or more; having greenish prickly branches, five or seven lobed leaves, and numerous, very double, blush-red flowers, with short petals, evenly arranged.

Red Belgic Rose.] Having greenish and red shoots and leaves, and fine double deep-red flowers.

Velvet Rose.] Grows three or four feet high, armed

armed with but few prickles; producing large velvet-red flowers, comprising semi-double, and double varieties, all very beautiful Roses.

Marbled Rose.] Grows four or five feet high, having brownish branches, with but few prickles; and large, double, finely-marbled, red-flowers.

Red and Yellow Austrian Rose.] Grows five or six feet high, having slender, reddish-branches, armed with short, brownish aculea; and with flowers of a reddish copper colour on one side, the other side yellow.

This is a curious variety, and the flowers assume a singularly agreeable appearance.

Yellow Austrian Rose.] Grows five or six feet high, having reddish very prickly shoots; and numerous bright-yellow flowers.

Double Yellow Rose.] Grows six or seven feet high; brownish branches, armed with numerous large and small yellowish prickles; and large very double yellow flowers.

Frankfort Rose.] Grows eight or ten feet high, is a vigorous shooter, with brownish branches, thinly armed with strong prickles; and produces largish, double, purplish-red flowers, that blow irregularly, and have but little fragrance.

All the above sorts are supposed to be varieties of the *Gallican Rose*; though it is probable some of them may also appear to belong to other species, particularly to the *Rosa Centifolia*, and *Rosa Alba*.

⁴*Rosa Centifolia.*

Hundred-leaved Red Rose, &c.] Grows from about three or four to six or eight feet high, in different sorts, all of them hispid and prickly; pinnated three and five-lobed leaves; and large very double red flowers, having very numerous petals, and of different shades in the varieties.

Specific description is,—Rose with hispid and prickly stalks and branches, inermous, or unarmed petioles; hispid pedunculi, and oval hispid germina.

Varieties are,

Common Dutch hundred-leaved Rose.] Grows three or four feet high, with erect greenish branches, but moderately armed with prickles; and large, remarkably double red-flower, with short regularly arranged petals.

Blush hundred-leaved Rose.] Grows like the other, with large, very double, pale-red flowers.

Provence Rose.] Grows five or six feet, with greenish-brown, prickly branches, and very large double globular red flowers, with large petals folding over one another, more or less in the varieties.

Varieties are.] Common Red Provence Rose,

and Pale Provence Rose; both of which having larger, and somewhat looser petals than the following sort. — Cabbage Provence Rose; having the petals closely folded over one another like cabbages — Dutch Cabbage Rose, very large, and cabbages tolerably — Childing Provence Rose — Great Royal Rose, grows six or eight feet high, producing remarkably large, somewhat loose, but very elegant flowers. — All these are large double red flowers, somewhat globular at first blowing, becoming gradually a little spreading at top, and are all very ornamental fragrant Roses.

Moss Provence Rose.] Supposed a variety of the common Provence; grows erectly, four or five feet high, having brownish stalks and branches, very closely armed with short prickles, and double, crimson-red flowers; having the calix and upper part of the peduncle surrounded with a rough mossy-like substance, effecting a curious singularity.

This a fine delicate Rose, of a high fragrance, which, together with its mossy calix, renders it of great estimation as a curiosity.

All the above varieties are supposed to belong to the species *Rosa Centifolia*, which however is not positively ascertained, as some of them sometimes nearly shew themselves varieties also of the *Rosa Gallica*, &c. However, they are all fine large double Roses, of very numerous petals, closely arranged, and in several sorts, closely folded over one another, particularly the common hundred-leaved Rose, and Provence kinds; but the Cabbage Provence most of all; the Common Provence, and Cabbage-Rose, are the most generally cultivated sorts in most gardens, as being very elegant Roses, as well as possess a remarkable fine fragrance: all the other varieties of this species have also a due share of merit as capital Roses, and will effect a delightful diversity in a collection.

From the great multiplicity of the petals of this species, &c. it derives the name *Centifolia*, or hundred-leaved Rose.

⁵*Rosa Cinnamomea.*

Cinnamon Rose.] Grows five or six feet high, or more, with purplish branches, thinly aculeated; pinnated five or seven-lobed leaves, having almost inermous petioles; smooth pedunculi, and smooth globular germina; and small purplish-red cinnamon-scented flowers, early in May.

Varieties.] With double flowers—single-flowered.

⁶*Rosa Alpina.*

Alpine inermous Rose.] Grows five or six feet

feet high, having smooth, or unarmed, reddish branches, pinnated seven-lobed smooth leaves, somewhat hispid pedunculi, oval germina, and deep-red single flowers; appearing in May.

This species, as being free from all kind of armature, common to the other sorts of Roses, is esteemed as a singularity; and from its inermous property, is often called the Virgin Rose.

⁷*Rosa Carolina.*

Carolina and Virginia Rose, &c.] Grows six or eight feet high, or more; having smooth, reddish branches, very thinly aculeated; pinnated, seven-lobed, smooth leaves, with prickly foot-stalks; somewhat hispid, pedunculi, globose hispid germen, and single red flowers, in clusters, appearing mostly in August and September.

Varieties.] Dwarf Pensylvanian Rose, with single and double red-flowers—American pale-red Rose.

This species and varieties grow naturally in different parts of North America; they effect a fine variety in our gardens, and are in estimation for their serotinous, or late-flowering property, as they often continue in blow from August until October; and the flowers are succeeded by numerous, red, berry-like hews in autumn, causing a variety all winter.

⁸*Rosa Villosa.*

Villose Apple-bearing Rose.] Grows six or eight feet high, having strong, erect, brownish, smooth branches; aculeated sparsely pinnated, seven-lobed, villose, or hairy-leaves, downy underneath, with prickly foot-stalks; hispid peduncles, globular, prickly germen; and large single red flowers, succeeded by large, round, prickly hews, as big as little apples.

This species merits admittance in every collection as a curiosity for the singularity of its fruit, both for variety and use; for it having a thick pulp of an agreeable acid relish, is often made into a tolerable good sweet-meat.

⁹*Rosa Pimpinellifolia.*

Burnet-leaved Rose.] Grows about a yard high, aculeated sparsely; small, neatly pinnated, seven-lobed leaves, having obtuse folioles, and rough petioles; smooth peduncles, globular, smooth germen; and small single flowers.

Varieties.] With red flowers — and with white flowers.

They grow wild in England, &c. and are cultivated in shrubberies for variety.

¹⁰*Rosa Spinossima.*

Most Spinous, Dwarf Burnet-leaved Rose, commonly called Scotch Rose.] Grows but two or three feet high, very closely armed with spines; small, neatly pinnated, seven-lobed leaves, with prickly foot-stalks; prickly pedunculi; oval, smooth germen; and numerous, small, single flowers, succeeded by round, dark-purple hews.

Varieties.] Common white-flowered — red-flowered — striped-flowered — marbled-flowered.

They grow naturally in England, and Scotland, &c. the first variety rises near a yard high, the others but one or two feet; all of which are single-flowered; but the flowers being numerous all over the branches, make a pretty appearance in a collection.

¹¹*Rosa Eglanteria.*

Eglantine Rose, or Sweet Briar.] Grows five or six feet high, having green branches, armed with strong spines sparsely; pinnated, seven-lobed, odoriferous leaves, with acute folioles, and rough foot-stalks; smooth pedunculi, globular smooth germina; and small pale-red flowers.

Varieties.] Common single-flowered — semi-double-flowered — double-flowered — blush double-flowered — yellow-flowered.

This species grows naturally in some parts of England, and in Switzerland.

It claims culture in every garden for the odoriferous property of its leaves; and should be planted in the borders, and other compartments contiguous to walks, or near the habitation, where the plants will impart their refreshing fragrance very profusely all around; and the young branches are excellent for improving the odour of nose-gays and bow-pots; and for which purpose the London gardeners raise great quantities for sale, of the common single kind, which they effect by seed, sowing it in autumn, in drills near an inch deep; and the plants may either remain, or be transplanted where required. See the *Propagation*.

But the double-flowered and yellow variety are continued the same, only by suckers and layers.

¹²*Rosa Moschata.*

Musk-Rose; supposed to be a Variety only of the Ever-green Musk-Rose.] Hath weak, smooth, green stalks and branches, rising by support, from six to eight or ten feet high, or more, thinly armed with strong spines; pinnated, seven-lobed, smooth leaves, with prickly foot-stalks; hispid peduncles; oval hispid germen;

and all the branches terminated by large umbellate clusters, of pure-white, musk-scented flowers in August, &c.

²³*Rosa Sempervirens.*

Sempervirent, or Ever-green Musk Rose.]

Hath somewhat trailing stalks and branches, rising by support five or six feet high, or more, having a smooth bark, armed with prickles; pinnated, five-lobed, smooth, shining, ever-green leaves, with prickly petioles; hispid pedunculi; oval hispid germen; and all the branches terminated by clusters of pure-white flower of a musky fragrance; appearing the end of July, and in August.

The sempervirent property of this elegant species, renders it a curiosity among the Rosy tribe; it also makes a fine appearance as a flowering shrub.

Variety.] Deciduous Musk-Rose, above-mentioned; supposed to be a variety of this species.

This species and variety flower in August; remarkable for producing them numerously in clusters, continuing in succession till October or November. They should generally be planted against some wall, or be allowed some support.

All the above thirteen species of *Rosa*, and their respective varieties, are of the shrub kind; all deciduous, except the last sort, and of hardy growth, succeed in any common soil and situation, and flower annually in great abundance from May till October, in different sorts; though the general flowering season for the principal part of them is June and July; but in a full collection of the different species, the blow is continued in constant succession several months, even sometimes from May till near Christmas; producing their flowers universally on the same years shoots, rising from those of the year before, generally on long pedunculi, each terminated by one or more Roses, which, in their characteristic state, consists each of five large petals, and many stamina; but in the doubles, the petals are very numerous; and in some sorts, the flowers are succeeded by fruit ripening to a red colour in autumn and winter; from the seed of which the plants may be raised; but the most certain and eligible mode of propagating most of the sorts is by suckers and layers; and by which methods they may be increased very expeditiously in great abundance. — See their *Propagation*.

All these shrubs are fine ornamental furniture for every garden, in the exceeding beauty

and fragrance of their elegant flowers; and as they will all grow any where without trouble, and may be obtained at all the nurseries, at moderate rates, every garden may be easily furnished with a full collection; and being possessed of a few of each sort, they will most of them soon encrease the stock considerably by suckers.

The season for planting all the sorts is, any time in open weather from October till March, and they will all flower in perfection the following summer; but if occasion requires they may be transplanted so late as any time in April, or even the beginning of May, which late planting is sometimes designedly practised to a few annually, to obtain a late bloom in autumn; however, the earlier the planting is performed, the stronger the plants will flower.

When these shrubs are designed for the shrubbery, and common flower borders, they should be planted singly; and may be trained with a single stem, one, two, or more feet high, and then encouraged to branch out into a bushy head; though when they are required to exhibit a more bushy growth, they are often suffered to branch away immediately from the bottom; as they will blow plentifully in any mode off training; however, I should advise keeping them to a single stem below, and let them form a bushy head upward. As to their culture, very little is required; which is only clearing the bottom from suckers, in winter, which will serve for new plants, and thin the head occasionally, when grown too thick and confused, and reduce any long rambling shoot, and cut out dead wood; but as these shrubs produce their flowers generally on the young shoots, some clip them down a little annually in autumn or winter, to force out a greater quantity of flowers, which however will probably be proportionally smaller; though those who want them for sale in the markets, &c. endeavour to procure as large a quantity as possible.

But where large quantities of the flowers are required particularly for sale, as is the case about London, the gardeners generally plant the shrubs in close rows, forming a sort of hedge, putting them in by *trench-planting*, a foot distance in the row; and in their culture keep them down to one, two, or three feet high, according to the sorts, by shearing or clipping them annually, in autumn or winter, at top and sides, in order to force out a greater quantity of laterals the following year for flowering, as before observed.

Some

Some plants of the best sorts may also be planted against a warm wall, to forward their shooting for an early bloom; a few of the Monthly Roses in particular, also the Provence kinds, and cinnamon Rose, &c. But as the Monthly Rose shoots early in the spring, as formerly hinted, it is always proper to have some plants of that sort against some warm fence, both for shelter, and to forward the bloom.

A few plants of the best sorts of Roses should also be potted to move occasionally to adorn any particular compartment.

Likewise, where there is convenience of forcing-frames, or hot-houses, &c. it is proper also to pot some prime sorts to force for an early spring bloom; for by aid of the above departments of artificial heat, Roses may be blowed almost any time in winter, or early in spring; for which purpose, having some plants of the Monthly Rose, common Provence, and Moss Provence, or any other choice sorts, in pots, which in winter, may be placed in any forcing-frames, worked either by dung, bark, or fire heat, or placed in a hot-house, they may be brought to flower in January, February, and March, and continued in succession till the plants in the natural ground begin to flower, by having different supplies of plants placed for forcing at two or three weeks interval. A quantity of plants should generally be potted for this use annually, and if they have a summer's growth in the pots, plunged in the ground, previous to the time of forcing, they will be more firmly rooted, so as to flower in greater perfection. See FORCING-FRAME.

Many of the gardeners about London erect forcing-frames, or glass-houses, with bark-pits on purpose for forcing Roses, as they are generally ready sale, at an early season, both the pots of plants in flower, and the Roses gathered as nosegays; and fetch an extraordinary great price, which pays sufficiently for forcing.

Method of Propagation.

The propagation of all the sorts is by suckers—layers—budding—and some sorts by seeds.—But suckers is the most common and expeditious method for propagating most of the species.

By Suckers.—Most of the sorts of Roses send up many suckers annually from the root, attaining from one or two to three or four feet height, or more, in one summer, and by these the shrubs may be expeditiously propagated in

great plenty; they may be taken up in autumn, winter, or early inspring, with some fibres to their bottom; and the strongest may be planted out finally, and the weakest in nursery lines for a year or two, or longer; they will readily grow, and will most of them produce flowers the following summer.

When these shrubs have grown into large bunches, with many suckers grown up to stems from the root, the whole may be taken up and slipped, or divided into so many separate plants, and planted out, as above.

Observe, that as the Moss Rose, Musk Rose, Apple-bearing Rose, and some others, furnish suckers but sparingly, so in default thereof must have recourse to layers, or budding; particularly for the Moss Provence.

By Layers.—All the sorts of these plants will grow by layers of the young shoots; and is an effectual method of propagation, for such sorts in particular, that sparingly furnish suckers, as the Moss Provence, &c. as aforesaid; and that to obtain plenty of shoots for laying, a quantity of the plants should be planted for stools; which being headed down low, they will throw out plenty of shoots near the ground in summer, for laying in autumn or winter following, by slit or twist-laying, they will be rooted by next autumn, and fit for transplantation, in nursery rows; though sometimes the Moss Rose, &c. require two years before they are tolerably well rooted; but of these sorts, you may also try layers of the young tender shoots of the year, layed in summer, any time in June, they will probably root a little the same season. However, the layers of all the sorts, after being properly rooted, should be taken up in autumn, and planted in the nursery, to have a one or two years growth, or to remain till wanted.

By Budding.—This is sometimes practised in propagating some choice sorts that seldom send up suckers, such as the Moss Provence, &c. as aforesaid; also, when intended to have two, three, or more different sorts of Roses upon the same tree, for curiosity; working them upon the Frankfort, or any other strong-shooting Rose stocks raised from suckers.

By Seeds.—This is sometimes practised to try to obtain new varieties; also sometimes for raising some particular permanent species, such as the Canine Rose, Burnet-leaved Rose, Scotch Rose, Apple-bearing Rose, single Sweet Briar, and such others as continue the same by seedlings; sowing them generally in au-

tumn soon after they are ripe, and they will sometimes rise the following spring ; as if not sowed till the spring season, most of the sorts are apt to remain till the second year before they rise freely ; sow them however, in any bed of light earth, either in shallow drills, or all over the surface, covering them half an inch deep ; and when the seedlings are a year old, transplant them in nursery-rows.

Observe however, that the double kinds, and other particular varieties of the species in general, cannot be continued the same with certainty by seeds, so must always be propagated by suckers or layers, &c.

But remark the common single Sweet Briar, when required in any considerable quantity, should generally be raised from seed, sowing it in drills half an inch deep, either to remain, or for transplantation ; though when designed to form a sort of hedge of this plant, to produce a crop of shoots to cut for the supply of markets during the summer, it is eligible to sow the seed at once in a drill where the plants are to stand.

ROSMARINUS, Rosemary.

It consists of one hardy shrubby ever-green, comprising some varieties, proper for the kitchen garden and shrubbery ; all of which are adorned with narrow stiff leaves, and numerous, small, monopetalous, ringent flowers, along the sides of the shoots.

Class and order, *Diandria Monogynia*.

Characters.] CALIX, is monophyllous, the mouth erect and bilabiated, the upper lip, being entire, the under one bifid.—COROLLA, is monopetalous, tubular below, and ringent above, having the upper lip short and bifid, and the under one reflexed and trifid, with the middle segment largest.—STAMINA, two subulate filaments, inclining towards the upper lip, and simple anthera.—PISTILLUM, a quadrifid germen ; a style like the stamina of the same length and situation, and a simple acute stigma.—PERICARPIUM none, four oval seeds lodged in the calix.

The species is,

ROSMARINUS *Officinalis*.

Common Officinal Rosemary.] Hath a shrubby stem branching numerously from the bottom upward, growing five or six feet high, closely garnished with linear stiff leaves ; and numerous small purplish flowers all along the upper part of the branches.

Varieties.] Common narrow-leaved Rosemary—broad-leaved—silver-striped-leaved—gold-striped-leaved.

All the varieties are tolerably hardy ever-greens, though the common green sorts are the hardiest ; the striped kinds are liable to suffer by hard frosts, if much exposed, or planted in wet ground, so should have a warm situation and dry soil ; some of these variegated kinds should also be potted, in order to have shelter of a green-house in winter. It should also be observed, that all the varieties of Rosemary should generally have a dry soil ; and if poor, sandy, gravelly, or rubbishy, they will be more durable than in moist, rich land ; in wet soils in particular, they are very liable to perish in winter. However, all the sorts will succeed in any common earth in a dry situation.

As to their uses in gardening, the common green sorts are employed as medical plants, &c. and both green and variegated kinds claim admittance in the shrubbery, to increase the variety in the ever-green collection, allowing them a dry soil, and the striped sorts in particular a warm situation, as above observed ; plant some of these sorts also against a warm fence, as a place of greater shelter to protect them in winter.

But it is proper always to keep a few plants of the striped sorts in pots, and place them in the green-house collection for winter shelter ; and where they will also effect a pretty variety.

The leaves and flowers of Rosemary are used in medicine.

Method of Propagation.

They are all easily propagated by slips or cuttings, and by layers.

By Slips and Cuttings.—In March or April, slip or cut off a quantity of young shoots, from about five or six to eight or ten inches long, and strip off the lower leaves ; then plant them in a border of light earth, in rows a foot asunder, and give a good watering, repeating it frequently till they are rooted, which they will effect in a short time, the same year, shoot at top, and become tolerable little plants by autumn, when about the beginning or middle of September, or in spring following, they may be transplanted where they are designed to remain.

By Layers.—In spring or autumn, lay down any of the convenient lower young branches in the earth, they will be well rooted by autumn following.

ROYENA, African Bladder Nut.

The plants are shrubby ever-green exotics for the green-house collection ; garnished with oval, and spear-shaped leaves ; and monopetalous.

nopetalous, five-parted reflexed flowers along the sides of the branches.

Class and order, *Decandria Digynia*.

Characters.] CALIX, is monophyllous, five-parted at top, and permanent.—COROLLA, is monopetalous, with a tube the length of the calix, and divided above into five-oval reflexed segments.—STAMINA, ten very short filaments, having oblong didymous erect antheræ.—PISTILLUM, an oval germen, two styles, and simple stigma.—PERICARPIUM, an oval quadrifid, and quadrivalved unilocular capsule, having four oblong triangular nuts.

The species are,

¹ROYENA *lucida*.

Lucid African Bladder Nuts.] Hath a shrubby upright stem, branching eight or ten feet high; oval, somewhat rough but shining green leaves, alternately; and white flowers at the sides of the branches.

²ROYENA *Glabra*.

Glabrous African Bladder Nut.] Hath a shrubby upright stem, branching five or six feet high; small, lanceolate, smooth leaves; and small white flowers at the sides of the branches.

³ROYENA *Hirsuta*.

Hairy African Bladder Nut.] Hath a shrubby upright stem, branching alternately, six or seven feet high, lanceolate hairy leaves; and purplish flowers at the sides of the branches.

These three shrubs being natives of the Cape of Good Hope, require shelter here in winter, so must always be kept in pots, and placed among the green-house plants; where they will form a good variety, as ever-greens; and will flower in July or August; but the flowers are small, and of but little beauty, succeeded sometimes by ripe capsules, particularly the first and second sorts; their culture is the same as other shrubby green-house plants.

They are propagated by seed, layers, and cuttings.

By Seed.—Sow it in spring, in pots, and plunge them in a bark-bed, or other hot-bed; and when the plants are three or four inches high, pot them off separately.

By Layers.—Lay the young shoots of the year in summer, as they are unapt to strike in the older wood.

By Cuttings.—In spring, plant some young shoots in pots, and plunge them in a hot-bed.

RUBIA, Madder.

This genus consists of two hardy herbaceous

perennials, valuable for their roots, as a most useful commodity in dying red; they having thick succulent roots; long, thick procumbent stalks; spear-shaped radiant leaves; and campanulate, four-parted, yellow flowers, in spikes at the ends of the branches.

Class and order, *Tetrandria Monogynia*.

Characters.] CALIX, is small, placed on the germen, and four-parted.—COROLLA, is monopetalous, bell-shaped, and four-parted at top.—STAMINA, four awl-shaped, short filaments, having simple anthera.—PISTILLUM, a didymous germen under the calix; slender style bifid at top, and headed stigmas.—PERICARPIUM, two smooth berries joined together; each having one roundish umbilicated seed.

The species are,

¹RUBIA *Tinctorum*.

Common Dying Madder.] Hath a long, thick, fibrated, fleshy, reddish root, sending up large four-cornered, jointed, procumbent stalks, five or six feet long, branching by pairs, crossing alternately; garnished at each joint with six spear-shaped leaves in a verticillus, or radius; and small yellow flowers, collected in loose spikes at the sides and ends of the branches.

It is a native of Italy, and about Montpellier in France, but grows freely here in the open ground.

²RUBIA *Peregrina*.

Wild quaternate-leaved Madder.] Hath thickish, fibrated, spreading roots; slender, four-cornered, procumbent, branchy stalks; garnished at each joint with quaternate, short, rough leaves, and clusters of yellow flowers.

This sort is supposed to be a native of England, as it is not known to grow naturally in any other part of the world.

Both these species of Madder are herbaceous, of hardy growth; perennial in root, send up stalks in spring, and flower in June and July, succeeded by seeds in autumn; but those of the *Rubia Tinctorum*, do not always ripen in England; it however multiplies exceedingly by suckers for propagation.

These plants are sometimes cultivated in gardens, in any open compartments, for variety.

But the chief merit of the plants is in their roots, to use for dying red, &c. And are also used in medicine, which taken inwardly, tinges the urine of a deep-red colour; but the *Rubia Tinctorum* in particular, is in greatest estimation for the dyer's purpose. And is cultivated

tivated in great quantities in fields abroad, in Holland, &c. for the roots aforesaid, as a very valuable commodity both for dyers and calico-printers; being propagated generally by suckers, or off-sets, which are taken off in the spring, and planted in a light deep soil, in rows two feet asunder, and require two or three years growth for the roots to attain perfection. They are also cultivated in some parts of England for profit, as they are hardy enough, and increase abundantly by off-sets or suckers from the root, and are sometimes raised in tolerable perfection. However, as in some parts, after repeated experiments in its cultivation, the crops have no ways answered the purpose, occasioned probably by the soil not being suitable, or not properly planted and managed; therefore, at the first trial, it is adviseable to plant only a small quantity in different situations; and by observing the soil and method of culture of those which succeeds best, it may a direction to the culture of larger quantities; and where crops of it succeed, it proves a very saleable article, and pays exceedingly well for its cultivation; and the roots may either be sold to the dyers, or druggists, or those who prepare them for use; though abroad the great Madder planters erect stoves and kilns for drying it; and stamping-mills for reducing it to powder, to render it more portable to send to distant countries; but the roots for home consumption may also be used fresh for dying; first washing them clean, then cut to pieces, and pounded in a mortar, and then put into the cauldron, or dying copper.

Their Propagation and Culture.

They are propagated by off-sets or suckers, arising from the roots of old plants in the spring; and should be slipped off soon after they appear above ground; at which time, opening the earth round the roots, slip off the side-suckers with as much root part and fibres to each as possible, preserving the tops entire; which should be planted directly as advised below.

The season for taking off the suckers and planting them is about the beginning, middle, or end of April, or beginning of May, when they appear above ground.

Observe, these plants delight in a light, rich, deep soil, or a light, deep, pliable, loamy land; and rather a somewhat low than high situation; which should be deeply digged or ploughed in autumn, or winter; laying it in rough ridges to mellow and pulverize by the weather; and in spring levelled down for the

reception of the plants; but for large quantities in fields, the ground should be ploughed cross-ways again, once or twice in the spring, and well harrowed.

Then in April, or early in May, provide a proper quantity of sets, or suckers, as aforesaid; and with a dibble plant them in rows two feet asunder, and one distant in the row, putting each plant low enough in proportion to the length of its root, leaving most of the green top out of the ground, and close the earth well about each set, as you go on: thus they will soon take root, and shoot at top. But some set these plants in beds, three rows length-ways, at two feet distance, with wide alleys between bed and bed, in order for landing up the crown of the roots two or three inches deep, in winter.

In either mode of planting, they will shoot up into stalks the same year; but the roots will require two or three years growth before they are large enough for use; during which period, observe the following culture.

Keep them clean from weeds all the summer by broad-hoeing, in dry weather; and in autumn, when the stalks decay, cut them down, then slightly dig the ground between the rows, raising it somewhat ridge-ways along the rows of plants, an inch or two thick over their crowns; or if they are in beds, they may be landed up from the alleys the above depth. Next spring the roots will shoot up again stronger than before, and will soon cover the ground, and keep down weeds; in autumn following, the decayed haulm must be again cut down, and all weeds cleared away, slightly dig the ground, &c. as in the former year; and next spring the plants will still rise stronger, and the roots continue encreasing in size; so as by the following October, having had three summers growth, they will be fit to take up for use.

The method of taking up the Madder-roots is by trenching the ground the way of the rows; beginning at one end of the ground, and open a two-feet wide trench close along by the first row of plants, digging down to the depth of the roots to get them clean out to the bottom; then opening another trench close to the next row, turning the earth thereof into the first; and so proceed trench and trench till the whole is taken up.

The Madder-roots thus taken up for use, are sometimes used fresh for dying, preparing them by washing, and pounding them as before observed. But commonly when designed for

for keeping, or to be sent to a distance, are dried in some covered airy shed, then all mould being rubbed off, and the roots sufficiently dry, they may then be sold to those who manufacture them for use, if not performed by the cultivator; which consists of kiln drying them, or drying them in some stove-house, &c. then threshed to beat off the outer skin, in order to separate it from the inner part of the root, as being of inferior quality. The roots being then dried in a kiln about twenty-four hours, are removed to a mill, or pounding-house, where they are pounded in a long hollow oaken block, with stampers kept in motion by the mill; and when thus reduced to powder, is sifted and put up in casks for use.

But in Holland, where great quantities of this plant is cultivated, they have public kilns, mills, &c. where the cultivators send the roots to be manufactured. And there are treatises to be had here, exhibiting the kilns, mills, and other necessary accommodations for manufacturing this valuable material; together with full directions in the management thereof.

RUBUS, Bramble, or Raspberry-bush.

Consists of under-shrubby and herbaceous perennials, valuable, some as fruit-bearing plants, and others for variety in the pleasure ground, particularly the shrubby kinds; some being of erect growth, others long trailers, garnished with pinnated, ternate, and palmated leaves, in different species; and pentapetalous, icofandrous flowers.

Class and order, *Icofandria Polygynia*.

Characters.] CALIX, is monophyllous, five-parted and permanent. — COROLLA, five-roundish erecto-patent petals. — STAMINA, twenty or more short filaments, having roundish compressed antheræ. — PISTILLUM, numerous germina, many capillary styles from the sides of the germens, crowned with permanent stigmas. — PERICARPIUM, a compound berry, composed of many roundish unilocular acini, each having one oblong seed.

There are about thirteen species, nine or ten of which are ligneous and shrubby; the others are somewhat herbaceous; but the most material sorts are principally of the ligneous, or shrubby kind, and of which about five or six of the most noted species are cultivated in our gardens; the first of which *Rubus Idæus*, or Raspberry-plant, is chiefly valued for its fruit; and the other sorts as furniture for the shrubbery, &c. They are all deciduous plants of hardy growth, that succeed in any common

soil and situation; and consists of upright ligneous kinds, trailing shrubby kinds, and herbaceous kinds.

Upright ligneous Kind.

Under this head is comprised the common Raspberry-plant, and varieties; and other Raspberry kinds. All of which rising with several upright ligneous, or under-shrubby stems, from about three or four to six or seven feet high.

RUBUS Idæus.

Common Raspberry Bush.] Rises with several upright, straight, ligneous, pithy stems from the root; four or five feet high, closely armed with short prickles; pinnated, three and five-lobed rough leaves; and at the axillas and ends of the lateral shoots, small clusters of purplish and white flowers, succeeded by ripe berries in July.

Varieties.] Common red Raspberry — white-fruited Raspberry — twice-bearing red, and white Raspberry, producing the first crop of fruit in July, and the second in September; and is esteemed a curiosity — smooth Raspberry, the stalks, &c. being devoid of armature.

The common red sort grows wild in woods in England, but has been greatly improved by garden culture.

All the varieties bear plentifully, particularly the first three; they being all propagated by suckers, planted in any open situation, in rows four or five feet asunder, and a yard distant in the rows, being planted in autumn, winter, or spring, they bear the summer following. Their mode of bearing is upon the year-old wood; that is, a supply of shoots rising annually from the root; which, when a year old send out many small laterals, and upon these the fruit is produced the same year; remarking the same individual shoots never bear but once; a succession of young shoots or stems being sent up annually from the root every summer for bearing; those produced one year, bear the fruit the next, and then totally decay to the root, in winter following, they never surviving to bear a second year, but are always succeeded by a plentiful supply that have arisen from the bottom in summer for next year's bearing; so that every winter, all the decayed stalks that bore the fruit the preceding summer, must be broken down close to the ground; they being readily distinguished from the young succession wood, which at the same time must be regularly thinned to four or five of the strongest shoots.

shoots on each root ; and these should be topped to about a yard in height, or a little more or less, according to their strength, and they will all branch out laterally the following spring ; and upon the laterals the flowers and fruit are produced. — See the *Propagation and general Culture*.

The Raspberry is in estimation both as eatable fruit, and for many culinary purposes, as for tarts, fauces, &c. when ripe.

²RUBUS *Odorata*.

Odoriferous Virginia flowering Raspberry.] Rises with many upright, large, under-shrubby, brown, inermous stems, from the bottom, five or six feet high ; very large simple palmated leaves ; and the shoots terminated by many large purplish flowers, succeeded by small red fruit ; rarely ripening in England.

This plant is very ornamental, having beautiful large foliage, and numerous large flowers ; continuing near two months, which renders it worthy of admittance in every shrubbery plantation ; where it will multiply exceedingly by suckers sent up annually from the root all around.

³RUBUS *Occidentalis*.

Occidental, or Canada Black-fruited Raspberry.] Rises with erect, ligneous, prickly, purplish stems four or five feet high ; ternate leaves, hoary underneath, having taper foot-stalks ; and the shoots terminated by clusters of small flowers, succeeded by small black fruit.

Trailing Shrubby Kinds.

Consists of the common Bramble, and varieties ; and some others of the Bramble kind, being mostly shrubby trailers, of hardy growth, and deciduous.

⁴RUBUS *Fruticosus*.

Shrubby Rubus, or common Bramble of the Hedges.] Hath very long, shrubby, trailing, channelled, greenish, and reddish stalks, closely armed with strong crooked aculi ; digitated, five and three-lobed leaves, having prickly petioles ; and all the lateral shoots terminated by clusters of white flowers, succeeded by ripe black-berries in autumn.

Varieties.] Common Bramble, or Blackberry plant of the hedges—double blossomed Bramble of the gardens—white-fruited Bramble—inermous, or thornless Bramble—cut-leaved Bramble—striped-leaved Bramble.

All these varieties are of trailing growth, with very long, luxuriant, durable shoots. The common wild bramble, or Blackberry plant,

being the parent species, which grows wild on banks, and in field-hedges, almost everywhere ; so is seldom admitted in gardens, except a plant or two for variety among the climbing-tribe, or where wilds or thickets are intended. But the double-blossomed Bramble, white-berried, and thornless kind, &c. being curiosities, they claim admittance in every shrubbery ; and may be trained both as climbers, allowing them support of bushes or stakes ; or may be trained as standard shrubs, if staked, and trimmed down at top, to cause them to shoot out into bushy heads, continuing to reduce the rambling shoots as occasion requires, to keep the head to the desired form ; and where any part of a garden is designed to represent wilds, &c. some plants of all the varieties should be introduced, and suffered to shoot and run according to the course of nature.

⁵RUBUS *Cæsius*.

Blue-berried Bramble, or Dewberry-bush.] Hath long, taper, slender, trailing, prickly-stalks ; ternate, almost naked leaves ; and whitish flowers at the sides and ends of the branches, succeeded by large sky-blue fruit in autumn.

It grows naturally in moist situations in England ; and is sometimes admitted into gardens for variety.

⁶RUBUS *Hispidus*.

Hispid Canada Bramble.] Hath long, ligneous, procumbent, hispid stalks ; ternate, naked, cut, serrated leaves, with hispid foot-stalks.

Herbaceous Perennial Kinds.

Comprises two dwarfish, somewhat herbaceous, durable plants of erect growth, rising but a few inches high.

⁷RUBUS *Chamæmorus*.

Chamæmorus Dwarf Mulberry, or Cloud-berry.] Rises with slender inermous stalks, six or eight inches high ; garnished with two simple, lobated leaves ; and the stalks terminated by one purple flower, succeeded by a small black fruit, resembling a mulberry.

It grows naturally in England and Scotland, &c. in high moorish situations.

⁸RUBUS *Arcticus*.

Northern Rubus, or Dwarf Siberian Bramble.] Rises with erect inermous stalks, but three or four inches high ; ternate leaves, and the stalks terminated by purple flowers, singly ; succeeded by small red fruit, having the smell and taste of strawberries.

All

All the above eight species of *Rubus*, are for the general part deciduous, the leaves coming out in the spring, and fall off in the winter; and they flower generally in June and July. The flowers are composed each of five roundish petals and numerous stamina, succeeded by roundish compound berries, each being composed of many small acini of a pulpy juicy nature;—ripening from July till October, in different sorts: remarking those of the *Rubus Idæus* and varieties, are the principal sorts for general use.

The plants of all the species are very hardy; the ligneous and shrubby kinds in particular, will prosper almost any where. But the herbaceous kinds, being naturally residents of moorish or fenny places, require some similar situations when cultivated in gardens.

With respect to the merit of all the sorts as garden plants; observe as follows.

The first species: *Common Raspberry*, and varieties, demand culture in every garden for their fruit; particularly the common red kind, white sort, and twice-bearing raspberry; all of which are great bearers: but for the general plantations, chuse principally the common red and the white kind, as being generally the greatest bearers of all. Planting also a share of the twice-bearing sort, both as a curiosity, and for the sake of its autumnal crops of fruit, which in favourable seasons, ripen in tolerable perfection; observing to allow all the sorts some open exposure in the kitchen-garden, though they will prosper in almost any situation. It is however adviseable to plant the general plantations mostly in a free exposure in rows, a yard and half asunder: some plants may also be disposed singly about the borders or shrubbery clumps, for variety: and, in all the modes of planting, they should generally be kept to single bunches of four or five stems on each root or stock. See their *Propagation and general Culture*.

The other seven species, are considered as plants of variety, for hardy plantations in the shrubbery: some of which are also very ornamental flowering plants; particularly the Virginian flowering Raspberry, and the double blossomed Bramble; both of which, having great merit as furniture for ornamental compartments: and the white-berried Bramble is a great curiosity. All the other species and varieties serve to diversify large collections.

Propagation and Culture of the common Raspberry and Varieties.

The propagation of the common Raspberry and varieties, is expeditiously effected by suckers from the root; all the sorts sending up great numbers on all sides annually growing from three to four or five feet height the same year, and form proper plants by autumn or winter following, for transplanting for new plantations, and will all bear fruit the following summer.

Therefore, any time from October till March, in open weather, having recourse to some good plantation of Raspberry plants of some standing; and proceed to take up a sufficient quantity of last summer's suckers, that are situated around the outside of the stools, or main stock, raising them carefully with plenty of fibres; and, having obtained a proper quantity, then let them be trimmed for planting, shortening any long straggling roots, and, if any naked woody parts of the root of the old stool adhere, cut it off; observing at the same time, if one or more buds appear near the root, they being the embryo of future shoots, must be very carefully preserved: and shorten each sucker at top, to about two or three feet long, or more according to their strength, they are then ready for planting: having previous to this, chosen an open spot of good ground, as before advised; and having well dunged and trenched it one or two spades deep, proceed to put in the plants above prepared, as soon as possible.

With a line mark out the distances for the plants, in rows, a yard and half distance, and a yard asunder in the rows, which is considerably more than is commonly allowed: but, if planted much closer, the plants, as they send up numerous suckers in summer, would grow so close, as to form quite a thicket, so as to exclude the due influence of sun and air from the fruit, as well as to render it troublesome to get between the rows, occasionally to gather the produce; therefore allow the above distances: and having drawn lines accordingly, proceed with a spade, and open small apertures in the ground, close along the line, one for each plant, a yard asunder, planting them as you go on, one in each hole erectly, covering in the roots properly with the earth, treading it moderately firm, to preserve the upright position of the plants: observing, if the planting is performed late in the spring, it is adviseable to give a good watering

watering, and repeat it occasionally, till the plants have struck fresh root.

Having thus made a plantation of Raspberries, they will readily take root, and set to growing freely in the spring, they being naturally of a free growth, and most of them will bear tolerably the first summer; but in the second they will bear a full crop in the utmost perfection.

As to their general culture, it consists of the following operations — Keeping them clean from weeds all summer by broad-hoeing; giving them an annual dressing in autumn or winter, consisting of breaking down the decayed stems that bore the preceding summer; thinning the young succession bearers; clearing away all intermediate suckers between those of the main stocks, and then dig the ground between the rows of plants; observing the following particulars of the method of performing the operations of their annual dressing.

Previous to the above-mentioned annual dressing of Raspberries, observe, as we before noticed of their mode of bearing, that as they produce a fresh supply of shoots or suckers every year from the bottom for bearing, those produced one year, bear the next, then totally decay to the root in winter, there being at the same time a succession of last summer's shoots; on the same stools, for bearing the summer following: therefore, in the annual dressing, which may be performed any time from October till March, first proceed to clear out all the decayed stems, being last summer's bearers, breaking them down close to the bottom; then examine the supply of young shoots for next year's bearing, selecting three or four, but not more than five or six of the strongest on each stool, cutting all the others away close to the ground: likewise draw up all straggling suckers between the main plants; all of which remaining plants, should be shortened according to their strength, cutting them generally a little below the bend at top of the shoots, to about three or four feet in length, both to render them more robust, to support themselves more firmly upright in summer, and to promote a stronger supply of laterals for flowering and fruiting. Or if you should chuse to leave them longer, or at full length, those of each stock may be plaited together, in order to support each other erect: then having cleared away all the rubbish, let the ground between the rows be neatly dug one spade deep. As you

proceed in digging, clear out all the roots of straggling suckers between the rows, &c. leaving the earth close and level about and between all the plants: thus far is the whole necessary culture of a plantation of Raspberries, which must always be repeated annually, at the seasons abovementioned.

Allow them a little manure of rotten dung once every other year, applying it in the winter dressing and dig it in one spade deep; it will add vigour to the plants, so as to continue them producing fruit in great perfection several years.

However, it is adviseable to make a fresh plantation every four or five years, in a fresh spot of ground, as after that period of time, the plants, although they may continue shooting with tolerable vigour, yet they are apt to be less fruitful, and the fruit smaller than in younger plantations in a fresh prepared piece of ground.

Propagation, &c. of the other Species.

The propagation of the other species of Raspberries, Bramble, &c. is by suckers, layers, cuttings, dividing the roots, &c. and the two herbaceous kinds also by seed.

By Suckers. — All the Raspberry kinds in particular send up many suckers annually, and by which they may be propagated in great abundance, taking them up in autumn, winter, or spring, with roots, and the strongest may be planted at once in the shrubbery, and the others in nursery rows for a year or two, or till wanted.

By Layers. — All the Bramble kind are easily propagated by this method, laying the shoots almost any time, they will readily emit roots at every joint, and be fit to transplant in autumn following.

By Cuttings. — By this method also may the Brambles be propagated in autumn; cutting off some of the younger shoots, and divide them into lengths a foot long, and plant them in a shady border, many of them will strike.

By dividing the Roots. — Any of the Raspberry kind, &c. and the herbaceous species, when encreased into large bunches, may be divided or slipped into several distinct sets, and plant them separately.

By Seed. — As the two herbaceous species do not always encrease freely by roots in gardens, therefore, in default of which, procure some of the ripe fruit in autumn, or as soon as possible; and chusing some moist situation, either

either in a nursery, or where you design the plants to remain, sow the seed half an inch deep; observing, if some of the plants are permitted to remain where raised, they will probably be more prosperous than such as are transplanted.

RUDBECKIA, Dwarf American Sunflower.

This genus comprehends several herbaceous flowery perennials, and a biennial, serving to embellish the pleasure ground; rising with annual stalks, from about half a yard to six or eight feet high, garnished with oval, spear-shaped, and divided leaves; and the stalks terminated by large compound radiated flowers.

Class and order, *Syngenesia Polygamia Frustanea*.

Characters.] **CALIX**, a general calix, composed of two orders of broad, plane, short, scaly leaves, containing many florets.—**COROLLA**, is compound, and radiated; consisting of many tubular, hermaphrodite florets in the disc, and spear-shaped, flat, barren florets in the radius.—**STAMINA**, five very short hair-like filaments, having cylindric antheræ.—**PISTILLUM**, a tetragonous germen, filiforme style, and bipartite revolute stigma.—**PERICARPIUM**, none; the hermaphrodite florets, succeed each to one oblong seed, crowned with down, which is quadridentate, and the seeds lodged in a conic chaffy receptacle.

There are six species, five of them herbaceous perennials, and the sixth a biennial, all natives of North America; but grow freely here in our gardens, in any open compartments.

Perennial Kinds.

¹**RUDBECKIA Hirta.**

Hairy Dwarf American Sunflower.] Rises with upright stalks, a foot and half high; oval-spattle-shaped, undivided, triple-nerved leaves; and the stems dividing upward into many long pedunculi, terminated each by one large radiated yellow flower, having a prominent purple disc, and the petals of the radius emarginated.

²**RUDBECKIA Purpurea.**

Purple Dwarf Carolina Sunflower.] Rises with upright stalks about two feet high; oval-lanceolate, undivided, alternate leaves; and the stalks and branches terminated by purple flowers, singly; having the petals of the radius bifid.

Varieties.] With a dark-purple disc, and

pale red radius—with long purple petals in the radius—with broad petals in the radius.

³**RUDBECKIA Laciniata.**

Lacinated, or jagged-leaved Tall Virginian Rudbeckia.] Rises with upright stems, six or eight feet high; large, compound, mostly, five-lobed leaves, having the lobes deeply lacinated, or jagged; and the stems and branches terminated by radiated yellow flowers.

Varieties.] Broad-leaved—narrow leaved—purple-stalked, with digitated leaves, &c.

⁴**RUDBECKIA Angustifolia.**

Narrow-leaved Dwarf Virginia Sunflower.] Rises with upright firm stems, two or three feet high, or more; long, linear, or very narrow, entire, opposite leaves; and the stalks terminated by yellow-rayed flowers, having a dark-red disc.

⁵**RUDBECKIA Oppositifolia.**

Opposite-leaved Dwarf Virginia Sunflower.] Rises with upright stalks two or three feet high; lanceolate-oval, serrated, opposite leaves, and wholly yellow flowers, having the petals of the radius bifid.

Biennial Kind.

⁶**RUBBECKIA Triloba.**

Three-lobed Virginia Rudbeckia.] Hath spatula shaped, trilobated, radical leaves; amidst them upright stems, garnished also with three-lobed leaves; but those on the branches are undivided; and yellow-rayed flowers, having dark-purple discs.

All these six species flower here annually in July and August, often continuing in succession till September or October; and in some sorts, are sometimes succeeded by ripe seeds in autumn, particularly the first and last species.

They are all tolerably hardy: the first five species are mostly perennial in root, but annual in stalk; though the fourth and fifth sorts have often a tendency to a biennial nature; however, the sixth sort is perfectly biennial; all of which send up their flower-stems in the spring, which generally branch out upward, the branches terminated by long pedunculi, each crowned by one moderately-large radiated flower, nearly resembling the common sunflower, but smaller; have generally a prominent, somewhat pyramidal disc, and a spreading radius; and are all very conspicuous, even at a distance.

All the species are proper furniture for the open compartments of the pleasure-ground, as being very showy plants when in bloom; and produce many flowers in succession, two or

three months ; effecting a good ornamental appearance.

Observe to allow most of the sorts a lightish, dry soil, and somewhat sheltered situation ; remarking however, the third sort in particular (*Rudbeckia laciniata*) will succeed almost any where.

Method of Propagation, &c.

Their propagation is by off-sets, and parting the roots ; and by seeds.

By off-sets, and parting the roots.—This is practicable for all the perennial kinds ; but the first sort in particular generally resolves itself into several off-set heads, at the crown of the root, which being slipped in autumn, or early in spring, each will form a proper plant. Most of the other perennial sorts encrease by the root, though the *Rudbeckia Purpurea* multiply rather more sparingly than the others ; however, the propagation of all the sorts may be effected less or more by parting the roots in autumn, when the stalks decay.

Observe, as some of the perennial kinds sometimes discover a tendency to go off in three or four years, it is eligible to continue propagating them frequently to keep up a stock of vigorous plants. Some sorts being also sometimes inclinable to a biennial nature, are apt to decay soon after they have flowered, without encreasing at root, for future propagation, particularly the fourth and fifth sorts ; to prevent which, it is proper to cut down some of the flower-stems of such kinds in May, or early in June, which will encourage their multiplying more effectually by root off-sets, fit for slipping next autumn.

By Seed.—All the sorts may be raised plentifully from seed ; but the biennial sorts in particular must always be raised from seed annually ; likewise, such of perennials as are biennially inclined ; sowing the seeds in April, in a border of light earth, and rake them in ; and when the plants are two or three inches high, prick them out in nursery-rows, till autumn ; then transplanted where they are finally to remain.

RUMEX, Dock ; comprehending the *Acetosa*, or Sorrel, &c.

This genus furnishes herbaceous perennials for the kitchen-garden, and pleasure-ground, and a ligneous ever-green for the green-house ; are garnished with simple, oblong, saggitated, and roundish, heart-shaped leaves ; and spikes of small tripetalous flowers of no beauty.

Class and order, *Hexandria Trigynia*.

Characters.] CALIX, three obtuse, reflexed, permanent leaves.—COROLLA, three small oval, connivent, permanent petals, like the leaves of the calix, but larger.—STAMINA, six very short capillary filaments, having erect didymous antheræ.—PISTILLUM, a turbittated triquetrous germen, three hair-like reflexed styles, and large laciniated stigmas.—PERICARPIUM, none ; a single triquetrous seed, lodged in the permanent corolla.

To this genus, *Rumex*, is added the *Acetosa*, or Sorrel, formerly considered as a distinct genus ; consisting of several species, but now all ranged as species of *Rumex*, which comprehends in the whole about twenty-six herbaceous, and one woody species ; eight or ten of the former grow wild in this country, and the others are of foreign growth ; but there are not more than four or five that have merit for garden culture ; consisting of four hardy herbaceous perennials, and one tender woody plant.

Hardy Herbaceous Kinds.

Under this head is comprised the common culinary Sorrels for the kitchen-garden ; the Patience Dock, &c. and Bloody Dock, for medical purposes, and variety ; all of which are hardy perennials.

The two first sorts are of the Sorrel kind.

¹RUMEX *Acetosa*.

Acetosa, or common Arrow-pointed Meadow Sorrel.] Hath fibrated roots, crowned by a large tuft of oblong-saggitated leaves ; and amongst them upright stems a foot or more high, terminated by spikes of small herbaceous dioecious flowers, succeeded by ripe seeds in autumn.

Varieties.] Common Meadow-sorrel.—Barren Northern Sorrel, which rarely running to seed continues almost always in leaf for use—broad-leaved Mountain Sorrel.

The Common Sorrel is a natural resident of our meadows and pastures ; but has been long admitted an inhabitant of the gardens as a soup-herb ; and is the most commonly cultivated Sorrel for general use, both as a valuable acid culinary herb, and for medicinal purposes ; its leaves being the useful part, which by garden culture obtain a fine large size.

The plants are easily raised from seed, and by parting the roots. See their *Propagation*, &c.

²RUMEX *Scutatus*.

Shield-shaped Rumex, Round-leaved, or French Sorrel.] Hath a creeping root crowned with

with a tuft of large roundish, heart-shaped, hastated leaves; rambling shoots, and the flower stems terminated by spikes of small hermaphrodite flowers, succeeded by seeds in autumn.

This species of Sorrel is by many preferred to the common *Acetosa*, or Meadow Sorrel; the leaves being larger, and thought to possess a more agreeable acid relish.

The above two species of Sorrel and varieties are all of the culinary kind; any, or all of which may be raised for general use; and may all, but the Barren Sorrel, be propagated by seed: all the sorts also by parting the roots, planting them in any bed or border, ten or twelve inches asunder, and they will furnish leaves most part of the year.

³*RUMEX Patientia.*

Patientia, or *Patience Dock*, or *Monks Rhubarb*.] Hath a large, thick, divided, deeply-striking root, yellow within, crowned with large, oblong, heart-shaped leaves, a foot long, on very thick reddish foot-stalks; upright strong stems, dividing and branching three or four feet high; having the branches terminated by close erect spikes of whitish hermaphrodite flowers, and with entire valves, one being graniferous.

Variety.] Round-leaved Alpine Patience Dock; commonly called Monks Rhubarb.

This species and variety are natives of Italy and the Alps; are retained in our gardens both as medical plants, and to effect variety, also formerly for culinary uses; they shoot up into stalks annually in the spring, flower in May, and ripen seeds in autumn.

⁴*RUMEX Sanguineus.*

Bloody Dock.] Hath long downright roots, erect red-stalks, two or three feet high; heart-formed lanceolate leaves, having blood-red veins, and many red spots; the stalks terminated by spikes of hermaphrodite flowers, and with entire valves, one being graniferous.

This is retained in many gardens for the sake of variety.

Woody Kind for the Green-house.

⁵*RUMEX Lunaria.*

Tree-like Rumex, commonly called *Tree Sorrel*.] Rises with a woody, tree-like, smooth stem, branching eight or ten feet high; garnished with roundish heart-shaped leaves; the branches terminated by loose panicles of greenish hermaphrodite flowers, and with smooth valves.

This is an exotic from the Canary Islands,

and is retained in our gardens to encrease the variety in the green-house collection.

The above five species are principally all the sorts of *Rumex*, commonly cultivated in the English gardens; the four herbaceous kinds are perennial in root, and annual in stalks, and hardy enough to succeed in any open situation; and the woody-kind is durable both in root and stem, &c. and is tender, requiring shelter of a green-house, in winter. They flower generally in June or July; the flowers are small and tripetalous, generally terminating the stalks and branches in spikes, but are not ornamental; and are succeeded by ripe seeds in autumn.

Their merit as garden plants is, all the herbaceous Sorrel kinds, are eminent soup-herbs for culture in the kitchen-garden, as aforesaid: the *Rumex Patientia*, as a medical plant; also, together with the *Rumex Sanguineus*, is often employed for variety in the pleasure-ground; and the *Tree Sorrel* being tender, must be potted and placed among the green-house exotics.

Propagation and Culture.

Most of the herbaceous culinary Sorrels are raised from seed, and by parting the roots.

By Seed. — The common Sorrel, and round-leaved kind may be raised abundantly by seed in the spring; but the common Sorrel in particular should be generally raised by this method, as the other propagates exceedingly by its repent roots, &c. However, both sorts may be sowed in March, in any bed or border, broad-cast, and rake them in evenly, they will soon come up; observing, if the plants rise too thick, thin them moderately; and after being a little advanced in growth in summer, plant out a quantity of the stoutest in moist weather, in some bed or border in rows, the common sort and varieties about eight or nine inches asunder, and the other a foot at least, giving proper waterings, and they will grow freely, and be fit to cut for use the same summer and autumn, &c. and continue several years.

Observe however, of the common Sorrel in particular, that as seedling plants of one or two years old, generally produce larger leaves than older plants, it may be eligible to raise a fresh supply of seedlings annually, or at least every other year.

By parting the Roots. — All the sorts may be propagated by this method, but the Round-leaved French Sorrel in particular increases exceedingly by running at the root; and the Barren

Barren Sorrel, rarely producing seed, is propagated principally only by parting the roots. However, any of the sorts may be easily increased by this method, which may be effected either in autumn or spring, though I should rather prefer the spring season, about the beginning or middle of March; either slipping off a quantity of off sets from the old plants as they stand, by assistance of a knife or spade; or take some of them wholly up, and divide them into several slips, planting them in rows a foot distance, and give directly a good watering, they will expeditiously take root, assume a free growth, and furnish plenty of leaves for use all summer and autumn, &c.

As to the culture of these plants, very little is required more than the necessary care of keeping them clean from weeds; and in summer, when they run to stalk, it is proper to cut them down close to encourage a more plentiful supply of large leaves from the bottom; likewise, when the leaves have become very rank, cut them down occasionally towards the latter part of summer, that the roots may send up a good supply of fresh leaves for autumn, and winter service.

The *Patientia* and Bloody Dock, are also raised by seed, and the former likewise by roots.

By Seed.—In autumn, or early in spring, sow the seed in a bed of light earth, and rake it in; and when the plants are come up three inches high, thin out a quantity, and plant them either in nursery-rows a foot distance, or at once where they are to remain.

By Roots.—The *Patientia* Dock, and variety, encrease by off-sets from the root, which being slipped in autumn, and the slips directly planted, they will readily grow.

And the *Rumex Lunaria*, or *Tree Sorrel*, is propagated easily by cuttings of the young shoots in spring and summer; if performed in spring, plant them in pots, and plunge them in a hot-bed, they will very soon emit roots; but in summer, they will succeed without aid of artificial heat, planted either in pots, or in a border of common earth, and occasionally shaded and watered, many of them will strike and be well rooted by autumn.

RUSCUS, Butchers Broom, and Alexandrian Laurel.

Consists of low shrubby, and under-shrubby ever-greens, for the shrubbery and greenhouse collection; rising some three or four feet high, others scarcely a foot; garnished with smallish, oblong, and lanceolate leaves,

some prickly, others smooth, from one to three inches long, and from half an inch to an inch broad, remaining all the year; and dioecious apetalous flowers, produced in most sorts, on the surface, and margin of the leaves, and in some at the ends of the branches.

Class and order, *Dioecia Syngenesia*.

Characters.] CALIX, Dioecious flowers, having spreading cups composed of six oval convex leaves.—COROLLA, no petals, but an oval erect nectarium, the size of the calix, open at the mouth.—STAMINA, no filaments, but three spreading antheræ, fitting on the nectarium, and join at the base.—PISTILLUM, an oblong-oval germen, hid within the nectarium, a cylindric style, crowned by an obtuse stigma, standing above the mouth of the nectarium.—PERICARPIUM, a round, or globular trilocular berry, having two round seeds.

This genus consists of five species, three or four of which are hardy for any open plantations; and the others tender, requiring shelter of a green-house in winter.

Hardy Kinds.

Under this head is comprised the common Butchers Broom—*Hypoglossum*, or Tongued Laurel—and Alexandrian Laurel; all of which are shrubby ever-greens of hardy growth.

**Ruscus Aculeatus*.

Prickly Ruscus, Common Butchers Broom, or Knee-Holly.] Hath a thick, fibrated, creeping, deeply-striking, white root; several erect, shrubby, tough, green stems, two or three feet high, closely garnished with small, oval, stiff, dark-green leaves, alternately, terminating in prickly points; and small, purplish flowers, situated on the upper surface of the leaves, succeeded in the female plants, by large red berries, ripening in winter.

This species grows abundantly in England, &c. in woods, and is introduced in many gardens, in wilderness, and shrubbery plantations for variety.

Great quantities of the young bushy plants of this species are brought to London in winter for sale; they being collected in the neighbouring woods, by the herb people, taking them up with a little ball of earth about the roots, wrapping the ball up with moss, and in that manner hawk them about the streets; and the citizens buy them to plant in pots of sand, to adorn rooms, where they will remain green a long time. It is also in much request among

among the butchers, for scrubbing brooms ; the branches being tied in bundles, forming a sort of broom, or besom ; and with which they scrub their chopping-blocks. Hence the name Butchers Broom.

²*Ruscus Hypophyllum.*

Hypophyllum, or Broad-leaved Italian Butchers Broom.] Hath thick, knotty, long-fibrated roots ; many ligneous, pliable, tough, green stems, two or three feet high ; oblong, oval, stiff, shining-green leaves, placed alternately, and bearing flowers on their under surface ; succeeded, in the female plants, by small red berries, ripening in winter.

³*Ruscus Hypoglossum.*

Hypoglossum, or Tongued Ruscus, commonly called Tongue upon Tongue Laurel.] Hath thick fibrey roots ; many ligneous, slender, pliable, green stems, ten or twelve inches high ; long spear-shaped leaves, each having a smaller leaf, like a tongue, issuing from its upper surface, and from the bottom of which are produced small yellowish flowers, succeeded by large red berries, ripening in winter.

It is a native of mountainous parts of Hungary and Italy.

⁴*Ruscus Racemosus.*

Racemose flowered Ruscus, or Alexandrian Bay, commonly called Alexandrian Laurel.] Hath thick, long, fibrey, whitish roots ; many shrubby, smooth, very pliable, shining-green stems, four or five feet high, producing branches alternate ways ; garnished with oblong-lanceolate, shining-green leaves ; and yellowish hermaphrodite flowers, terminating the branches in racemous clusters, succeeded by large red berries, ripening in winter.

This species having the name of Bay, and Laurel, and being of a fine pliant growth, is supposed to be the plant used by the ancients for composing wreaths to crown their victors, and eminent poets.

Variety.] With red-flowers.

The above four hardy species grow freely in any of the shrubby plantations ; and multiply exceedingly by off-set suckers from the bottom.

Tender Kind for the Green-house.

⁵*Ruscus Androgynus.*

Androgynous Canary Ruscus.] Rises with shrubby, pliant stems, five or six feet high, producing many side branches ; garnished with oblong, stiff leaves ; bearing small white flowers on their edges, succeeded by reddish berries.

All the above five species of *Ruscus* flower abundantly in June and July ; four of which producing their flowers wholly upon the leaves, exhibit a curious singularity ; and the *Ruscus Androgynus* in particular, which having its flowers closely set all along the edges of the leaves, effect a singular and beautiful appearance ; and the hardy sorts are often succeeded by ripe fruit in our gardens in winter.

All the hardy sorts are proper furniture for the verges of shrubberies, or any close plantations, as they thrive under the drip of trees, and will remain green the year round, and increase the variety of those compartments.

The tender sort requires shelter of a greenhouse in winter, so must be planted in pots and managed as other shrubby exotics of that department.

The propagation of all the sorts is very easy, as they increase very fast by the roots, which sending up numerous stalks or suckers, they may be taken up in autumn, winter, or spring, in open weather, and divided into many separate sets, each forming a proper plant ; though they need not be divided too small, unless where a great increase is required, planting the largest at once where they are to remain, and the smallest in nursery-rows, &c. each plant will soon encrease by off-sets, and assume a bushy growth.

They may also be raised from seeds, though not expeditiously, for the seed often remains in the ground till the second spring ; so that of the hardy sorts in any bed or border an inch deep ; and the tender kind in pots, and placed under shelter, in cold weather ; and when the plants are a year old, it is proper in March to prick them out, the hardy sorts in nursery-beds, for two or three years ; and the tender sort in pots.

RUTA, Rue.

It consists principally of under-shrubby plants for the kitchen-garden and pleasure-ground ; adorned with many-lobed leaves, and small tetrapetalous flowers, growing in bunches.

Class and order, *Decandria Monogynia.*

Characters.] *CALIX*, is short, five-parted, and permanent.—*COROLLA*, four-oval, spreading petals.—*STAMINA*, ten awl-shaped patent filaments, having short erect antheræ.—*PISTILLUM*, a gibbous, cross-furrowed germen, having ten punctures, an erect style, and simple stigma.—*PERICARPIUM*, a gibbous, five-lobed, quinquelocular, capsule, opening.

opening in five parts at top, having many reniforme, angular, rough seeds.

There are three species, one of which only a shrubby, perennial; is common to the English gardens, comprehending some varieties, valued chiefly as medical plants, and sometimes to diversify the shrubbery.

The species is,

RUTA Graveolens.

Graveolent Ruta, or common Garden Rue.]

Rises with a shrubby, very branchy stem, four or five feet high, forming a bushy head; closely garnished with decompound, many-lobed, strong-scented grey leaves; and the branches terminated by bunches of yellow flowers, having torn petals, and the lateral flowers quadrifid, succeeded by ripe seeds in autumn.

Varieties.] Common broad-leaved garden Rue—narrow-leaved Rue—broadest-leaved Aleppo Rue—narrow-leaved Aleppo Rue—variagated-leaved Rue.

They all flower in June, and ripen plenty of seed in autumn, particularly the common sorts.

All these varieties of this species are hardy enough to succeed in the open ground, tho' the two Aleppo Rues should have a sheltered situation, and dry soil; and it is adviseable to pot some of those two sorts to move, to shelter of a frame, or green house, in winter; the variagated kind should likewise have a dry, poor soil, otherwise is apt to become vigorous, and lose its variegations.

As to their uses in gardening: the common broad and narrow-leaved Rues, are esteemed principally as medicinal plants, and as such merit culture in every garden, allowing them generally a dry soil, and may be raised both by seed, and by slips or cuttings; and afterwards planted out either singly about the borders; or where large quantities are

wanted, in rows two feet asunder, and a foot and half in the lines; but about London, where great quantities are raised for market, they commonly plant them in four-feet wide beds, in rows a foot asunder; which, after having one or two years growth, and formed into little bushy plants, are taken up in spring and summer, with balls, and carried to the markets for sale; they likewise pot many of them, both of the plain-green and variegated kind, which are also ready sale in market, to place, to adorn court-yards, balconies, &c.—But all the varieties may also be employed in the shrubbery compartments, in a dry situation, where they will effect an agreeable diversity, both in foliage and flowers.

The propagation of all the varieties is by seed, and by slips and cuttings.

By Seed.—The common Rue in particular may be raised plentifully by seed in the open ground; sowed in March or April, on a bed of light earth, and rake it in; they will soon come up, which, when two or three inches high, should be planted out in nursery-rows, and watered till fresh rooted.

From the scattered or self-sowed seeds of the common Rue, many young plants often rise in autumn and spring.

By Slips or Cuttings.—This is the most expeditious method of propagation for all the sorts, for every slip or cutting of the branches will readily grow; and is the only method of propagation, by which we can continue the different varieties distinct; therefore in spring, any time in March or April, slip or cut off a quantity of the young shoots, six or eight inches long, and plant them in a shady border, in rows half a foot asunder, giving a good watering, and repeat it occasionally, they will soon emit roots below, and shoots at top, so as to form little bushy plants by autumn.

S.

S A C

SACCHARUM, Sugar-cane, or Sacchariferous Reed.

The plants of this genus are tall-growing tender perennials, of the arundinaceous tribe, natives of the Indies, and retained here in our stoves for variety; one of which is a most valuable plant, as from the juice of its stalks is prepared the various sorts of sugar; they rising with erect strong stems, eight or ten feet high, adorned with very long leaves, and terminated by large panicles, and spikes of numerous bivalvous flowers.

Class and order, *Triandria Digynia*.

Characters.] **CALIX**, none, but a woolly-down incloses each flower.—**COROLLA**, is bivalve; having too oblong-lanceolate, acuminate, concave valves.—**STAMINA**, three capillary filaments, as long as the valves, and oblongish antheræ.—**PISTILLUM**, a subulate germen, two cirrhone styles, and simple stigmas.—**PERICARPIUM**, none, one narrow sharp-pointed seed to each floret, invested by the valves.

The species are,

¹**SACCHARUM** *Officinarum*.

Common Sugar Cane.] Hath a long thick-jointed, fibrated, succulent root; sending up several upright, round, jointed stems, from six or eight to ten feet high, or more, abounding with a pithy saccharine juice; having at each joint large oblong leaves, three or four feet long, the base embracing the stalk a considerable way up; and the stalks terminated by very large panicles of numerous small flowers.

This species is the true Sacchariferous Cane, from which the sugary juice is expressed, which being boiled and refined, becomes that well known useful substance called Sugar.

²**SACCHARUM** *Spicata*.

Spiked Sugar Cane.] Hath a thick-jointed fibrated root; upright jointed stems, six or eight feet high; oblong, waved leaves, two or three feet long; and the stalks terminated by spikes of purplish flowers.

S A C

Both these species are perennial in root; the stalks rise several from each root; and in their growth resemble the *arundo*, or common reed of the marshes, but considerably larger, and instead of being hollow like those plants, are filled with a whitish pith, containing the sweet juice, or liquid, which renders these plants so very valuable; the stems are strong, but brittle, generally growing to perfection in, from six or eight to twelve or fourteen months, becoming of a pale-yellowish colour; producing at top numerous small flowers, collected into very large panicles, &c. sometimes two or three feet long, each flower having only two small valves for the corolla, and is wrapped up in long down; succeeded by oblong, narrow seeds included in the valves.

But it is the first sort, *Saccharum Officinarum*, that is cultivated for sugar, and for which purpose prodigious quantities are raised in the West-Indies, and other hot countries; being propagated by suckers and cuttings, planting them in fields, in rows four or five feet asunder, which soon shoot up into stalks, becoming fit to cut for use sometimes in six or eight months, being then taken to a mill and squeezed between iron-cased rollers, to express the juice, which is then properly boiled and refined to form it into a due consistence to become Sugar.

From the skimmings of the Sugar in the different boilings, and melasses, being the last drainings of the Sugar, mixing therewith a quantity of water, and the whole fermented, is extracted that spirituous liquor called rum, abounding with a salutiferous oiliness, whence proceeds the excellence of that spirit, compared with brandy.

In this country however, this valuable plant cannot be cultivated without the aid of a hot-house all the year; so that only a few are raised by way of curiosity, being planted in pots of rich earth, and placed in the stove.

Method of Propagation, &c.

Their propagation is effected abundantly by slips or suckers from the root, and by cuttings of the main stalks.

In this country however, they are more generally propagated by slips from the bottom, or any side-shoots arising from the stems near the root, having earth raised about the bottom part, will soon emit fibres, and be fit for separation; observing, these slips or off-sets may be taken off at any season, in which they appear fit for the purpose, being careful to detach them with some fibres to each, and plant them separately in pots of rich earth, and plunged in the bark-bed, watered, and occasionally shaded till they have got root; retaining them always in the bark-bed in the stove; and managed as other exotics of that repository.

But in the West-Indies, &c. these plants are most commonly propagated by cuttings of the tops of the old canes, or any part thereof, divided into lengths of from twelve to eighteen inches long, and placed horizontally in the ground three or four inches deep.

SALIX, Sallow, or Willow-tree.

The Sallow and Willow are principally of the tree kind of the deciduous tribe; valuable both as timber trees for various light uses, and for all sorts of basket-work, poles, &c. Some sorts also to diversify garden plantations, there being many species, growing from twenty to thirty or forty feet high, or more, garnished with oval, spear-shaped, and oblong leaves, in different trees, and dioecious apetalous flowers, disposed in amentums.

Class and order, *Dioecia Diandria*.

Characters.] **CALIX**, male and female flowers on separate plants, disposed in oblong, scaly, imbricated, katkins, or amentums, each scale containing one floret.—**COROLLA**, no petals, but cylindric nectarious glands in the centre.—**STAMINA**, in the males, generally two filaments, crowned with didymous quadrilocular antheræ.—**PISTILLUM**, in the females, an oval narrow germen, a scarcely distinguishable style, having two erect bifid stigmas.—**PERICARPIUM**, an oval-subulate, unilocular, bivalved capsule, having many small seeds crowned with down.

There are about thirty different species of this genus, mostly of the tree kind, of hardy growth, and some low under-shrubby, and herbaceous-like plants of no use; so that the tree kinds only merit consideration for gene-

ral culture, several of which grow to timber-trees; others are of great value to the basket-makers, being planted in marshy grounds, kept to low stools to produce a crop of shoots, or twigs to cut annually, for all kinds of wicker-work; and others being suffered to grow larger, to cut every three, or five, or six years for poles, useful for various purposes: and for garden culture, some particular sorts may be introduced thinly in large plantations for variety; and some sorts of the osier kinds should be planted in some moist place, to furnish twigs for tying various garden articles.

The principal tree kinds in England are, ¹**SALIX Caprea**.

Common Sallow Tree.] Grows to but a moderate height, having smooth, dark-green, brittle branches; oval, waved, rough leaves, indented at top, and woolly underneath.

Varieties.] Oblong, acute-pointed-leaved—silver-striped leaved.

It grows abundantly in this country, but more frequently in dry than moist situations; is of a brittle nature, so is unfit for the basket-makers; but will serve for poles, stakes, and to lop for fire-wood, and its timber is good for many purposes.

²**SALIX Alba**.

White, or Silver-leaved Willow.] Grows to a great height, and considerable bulk, having smooth, pale green shoots; long, spear-shaped, acuminate, sawed, silvery-white leaves, being downy on both sides, with glands below the serratures.

This is the common White Willow, which grows abundantly about towns and villages, and by the sides of rivers and brooks, &c.

³**SALIX Vitellina**.

Yellow, or Golden Willow.] Grows but to a moderate height, having yellow, very pliant, shoots; oval, acute, serrated, very smooth leaves, with the serratures cartilaginous, and with callous punctures on the foot-stalks.

⁴**SALIX Purpurea**.

Purple, or Red Willow.] Grows to a large height, having long, reddish, very pliable shoots, and long spear-shaped, serrated, smooth leaves, the lower ones being opposite.

⁵**SALIX Viminalis**.

Viminalous or Osier Willow.] Grows but a moderate height, having slender, rod-like branches, very long, pliant, greenish shoots; and very long, narrow, spear-shaped, acute, almost entire leaves, hoary, and silky underneath.

⁶**SALIX Amygdalina**.

Almond-leaved Willow.] Grows to a middling height, with long, flexible, light-green branches and shoots; spear-shaped, serrated, smooth, shining-green leaves, on short foot-stalks, having trapeza-shaped stipula.

⁷*SALIX Pentandria.*

Pentandrous, Broad-leaved, Sweet-scented Willow.] Grows to some considerable stature, having brownish-green branches; oblong, broad, serrated, smooth, sweet-scented leaves, shining above; and pentandrous flowers.

⁸*SALIX Triandria.*

Triandrous Willow.] Grows to a large stature, having numerous, erect, greyish-green branches, and pliant shoots; oblong, acute-pointed, serrated, smooth, shining-green leaves, eared at the base; and triandrous flowers.

⁹*SALIX Fragilis.*

Fragile or Crack Willow.] Rises to a middling stature, with brownish, very fragile, or brittle branches, long, oval-lanceolate, sawed, smooth leaves of a shining-green on both sides, having dentated-glandular foot-stalks.

This sort in particular being exceedingly fragile, so that it easily cracks and breaks, is unfit for culture in osier grounds.

¹⁰*SALIX Hastata.*

Hastated-leaved Willow.] Grows to a middling size, with long, green, pliable shoots; sub-oval, acute, serrated, smooth, close-fitting leaves, having heart-shaped stipula.

¹¹*SALIX Helix.*

Helix of Theophrastus, or Dwarf Yellow Willow.] Grows but to a very moderate stature, having a yellow, rough-barked trunk, with brownish branches; and narrow, lanceolate, serrated, smooth, blueish-green leaves, the upper ones obliquely opposite.

¹²*SALIX Babylonica.*

Babylonian pendulous Salix, commonly called Weeping Willow.] Grows to a largish size, having numerous, long, slender, pendulous branches, hanging down loosely all around in a curious manner, and long, narrow, spear-shaped, serrated, smooth leaves.

This curious Willow is a native of the East, and is retained in our hardy plantations for ornament, and exhibits a most agreeable variety; particularly when disposed singly by the verges of any piece of water, or in spacious openings of grass ground.

Other eminent Sorts distinguished by the following Names:—Sound-growing Norfolk Willow.—Upland red Willow.—Broad-leaved Flanders Willow—Swallow-

tail Willow—Dutch Osier—Wire Osier, &c. with some other varieties, particularly of the Osier kinds, found principally in the osier-grounds for the basket-makers, distinguished by different names, in different places.

The mode of flowering of all the sorts of Willows is, in amentums, or katkins from the sides of the branches, being male and female in different katkins on separate trees; ripening in March and April.

All the above species and varieties of *Salix* are of the tree kind, very hardy, and remarkably fast growers, and several of them attain a considerable stature, when permitted to run up to standards, which frequently grow forty or fifty feet high, in twenty or thirty years, having proportionably large trunks; though some sorts are apt to decay on the sides, when large, and others will remain sound to a considerable age and bulk: but all the sorts may be easily raised from cuttings, both as standards for timber; or kept down to dwarf stocks, for producing rods and twigs; or formed into pollards, or half-standards for loppings.

Most of the sorts grow naturally in England, &c. in great abundance, except the Triandrous and Hastated Willows, which grow chiefly in Switzerland; and the Weeping Willow is a native of the East; but are all hardy enough to grow any where.

They are mostly of the aquatic tribe, as being generally the most abundant, and of most prosperous growth in watery situations; they however will grow freely almost any where, in any common soil and exposure; but grow considerably the fastest and strongest in low moist land, particularly in marshy situations, by the verges of rivers, brooks, and other waters; likewise along the sides of watery ditches, &c. which places often lying waste, may be employed to good advantage, in plantations of willows, for different purposes.—Some for standards to grow to timber; some to form Osier beds, and kept down to stools, a foot high, to furnish an annual cutting of rods or twigs, for the basket-makers; which, being cut every year, pay well for the the ground and trouble. Other plantations to furnish poles, for cutting every three, four, five, or six years, for various uses: and some planted also for pollards, forming stems, eight or nine feet high; which, branching out numerously at top, furnish a lopping every four, five, or six years, both for poles, and for faggot-wood to burn. For all

of which purposes, they may be raised expeditiously by cuttings of all sorts, either of the young shoots, one or two feet long; or large truncheons or poles, of from three to eight or ten feet in length, planted particularly in moist places; for the cuttings of these trees are remarkably free of growth, so that sometimes, when used for common hedge-stakes, they strike root freely and grow up to large trees.

For ornamental purposes in gardening, may introduce any of the sorts in any hardy plantations for variety, as aforesaid; but more particularly the white Willow, yellow Willow, purple Willow, pentandrous sweet Willow, almond-leaved, and weeping Willow, being disposed thinly in large out-plantations, will effect an agreeable diversity: but the Babylonian, or weeping Willow, for its curious pendulous growth, demands culture in every garden; and which, for the general part, should be disposed singly or detached, both by the sides of water, and in spacious opens of grass ground; also near grottos, cascades, caves, ruins, &c. in all of which, it will effect a most agreeable variety, with its numerous, slender, pendulous branches, bending arch-ways all around, terminated by very numerous, long, slender, hanging shoots. Likewise plantations of all the sorts of Willow in assemblage with poplars, birch, and other aquatic trees, may be formed in any low watery situation, where other trees will not thrive, and they will exhibit an eligible diversity, as well as ornament the premises.

Likewise for garden-culture, should introduce some of the best Osier kinds, which are of great use for tying and binding particular articles; such as for tying the branches of espalier trees to the treillage; likewise in the nurseries for binding bundles of trees for sending to a distance; and in the market-gardens for binding their ware in bunches for market, such as celery, turneps, coleworts, leeks, horse-radish, &c. as practised by the London gardeners; also for tying up the leaves of early cabbages, &c. to facilitate their cabbaging and whitening in the heart: they are likewise useful for making and mending garden baskets occasionally: therefore it is proper, for all of those purposes, to plant a quantity of cuttings, of the best Osier kinds, in some moist situation, near water if possible, keeping them low, and they will furnish a crop of twigs annually; a quantity of which being

cut in winter, and tyed in bundles, may be preserved for use all the year, which, when become dry, they being thrown into water will supple them for use.

Method of Propagation and Culture.

All the sorts of Willows are propagated expeditiously by cuttings both of the young shoots of one or two years old, in lengths of half a yard or two feet long; and those of several years growth in truncheons or poles, of from three or four, to eight or ten feet long, according to the purposes for which they are designed, as mentioned below; all of which will most readily strike root, especially in low moist soils: and the season for planting them, is any time in open weather, from October until February: having generally a long iron-shod dibble, for planting the smaller cuttings, and an iron crow for making holes for the larger sets, or make holes with a spade for very large long cuttings; though some use no instrument in planting the smaller cuttings, but sharpen the ends of them, and thrust them into the ground, especially in soft land; but as this method is apt to force off the bark from the lower part of the cutting, it is therefore best to cut the bottom of each cutting even, and plant them with some instrument as above.

They are planted for different purposes; as for timber trees—to form osier grounds—to cut for poles—pollards for lopping, &c. So the cuttings must be prepared and planted according as directed below, under their respective heads.

For timber trees.—The timber of Willows is esteemed for several purposes, it being very white, of a fine grain, smooth, and takes a good polish, which renders it proper for many light articles: and, to raise them for timber, chuse the larger growing sorts, such as the white, yellow, and purple, or red willows, &c. taking cuttings of the strong young shoots, which may be planted at once where they are to remain, in any low marshy situation, where they will grow amazingly fast.

Having however prepared the ground, by proper digging, or plowing, as may be most convenient, and the situation admits; then provide a quantity of cuttings of strong young shoots, of one or two years growth, cut to half a yard, or two feet lengths, which plant in rows, only six feet asunder, and three or four distant in the rows, that they may draw each

each other up fast in growth, and allow for a gradual thinning, inserting each cutting two parts of three into the ground, by the method before observed; they will soon emit roots, and shoot strongly at top in spring and summer, observing to clear all away but one of the strongest leading shoots for a stem, which suffer to run up always at full length in its future growth; remarking, that in a few years, when the trees approach one another, they should be thinned, which thinnings will serve for poles for several uses, repeating the work of thinning in a few years more, according as the branches of the different trees interfere, leaving them at last about twelve or fifteen feet asunder, to attain full growth: thus they will draw each other up very expeditiously with straight handsome stems, forty or fifty feet high or more; and in twenty or thirty years, will be fit to fell for timber.

For Osier Grounds.—Osier grounds are plantations of osier Willows, in low stools for producing twigs annually for the basket makers, being formed in any low watery situation, planted with cuttings of the best osiers, and all the other most pliant sort of Willows, in rows two or three feet asunder, and always kept to low stools a foot high, in order to force out a more plentiful annual crop of twigs and rods, from three or four, to six or eight feet long, of a pliant tough nature, fit for working into all kinds of basket and wicker-work, which being cut annually in winter for sale, are worth from five or six, to eight or ten pounds an acre per annum: so that, osier plantations being thus formed in any low watery waste land, incapable of yielding other produce to perfection, will turn out to great advantage; and, if near any navigable river, for the convenience of water carriage, it will still be more advantageous: on which consideration, very large tracts of waste, boggy grounds and islands, along the river of Thames, is employed in osier grounds, for the London consumption.

Therefore, making choice of any convenient, low, moist situation, let it be digged or ploughed, for the reception of the osiers: then, in the proper season before-mentioned, gather a sufficient quantity of osier sets of different sorts, which must be cuttings of the one or two years old shoots, cut into two feet and half lengths; these being provided, then draw lines for planting them, two feet and half distance, inserting each cutting

about a foot and half into the ground, leaving the rest out to form the stool, and let them be two feet and half distance in each row: having thus formed the plantation, the cuttings will root firmly in the spring, and shoot at top tolerably strong in summer, each stool generally throwing out several shoots, of an erect growth; observing, during this first summer, to keep down all large weeds, that the stools may have full scope to produce the first shoots as strong as possible, which, by the end of autumn, will probably be advanced some considerable length; and if much wanted, may be cut in the following winter; though, for a full plantation, they should generally be suffered to continue their growth for two or three years, till the stools are firmly rooted and become strong; then cut down all the tops close to the head of the stools; they will serve for poles, &c. next year the stools will shoot out strong, a numerous crop of twigs and rods, fit for cutting for the basket-makers in winter following; and, the stools still remaining, furnish an annual crop, fit for cutting every winter, which should be cut always down to the head of the stool, as just above observed; sorting the twigs in sizes, tie them in bundles, and stack them up for use.

To cut for Poles.—Willow poles are useful for various husbandry purposes; such as for handles for implements, and for making hurdles, &c. and plantations of stools may be made in any waste, watery places, as before observed, to cut every three, or four, or five, or six years, according to the purposes for which they may be required.

For this purpose, procure a quantity of sets, of two year old shoots, in cuttings about two feet and half long; plant them in rows, a yard asunder, introducing each cutting two parts of three into the ground; they will all readily grow, and each send out several erect shoots, which, in three or four years, will become large poles fit to cut for use.

Or large cuttings or truncheons, three or four feet long, thrust down along the sides of rivers, brooks, ditches, &c. they will take root, and shoot out strongly at top for poles, as above.

To form pollard Standards.—Willow pollards are common almost every where, they being raised commonly from large sets or cuttings of poles, three yards long, or more, planted along the sides of rivulets or watery ditches, &c. and that being generally topped

or

or divested of the leading shoot, they do not run up with tall stems, but branch out all around, at seven or eight feet height, into many erect branches, which, in four, five, or six years, being lopped down to the head of the stem, serve for poles, for hurdles, &c. also for fuel, as before observed; and the pollards shooting out again, they in this manner furnish a lopping every fifth, sixth, or seventh year, and thereby prove very profitable for many purposes.

The sets or cuttings for raising these pollards, may be obtained in plenty from the loppings of any old pollard Willows, &c. chusing the large straight poles, cut into nine or ten feet lengths, which must be planted either with an iron crow, or some similar implement, driven into the ground, to make wide holes, two feet and half deep, for their reception; or, if the ground is impliant and stubborn, may dig holes with a spade that depth, planting one set in each hole, placing them two feet and half in the ground, leaving six or seven above for a stem: thus, these sets, though so large and long, if planted in moist places, will readily strike root, and shoot out at top the following spring and summer, into many erect branches, which, after four or five years growth, become fit to top for poles, &c. and the trees will thus continue to afford a lopping every fifth, sixth, or seventh year; or may grow larger, according to the purposes for which the loppings may be wanted.

To form Hedges. — Sometimes Willow hedges are raised in some outward place, along ditch sides, or elsewhere, when designed to form either a fence, blind, or shelter expeditiously; which is easily effected by cuttings, either of strong young shoots, cut into two or three feet lengths, and planted in a row half a foot asunder, and fifteen or eighteen inches deep; or with larger truncheons of several years growth, cut into sets, two, three, four, or five feet long or more; and in either case, that when the sets have made the first years shoot, the shoots may be plashed together in winter, both to stiffen the hedge and give it a thicker form: afterwards it may be kept regular by clipping it annually, or may be suffered to take its own natural growth, as occasion shall require.

Observe however, that to form a Willow hedge, as soon as possible, you may use large straight sets, of five or six feet long, and plant

them chequer-ways, placing each set half a yard or two feet in the ground, leaving three or four feet above; which, being arranged cross one another in the above mentioned chequer manner, and ranged all an equal height, they will at once form a good firm fence, immediately fencible against cattle.

Or, where a speedy fence is wanted, by way of blind or shelter, may procure a quantity of loppings, five, six, or seven feet long, well furnished with branches to the bottom, which plant in a deepish trench, pretty close together, they will grow and form a sort of fence directly.

To furnish Twigs for Garden Use — Osier twigs being useful in many gardens for various tyings, as we before observed, it is eligible to cultivate a few of the best osiers in most gardens, to furnish a supply for the different purposes; chusing some moist situation, or near any watery ditch, or other water in any bye place, or where most convenient: and, having procured a quantity of the most pliant kind of Osier sets, cuttings of young shoots, half a yard or two feet long, which plant in the place allotted in rows, planting or thrusting them two parts of three into the ground; they will grow freely, and furnish plenty of twigs every year, managing them as observed for those of the *Osier Ground*.

As to the culture of all the above different plantations of Willows, they require but little; which is principally the keeping down large weeds the first and second year after planting, which is more particularly requisite in the plantations of young low cuttings, till they are a little advanced in growth.

For Nursery Collections. — Collections of the different sorts of Willows, should also be kept in all nursery grounds, both public nurseries for sale, and in private nurseries, to supply plantations occasionally, raising them generally from young cuttings, of a year or two old, in half yard or two feet lengths, and planted in rows, two or three feet asunder, to grow till wanted.

SALLAD HERBS.

Various sorts of esculent herbs of different genera, are used for sallading, which by different sowings, plantings, &c. are obtained at all times of the year; but the most generally esteemed sorts, may be comprised under the following three heads. — *Principal Sallad Herbs.* — *Small Sallad Herbs.* — *Occasional Sallad Herbs.*

Principal

Principal Sallad Herbs.—These consist chiefly of three sorts, viz. lettuce, all the varieties—endive, all the different sorts—and celery, all the varieties—which three principal sorts are all raised from seed, by different sowings and transplantings; and are in best perfection for use when arrived to full growth: either of which may be eaten as a Sallad alone, or all of these sorts mixed together, or any, or all of them mixed with a proper quantity of small fallading, or other Sallad Herbs occasionally: but with small fallading in particular is very eligible in winter and spring; as the small fallading, being of a warm nature, renders the Sallad more grateful and wholesome. Lettuce is generally esteemed as the most material Sallad Herb, for general use, at most times of the year, but particularly in summer, when full grown and firmly cabbaged; but by several sowings and transplantations at different times, from January and February, until September or October, in different situations, according to the season, the plants may be obtained in tolerable plenty almost the year round, but always more finely cabbaged in summer than in winter. And as to the endive and celery, they are excellent for autumn and winter Sallads, they being in full perfection in September, October, and November, when they will be full grown and finely blanched, and they often continue in tolerable perfection all winter and spring.—But for other particulars, together with the method of culture of these three principal Sallad Herbs. See their respective genera, *LACTUCA*, *CICHORIUM*, and *APIUM*.

Small Sallad Herbs.—The principal sorts, denominated Small Sallad Herbs, are cresses, mustard, radish, rape, and turnip, also lap-cabbage-lettuce: all of which herbs, considered as small fallading, are always in perfection as such when quite young, or only a few days old, whilst in the seed leaf, cutting them up, shank and top together, close to the ground, as when they are thus quite young they eat exceeding tender, with an agreeably warm relish, for they being mostly of so warm a nature, that if suffered to grow old for fallading, they would eat very hot and disagreeably strong-tasted, but being used when quite young, as above, whilst they remain of a palatably warm relish, they are highly proper to mix in all winter and spring Sallads in particular; though many people are fond of them at most times of the year; and many often use them alone, particularly in winter

and spring; they, however, are preferable when mixed with lettuce and the other large fallading.

All these Small Sallad Herbs are raised from seed, which, for the purpose of fallading are sowed at all times of the year, when they are required, in the open ground in the spring and summer, and in winter under frames and glasses, and occasionally in hot-beds; and where a constant supply is wanted, a repetition of sowings is requisite every week, ten days, or a fortnight, being sowed generally in shallow flat drills, very thick, and only just covered with earth. But for the particular culture of these herbs for fallading, see the article *SMALL Sallad Herbs*.

Occasional Sallad Herbs.—This head comprehends several other excellent Sallad Herbs; but not being in such general estimation as the former sorts, are only used occasionally, viz. Corn Sallad or lamb's lettuce—purslane—spear-mint—water-cress—borrage and borrage-flowers—nasturtium-flowers—chervil—burnet; and sometimes red-cabbage—radishes—red beet-root—fennel or Azorian fennel—horse-radish—young onions, &c. each of which requiring a particular culture, we refer to their respective genera, where their uses as Sallad Herbs, &c. and mode of propagation, &c. is fully exhibited.

SALSOLA, Glass-wort, and Stone-crop-tree.

This genus is composed of herbaceous annuals and perennials of but little merit as garden plants, and one shrubby ever-green, proper for the shrubbery.

Class and order, *Pentandria Digynia*.

Character.] *CALIX*, five oval permanent leaves.—*COROLLA*, no petals.—*STAMINA*, five very short filaments inserted into the divisions of the calix.—*PISTILLUM*, a round germen, a double, or a tripartite style, and recurved stigmas.—*PERICARPIUM*, an oval unilocular capsule lodged in the calix, having one large seed.

There are many herbaceous species, and some of shrubby growth; one of the latter being the only sort generally cultivated in the English gardens, viz.

SALSOLA fruticosa.

Shrubby Glass-wort, commonly called Stone-crop tree.] Rises with a shrubby erect stem, branching numerous and erectly, four or five feet high, closely garnished with very small obtuse fleshy leaves, like the common Stone-crop on the walls.

This

This species was formerly retained in the genus *Chenopodium*, but is lately made a species of *Salsola*.

It inhabits the sea-shores in England, France, and Spain, &c. but is retained in many curious gardens, in the ever-green collection, to adorn the shrubbery compartments, allowing it generally a sheltered situation.

The propagation of this ever-green, is by suckers, layers, and cuttings; many stems generally rising from the root, which may be divided in autumn or winter, into so many separate plants; and layers or cuttings of the young branches in autumn or spring will be well rooted by autumn following.

SALVIA, Sage, Clary, &c.

It comprehends under-shrubby, herbaceous, and shrubby plants, both for the kitchen garden, pleasure ground, and green-house, garnished mostly with spear-shaped, oval, and oblong leaves, and small, monopetalous, ringent flowers, generally terminating the branches in spikes.

Class and order, *Diandria Monogynia*.

Characters.] CALIX, is monophyllous, wide at the mouth and bilabiated—COROLLA, is monopetalous, tubulous below and ringent above, having the upper lip concave and indented, and the under one broad and trifid.—STAMINA, two short filaments, split into two parts, one of which supports the antheræ—PISTILLUM, a quadrifid germen, a long slender style, and bifid stigma.—PERICARPIUM, none; four roundish seeds lodged in the calix.

To this genus *Salvia*, is now joined *Sclarea*, or common Garden Clary, and *Horminum*, or Wild Clary, &c. amounting in the whole to above thirty species, though not half so many that merit culture, as garden plants, consisting of hardy under-shrubby, and herbaceous perennials for the open ground, and shrubby ever-greens for the green-house.

Hardy under-shrubby kinds.

Under this head is comprehended, the common Sage of the kitchen garden, having many varieties; all under-shrubby perennials, exotics from the southern parts of Europe, but are all hardy enough to succeed here in the open air, the year round.

¹SALVIA *Officinalis*.

Common officinal Sage.] Rises with short, under-shrubby, hairy stems, branching numerously from the bottom, two feet high, or more, forming a very bushy head; spear-

shaped-oval, entire, slightly crenated, rough leaves, and the branches terminated by spikes of blueish flowers, having acute cups.

Varieties.] Common broad-leaved green Sage.—Common culinary red Sage, being of a black-red colour.—Broad-leaved, hoary, balsamic Sage, having generally the broadest leaves of all the sorts, standing on long footstalks.—Wormwood Sage.—Narrow-leaved hoary Sage, commonly called Sage of Virtue, having the base of the leaves sometimes auriculated or indented in form of ears, and sometimes not eared.—Lavender leaved Sage.—Variegated green Sage.—Variegated red Sage.

They all flower in June and July, and are sometimes succeeded by ripe seed in autumn.

This species and varieties are all very hardy plants, perennial in root, stem, and branches, and retain their leaves the year round. They are plants of sovereign virtue, as the name imports, and the leaves are the only useful part, being proper for various culinary purposes, and for medical uses; are also often used in the manner of tea, by way of medicine, and eaten with bread and butter, and used for making sage-cheese, &c. these plants therefore, demand culture in every family-garden; and any, or all the sorts may be cultivated for use, they possessing nearly all the same quality; but the red Sage is the most commonly cultivated for general kitchen purposes; and the broad-leaved hoary Sage, and the Sage of Virtue, is often preferred for tea and other medical uses, though it is probable any of the sorts may be equally eligible, as being all varieties of one species.

Hardy herbaceous kinds.

There are many herbaceous species of *Salvia*, some of which formerly composed different genera, such as *Sclarea*, or Garden Clary, and *Horminum*, or Wild Clary, &c. are mostly of foreign growth, but grow freely in our gardens, in the open ground; though they possess no great merit, except one for culinary and medical use; and the others principally as plants of variety, and consist of biennials, perennials, and annuals, garnished mostly with broad rough leaves.

The most noted species are,

²SALVIA *Sclarea*. (*Biennial*.)

Sclarea or common Garden Clary.] Hath a fibrated biennial root, crowned with broad, oblong, heart-formed, serrated, rough, hairy leaves;

leaves; upright, thick stems, two feet high, branching oppositely, having all the branches terminated by large loose spikes of pale blue flowers, attended by concave acuminate bractea, longer than the corolla and calix.

Varieties.] Broad-leaved—Long-leaved—Most wrinkled-leaved.

This species and varieties, are biennials, have all large, thick, woolly leaves, that impart a strong odour, and are the useful part of the plants, which are cultivated in kitchen-gardens, for culinary uses; being raised from seed annually, and planted out a foot and half asunder, where they spread out into large leaves for use, till next summer; when they shoot up into stalk for flower and seed; then totally perish.

³*SALVIA, Verbenaca.* (Perennial.)

Verbenaceous common Wild Clary, or Oculus Christi.] Hath a fibrated perennial root, oblong, sinuated, ferrated, wrinkled leaves; and declinated stems, a foot long, terminated by whorled spikes of small blue flowers, having the corolla narrower than the calix.

It grows wild in England, &c. its virtues are supposed nearly the same as the garden-clary; and the seed being of a viscous nature, is sometimes used for clearing the eye from any moat that happens to fall into it, putting one of the seeds into one corner, and moving it about, the dust sticking thereto, removes it out of the eye.

⁴*SALVIA Indica.* (Perennial.)

Indian Clary with a variegated Flower.] Hath a fibrated perennial root, upright four-cornered stems, three or four feet high, heart-shaped, acutely crenated leaves, the upper ones sessile, and half the upper part of the stalks adorned with blue variegated flowers, in remote whorls.

⁵*SALVIA Glutinosa.* (Perennial.)

Glutinous yellow Clary.] Hath a strong, fibrated, perennial root; heart-shaped, saggitated, acutely ferrated, glutinous leaves, upright four-cornered, glutinous stems, three or four feet high, terminated by spikes of yellow flowers, in close whorls.

⁶*SCLAREA Horminum.* (Annual.)

Horminum, or purple-topped annual Clary.] Rises with upright stalks, a foot and half high, obtuse crenated leaves, and the stalks terminated by whorled spikes of small purplish flowers, with coloured bracteal leaves at top.

Varieties.] With purple tops—with red tops.

All these herbaceous species flower mostly in June, and the seeds ripen in autumn.

They are all hardy enough to grow in any common soil, the first of which being for the kitchen-garden, and the others to encrease the variety of the herbaceous collection.

Tender shrubby kinds for the Green-house.

Consists of four or five shrubby ever-green plants of the Sage kinds, natives of different warm countries, and retained here in our green-house collections for variety.

⁷*SALVIA Mexicana.*

Shrubby Mexican Sage.] Rises with a shrubby branchy stem, eight or ten feet high; having four-cornered, purplish branches; oval leaves, pointed at both ends, and ferrated; and close spikes of blue flowers at the ends of the branches.

⁸*SALVIA Africana.*

Shrubby African Sage.] Rises with a shrubby branching stem, four or five feet high; roundish ferrated grey leaves, truncated and indented at the base; and whorled spikes of blue flowers towards the ends of the branches.

⁹*SALVIA Aurea.*

Golden African Sage.] Rises with a shrubby branching stem, six or seven feet high; roundish entire leaves, truncated and indented at the base; and short spikes of golden coloured flowers at the ends of the branches.

¹⁰*SALVIA Pomifera.*

Pomiferous or Apple-bearing Sage of Crete.] Rises with a shrubby branchy stem, four or five feet high, spear-shaped, oval, entire, slightly crenated, hoary leaves, and spikes of blue flowers, having obtuse cups.

The branches of this sort have sometimes glandular protuberances as big as apples; hence the name Pomiferous Sage.

¹¹*SALVIA Canariensis.*

Canary Sage.] Rises with a shrubby branching downy stem, garnished with hastated-triangular, obtuse, crenated leaves; and whorled spikes of blue flowers at the ends of the branches.

All the above species of *Salvia*, both hardy and tender kinds, are principally of the verticillate tribe, or such as produce their flowers in a verticillus, or whorls round the stalks, some having the whorls standing almost close, others placed remote (see *VERTICILLATUS* and *VERTICILLUS*); and the flowers are universally monopetalous and ringent,

gent, and generally small, but numerous in each spike. See the *Characters*, &c.

All the under-shrubby and shrubby kinds, both hardy and tender sorts, are durable in root, stem, and branches, and remain in leaf the year round.

But the herbaceous kinds are furnished with stems only in summer.

The *Salvia Officinalis*, or common Sage and varieties, considered as culinary and medical plants, merit culture in every kitchen-garden, allowing them a moderately dry soil, and sunny situation, to enable them to stand the winter more effectually; for if planted in moist or shady places, they are liable to suffer by severe frosts: they are easily raised from slips, as hereafter directed, and afterwards planted in rows a foot and half asunder; in which they will grow large bushy plants, and remain several years, furnishing leaves plentifully the year round; which are proper for use, both fresh gathered from the plants, and when dried; though for culinary purposes, they are best when fresh gathered, taking the young side-shoots or tops, slipping or cutting them off: and towards the latter end of summer, about July or August, gather a quantity to dry for tea: being careful in all the gatherings not to stump them too close, particularly in autumn and winter.

But the varieties of the common Sage, may also be employed to diversify the fronts of small shrubby clumps, &c. particularly the variegated kinds.

As to the merit of the herbaceous kinds, the *Garden Clary* being a culinary and medical herb, must be stationed in the kitchen-garden; and all the others, being considered principally as plants of variety, as aforesaid, may be employed to diversify any of the compartments of the pleasure ground; all of which herbaceous kinds are easily raised from seed; and the seedlings, when two or three inches high, should be planted out. See their *Propagation*, &c.

And as to the tender shrubby kinds, they requiring shelter from frost, must be kept always in pots, in order for moving to a greenhouse in winter; and as being elegant evergreens, they will effect an agreeable variety among the exotics of that conservatory.

Propagation and general Culture of the common Sage kinds.

The propagation of all the varieties of common Sage, is effected plentifully by slips or cuttings of the young shoots from the sides

of branches; and may also be raised from seed.

By slips or cuttings.—The slips both of the former and same years growth, planted in April or May, will readily grow. Slips of the former years shoot may be obtained plentifully any time in spring, but should not be planted earlier than April; which however, if planted any time in April, or early in May, they will root freely, and form good plants against winter: but young slips, shoots of the year, are rarely fit for slipping before the middle of May, or beginning of June: these however most readily strike root in a short time, and assume a free growth: in either case, taking opportunity of moist weather, and having recourse to some good bushy plants; slip off a quantity of the most robust side-shoots, about five, six, or seven inches long; trim off all the lower leaves, then in some shady border proceed to plant them with a dibble in rows, half a foot asunder, planting them down almost to their tops; giving water directly, to settle the earth close, as well as to promote an early emission of fibres, repeating the waterings occasionally in dry weather; and the slips will soon emit fibres, and shoot freely at top: observing, if they should spindle up with slender shoots, or run up to flower, it is proper to top them, in order to force out laterals, to assume a bushy growth: thus they will form tolerable bushy plants by August or September; when, or in spring following, they may be removed, with balls of earth about their roots, and planted where they are finally to remain, either in four feet beds, or in continued rows, a foot and half asunder, if designed as a close plantation for use: and those designed for the pleasure ground should be disposed accordingly.

Sometimes Sage, as before observed, having grown into large bushy plants, with numerous branches rising near the ground, which touching the earth, have formed plenty of fibres at bottom; and that being slipped off separately with the fibres thereto, each immediately commences a proper rooted plant; they may either be slipped off as the plants stand in the ground, or the bunches of plants may be taken up and divided into as many separate slips as are furnished with roots: and as they thus directly form rooted plants, they may be planted at once where they are to remain.

However, those raised from young slips, generally form the strongest bushy plants in the end.

By

By Seed.—The raising these plants from seed, is hardly worth practising, since they may be propagated so easily by slips or cuttings. However, the season for sowing the seed, is any time in April, in a bed of light rich earth; sow it evenly, and rake it in; the plants will soon come up: and when about two or three inches high, prick out the strongest in nursery-rows, half a foot asunder, to gain strength till September or spring following; then transplant with balls, where they are always to stand.

As to the culture of this species of Sage and varieties, all that is required is, the keeping them clean from weeds in summer, cutting down the decayed flower-stalks in autumn, and slightly digging between the rows in winter; and, if the ground should be impoverished, add a portion of rotten dung occasionally in autumn, and dig it in.

Propagation, &c. of the herbaceous kinds.

All the herbaceous kinds of *Salvia* are easily raised from seed: sowed in spring in the open ground; and the perennial sorts also, by parting the roots.

By Seed.—The Garden Clary, being a biennial, must be raised every year from seed. Sow it in March, in any bed or border of common earth, and rake it in; and when the plants have got leaves two or three inches long, plant them out in showery weather, in rows eighteen inches distance, and the same distance in the rows; they will soon get root, and grow large, and furnish large leaves, fit for use in autumn, winter, and the following spring.

The perennial sorts are also raised from seed, sowed in a bed of light earth in March, and raked in, and the seedlings planted out in summer, in nursery-rows till autumn, then transplanted into the borders, &c.

And the annual sorts may be sowed in spring, about the borders, in patches to remain.

By Parting the Roots.—The perennial kinds only can be increased by this method, which may be performed in autumn, or early in the spring.

Propagation, &c. of the tender shrubby kinds.

All the five tender shrubby kinds for the green-house, are easily propagated by cuttings of the young shoots in spring and summer. If in spring, a quantity of cuttings planted

in pots, and plunged in a hot-bed, will very soon emit roots at bottom, and shoots at top, when they should be gradually hardened to the full air. But cuttings planted in summer, will often strike without the aid of a hot-bed, planted either in pots, or in a bed of natural earth, under frames and lights, or covered close with hand-glasses, shaded from the mid-day sun, and occasionally watered.

The plants must afterwards be potted off separately, and managed as other shrubby exotics of the green-house. See GREEN-HOUSE PLANTS.

SAMBUCUS, Elder-tree.

This genus consists of hardy deciduous trees and shrubs, and herbaceous perennials, proper for some useful purposes in gardening and for diversifying hardy plantations; also for domestic and medical uses in their leaves, flowers, and fruit; are all garnished with large winged leaves and numerous small rotaceous flowers, mostly in cymose umbels towards the ends of the branches, succeeded by large bunches of black and other coloured berries in autumn.

Class and order, *Pentrandria Trigynia*.

Characters.] CALIX, is small, monophyllous, five parted, and permanent.—COROLLA, is monopetalous, rotated, and concave, and cut into five obtuse reflexed segments.—STAMINA, five awl-shaped filaments, having roundish antheræ.—PISTILLUM, an oval germen under the corolla; no stile, but instead thereof, a swelling glandule and three obtuse stigmas—PERICARPIUM, a roundish unilocular berry including three angular seeds.

There are only four species in this genus, three of which are of the tree and shrub kind, and one is an herbaceous perennial: two of them are common in England, &c. namely, the Common Black Elder-tree, and the Herbaceous Dwarf Elder; the other two are foreigners, one being from the south of Europe, and the other of America; but are all hardy enough to grow here in any situation.

Tree and shrub kinds.

¹**SAMBUCUS Nigra.**

Common Black Elder-tree.] Rises with a tree-stem, branching numerously into a large spreading head, twenty or thirty feet high; pinnated leaves, of two or three pair of oval lobes and an odd one; and large, cymose, five-parted umbels of white flowers towards the ends of the branches, succeeded by large bunches

bunches of black, and other different coloured berries, in the varieties.

Varieties.] Common Black-berried Elder-tree.—White-berried Elder.—Green-berried Elder.—Lacinated or Parsley-leaved Elder, having the folioles much lacinated, so as to resemble parsley-leaves. — Gold-striped-leaved Elder.—Silver-striped Elder.—Silver-dusted Elder.

All these being varieties of *Sambucus Nigra*, have, for the general part, five or seven-lobed leaves; are of a tree-like growth, and quinquepartite umbels of flowers and fruit; the common Black-berried Elder, however, is the most generally known variety, and the most commonly cultivated; sometimes as standards among forest trees, but more frequently in forming outward hedges expeditiously, as being a very fast grower; likewise often in detached standards for the sake of their berries for making of Elder-wine; and all the varieties may also be employed for diversifying plantations: all the varieties make very strong shoots, full of a white pithy substance, but becomes woody as they advance in age, and the old wood becomes solid and very hard, fit for many purposes: all of which varieties will grow in any situation, and may be raised very expeditiously by cuttings of the year-old shoots. See the *Propagation*.

The bark, buds, leaves, and flowers are used in medicine, being sovereign in many disorders.

And the ripe berries make an excellent cordial wine.

²*SAMBUCUS Racemosa.*

Racemose Red-berried Elder.] Rises with a tree-like stem, branching ten or twelve feet high, having reddish-brown branches and buds; pinnated leaves of six or seven oval deeply-sawed lobes, and compound, oval, racemous clusters of whitish-green flowers, succeeded by oval clusters of red berries.

This is a resident of the mountainous parts of the south of Europe, and is retained in our gardens as a flowering shrub, having a peculiar singularity in its oval-clustered flowers and berries.

³*SAMBUCUS Canadensis.*

Canada Shrubby Elder.] Rises with a shrubby stem, branching eight or ten feet high, having reddish shoots; somewhat bipinnated leaves, often ternate below, the others composed of five, seven, or nine oval lobes; and towards the ends of the

branches, cymose, quinquepartite umbels of flowers, succeeded by blackish red berries.

Herbaceous kind.

⁴*SAMBUCUS Ebulus.*

Ebulus, or Herbaceous Elder; commonly called Dwarf Elder.] Hath a thick, creeping, tough, perennial root, spreading widely around; herbaceous, strong, pithy, green stems three or four feet high; large pinnated leaves, of from three or four to six or seven pair of long, acute-pointed, indented lobes, with leafy stipula, and large, cymose, three-parted umbels of white flowers, succeeded by black berries in autumn.

This is a perennial, and grows wild in England in hedges, banks, and fields, but is admitted in some gardens for variety and medical uses.

Variety.] Lacinated-leaved, having the folioles beautifully jagged into segments.

All the sorts of Elder are of the deciduous tribe, very hardy, and grow freely anywhere; are generally free shooters, but particularly the *Common Elder* and varieties, which make remarkably strong, jointed shoots, of several feet length, in one season; and they flower mostly in summer, except the *Racemose Elder*, which generally begins flowering in April; their modes of flowering being in cymose umbels, and racemose clusters, as in their respective descriptions; rising generally towards the termination of the preceding year's shoot, each bunch consisting of numerous small, wheel-shaped, concave, semi-quinquefid flowers; and the bunches being large, spreading, and very abundant, are exceedingly conspicuous; but they emit a most disagreeable odour; are succeeded in most of the sorts, by large bunches of ripe berries in autumn, which, although very unpalatable to eat, are in high estimation for making that well known cordial liquor called Elder wine, particularly the common Black-berried Elder.

The merit of Elders in gardening may be both for use and ornament, especially in large grounds.

With respect to the tree and shrub kinds, the Common Elder may be introduced occasionally in forest-tree plantations, and as detached standards, in any bye-place, for the sake of their berries, as before hinted; and all the sorts may be employed to diversify large ornamental plantations, disposed, however,

ever, but thinly, particularly the Common Elders, as their flowers send forth a strong disagreeable scent, so should be but sparingly introduced near much frequented places; however, the different varieties thereof may be dispersed in out-plantations so as to effect an agreeable diversity; but as to the *Sambucus Racemosa* and Canada Elder, they may be disposed in any of the shrubbery compartments, more particularly the former, which will exhibit a conspicuous singularity in its mode of flowering and fruiting.

And the Common Elder, being a very fast grower, is often employed in forming outward hedges along ditch-sides, or the sides or tops of banks, where it is necessary to form a hedge-fence as cheap and expeditiously as possible, which may be raised from cuttings of the strong shoots of from one or two to five or six feet long, planted at once where the hedge is intended, a foot distance in the row, and from one to two feet deep in proportion to their length; but the short and middling cuttings generally form the closest hedge from the bottom: though long cuttings are sometimes used in order to form an immediate fence, which being arranged chequer-ways will render the fence stronger, and more immediately fencible against cattle. The hedges, raised by either method, if designed merely as a fence, should be trained only to a moderate height, and kept close and regular by an annual clipping: but some suffer these Elder hedges to grow up high without any trimming, especially at top, permitting them to branch out on each side upward, in order to produce large crops of berries, either for private use or for sale.

As to the *Ebulus*, or Dwarf Elder, it is sometimes admitted in gardens, by way of variety, in the herbaceous collection, and for medical use; observing, as this perennial multiplies exceedingly by its creeping root, it must be occasionally trimmed at bottom to confine it within moderate limits.

Method of Propagation, &c.

All the tree and shrub Elders are propagated very expeditiously by cuttings of the young yearling shoots, and may also be easily raised from seed.

By Cuttings.—Cuttings of Elder shoots, in lengths of from one or two to five or six feet, very readily grow, and autumn, or any time in open weather, from October till spring, is the proper season for planting

them; choosing cuttings of the last year's shoots, not those that are green and succulent, but such as are become a little woody; observing, that if they are designed for nursery-rows, to train occasionally for different purposes, cut them into short lengths of about three joints, planting them in rows two feet asunder, each cutting two parts of three in the ground: they will readily emit roots in the spring, and shoot strongly at top in summer, training them for the purposes wanted, some to run up with a single stem for standards, others to form bushy shrub-like plants, &c. and in a year or two they may be transplanted finally, if required.

Or if intended to form an Elder-hedge, cuttings of the Common Elder, of the above length, may be planted at once, where the hedge is intended, either in a single or double row, about a foot asunder.

But in some particular cases, large cuttings of from a yard to five or six feet long, or more, particularly of the Common Elder, may be planted in any moist situation, or along ditch-sides, either to form spreading standards, as soon as possible, for producing plenty of berries, or to form a growing hedge immediately fencible, as it were; in either case, planting the cuttings of this length half a yard or two feet deep, and ten or fifteen feet asunder, for the standards, and one foot apart for the hedge, arranged either slanting or chequer-ways, as before observed.

The planting of all these cuttings may be performed either with a long iron-shod dibble, or with an iron crow, or large stake driven into the ground to make holes for the long sets: or, sometimes, in moist, soft, deep soils, the ends of the cuttings being sharpened, they may be thrust into the ground a proper depth, especially the moderate-sized cuttings.

By Seed.—This mode of propagating Elders is not generally practised, they being much more expeditiously raised from cuttings as above; however, they may also be easily raised in abundance from the seed or berries, sowed in autumn, in beds of common earth, half an inch deep, and managed as other nursery seedling trees.

The scattered or self-sowed seeds of these trees, falling any where accidentally, either on the ground, in the crevices of old walls, or hollow trees, grow without care or trouble, and produce young plants.

The

The fourth sort, *Sambucus Ebulus*, is propagated very plenteously by parting the roots in autumn.

SAND, See COMPOSTS, EARTH, LOAM, &c.

SANGUINARIA, Puccoon.

It consists of one low, herbaceous, flowering perennial for the flower borders, rising with a low stalk, crowned with octa-petalous flowers.

Class and order, *Polyandria Monogynia*.

Characters.] CALIX, two oval concave leaves that fall away.—COROLLA, eight oblong, obtuse, spreading petals.—STAMINA, many short filaments, having single antheræ.—PISTILLUM, an oblong compressed germen, no style, but a thick, two-furrowed, permanent stigma.—PERICARPIUM, an oblong-bellied bivalvular capsule, having many roundish acute seeds.

There is but one species, *viz.*

SANGUINARIA *Canadensis*.

Canada Sanguinaria, or Puccoon.] Hath a tuberous fibrated root, crowned with large, roundish, indented leaves, and low, slender, leafless stalks, terminated each with one large, octa-petalous, pure-white flower.

Varieties.] Single-flowered,—Semi-double-flowered,—Full-double-flowered.

They are all perennial in root, but annual in stalk and leaves; the stalks rising in the spring, and flower in April, very ornamentally.

All the varieties are hardy, and proper to intermix with other low spring flowers in the fronts of the borders and other compartments; should be planted in autumn, when the stalks and leaves are decayed, any time from August till October, planting them about a foot, or fifteen or eighteen inches from the edge of the border, and about two or three inches deep, and they will all flower in spring following.

They are all easily propagated by parting the roots in autumn, when the leaves and stalks decay.

SANTOLINA, Lavender Cotton.

This genus furnishes low, under shrubby ever-greens, and herbaceous perennials, for ornamenting the pleasure-ground and for medical use, garnished with very small hoary leaves, simple and pinnated, in different species, and compound rayless flowers terminating the branches.

Class and order. *Syngenesia Polygamia Superflua*.

Characters.] CALIX, a hemispherical,

imbricated, general cup.—COROLLA, a compound uniform flower, consisting of numerous hermaphrodite funnel-shaped florets.—STAMINA, five fine hair-like filaments, and cylindric tubulous antheræ.—PISTILLUM, an oblong tetragonous germen, filiforme style, and two oblong, depressed, truncated stigmas.—PERICARPIUM none; each floret is succeeded by one four-cornered seed, resting on the common receptacle.

There are four species; two of them are shrubby and two are herbaceous; all, originally, exotics from the south of Europe, but hardy enough to prosper here, in the open ground, all the year.

Shrubby kinds.

Consists of two low, shrubby, bushy perennials, comprising some varieties, all durable in root, stem, and branches, and retain their leaves the year round, mostly assuming a hoary-whitish appearance.

¹SANTOLINA *Chamæ Cyparissus*.

Chamæ Cyparissus, Dwarf Cypress, or Common Lavender Cotton.] Rises with a low shrubby stem, very branchy and bushy, two or three feet high, very closely garnished with small taper, quadrifariouly-indented hoary leaves; and the branches terminated by long peduncles, each supporting one compound yellow flower.

²SANTOLINA *Rosemarinisolia*.

Rosemary-leaved Lavender Cotton.] Rises with a shrubby stem, branching numerously from one or two feet to a yard high, in different varieties, closely garnished with small linear hoary leaves, with tuberculated margins, and the branches terminated by long pedunculi, each sustaining one compound pale-yellow flower.

Varieties of this.] Greater Rosemary-leaved Lavender Cotton, growing about a yard high—Minor Rosemary-leaved Lavender Cotton, with blunt leaves growing in clusters—Dark-green-leaved—Villose hoary-leaved, with a large flower.

The above two shrubby Lavender Cottons, and varieties, are retained in our gardens, both as plants of ornament and for medicinal use, the leaves, flowers, and seeds being proper, particularly the first species.

Herbaceous kinds.

³SANTOLINA *Anthemoides*.

Anthemis-leaved Lavender Cotton.] Hath fibrous perennial roots, herbaceous, very branchy, hairy stalks, eight or ten inches high; bipinnated, many-parted downy leaves

S A P

Leaves like those of chamomile, and the branches terminated by long pedunculi, each sustaining one compound yellow flower.

⁴*SANTOLINA Alpina.*

Alpine Lavender Cotton.] Hath fibrey perennial roots, herbaceous unbranching stalks eight or ten inches high, bipinnated grey leaves, and pedunculi terminated by one yellow flower.

The two shrubby species and varieties, being hardy, low, bushy ever-greens, are proper ornamental plants for adorning the fronts of small shrubbery compartments, where, with their hoary, and lighter and darker-green leaves, in different varieties, they will exhibit an agreeable variety. Some may also be potted, to move occasionally, to embellish any particular compartment in assemblage.

The herbaceous kinds being also hardy, are likewise employed occasionally to cause variety in the pleasure ground.

Method of Propagation.

The shrubby kinds are propagated the most expeditiously by slips or cuttings of the young shoots, and may also be raised from seeds.

By Slips, or Cuttings.—In spring, or early in summer, slip or cut off a quantity of the last year's shoots, five or six inches long, clear away all the lower leaves, then plant them in any shady border in rows half a foot asunder, water them directly, and repeat it in dry weather, and they will root freely and form tolerable plants by autumn, when, or in the following spring, they may be transplanted with balls, in wider nursery-rows, &c. or some of the largest where they are finally to remain.

By Seed.—Sow it in the spring, in a bed of light earth, either in shallow drills or all over the surface, covering it a moderate depth; they will grow the same year, and towards autumn, or in the next spring, prick them out half a foot asunder, and after having a year's growth they must be transplanted to wider distances.

The two herbaceous kinds are propagated by parting the roots in autumn; and by seed in the spring, sowed in any common earth and raked in, and when the seedlings are a little advanced in growth plant them out.

SAPONARIA, Sope-wort.

The plants are herbaceous perennials and annuals, of hardy temperature, some of the former being cultivated as flowering plants

S A T

for variety, &c. producing annual stalks two or three feet high, terminated by bunches of pentapetalous flowers.

Class and order. *Decandria Digynia.*

Characters.] *CALIX*, is monophyllous, tubular, quinquedentate and permanent.—*COROLLA*, five petals, narrow and angular below, and broad, obtuse, and plane above.—*STAMINA*, ten awl-shaped filaments, inserted alternately into the ungues or tails of the petals, having long incumbent antheræ.—*PISTILLUM*, a taper germen, two parallel styles crowned with acute stigmas.—*PERICARPIUM*, a cylindric, covered, unilocular capsule, having many small seeds.

There are several species, one of which only is common to the English gardens, viz.

SAPONARIA Officinalis.

Common Sope-wort.] Hath a creeping, very spreading, perennial root, upright-jointed stalks two feet high or more, garnished with oval-lanceolate opposite leaves, and the stalks terminated by umbel-like bunches of purplish flowers.

Varieties.] Common Single-flowered Sope-wort—Double-flowered—Hybrid Sopewort with concave leaves.

This species grows wild in England, but is sometimes retained in gardens for variety, particularly the Double-flowered and Hybrid concave-leaved sort; they all succeed in any common soil, are durable in root, which send up stalks annually in the spring, and flower in July, continuing in succession till September,

The root and leaves are used in medicine; and the leaves were formerly used instead of Sope, and by being boiled in water afford a sope-like froth, proper for washing cloaths; hence the name Sope-wort.

These plants are easily propagated by parting the roots, any time in open weather, from autumn till spring.

SATUREJA, Savory.

This genus is composed of low, under-shrubby, and herbaceous aromatic perennials and annuals, for the kitchen-garden, pleasure ground, and green-house, ornamented with small narrow leaves, and small monopetalous ringent flowers at the sides and termination of the branches.

Class and order. *Didynamia Gymnospermia.*

Character.] *CALIX*, is monophyllous, erect, tubulous, striated, five-parted at top, and permanent—*COROLLA*, is monopetalous, and ringent, with a cylindric tube, and simple chaps, having the upper-lip acutely emarginated,

ginated, and the under-lip three-parted. — STAMINA, two long and two short filaments, crowned with connivent anthers. — PISTILLUM, a quadrifid germen, a bristly style, having two bristly stigmas. — PERICARPIUM, none, four roundish naked seeds lodged in the permanent calix.

There are eight or nine species; the following six of which are the sorts principally known in our gardens, being all exotics from different countries; three of which are hardy, and the others tender, requiring shelter of a green-house in winter.

Hardy kinds.

Consists of three species; two low under-shrubby, and herbaceous perennials, and one annual; all of the aromatic tribe; two of which, Winter Savory and Summer Savory, are eminent pot-herbs, for the kitchen-garden and for medical use.

¹SATUREJA *Montana*. (Perennial.)

Mountain Satureja, commonly called Winter Savory.] Rises with a low shrubby stem, branching numerously about a foot high; closely garnished with small linear-lanceolate leaves, many together at the joints; and at the sides of the branches, short-forked peduncles, supporting small whitish-red flowers.

This is a fine aromatic perennial, durable in root, stem, and branches, and continues in leaf the year round.

²SATUREJA *Virginiana*. (Perennial.)

Virginian Savory.] Rises with upright, stiff, angular stalks, branching a foot and half high; small spear-shaped, pointed, stiff leaves, scented like penny-royal; and the branches terminated by white flowers in round heads.

³SATUREJA *Hortensis*. (Annual.)

Garden Satureja, or Summer Savory.] Rises with upright slender stalks, branching by pairs a foot or more high; narrow, spear-shaped, stiff, odoriferous leaves, and from the sides of the branches pale-red flowers, two on each peduncle.

This is a choice aromatic annual pot-herb for the kitchen-garden.

Green-house kinds.

They consist of three low, under-shrubby, ever-green, aromatic perennials, exotics from warm countries, and require shelter here in winter.

⁴SATUREJA *Juliana*.

St. Julian's Thymbra, or True Savory] Rises with erect, slender, ligneous stalks, branch-

ing moderately nine or ten inches high; narrow, spear-shaped, finely-scented leaves, and small white flowers, in whorled bunches, round the branches.

⁵SATUREJA *Thymbra*.

Legitimate Thymbra.] Rises with shrubby stems, branching about two feet high; oblong, acute, odoriferous leaves, and reddish flowers, in thick hispid whorls round the branches.

⁶SATUREJA *Capitata*.

Capitated Savory, or Legitimate Thyme.] Rises with shrubby long stalks, branching eight or nine inches high; narrow, carinated, punctated, ciliated leaves, and the branches terminated by capitated spikes of white flowers.

All these plants flower in June and July; the flowers are small, and each formed of one ringent petal, and in some sorts are succeeded by seeds in our gardens, particularly the Winter and Summer Savory.

With respect to the three hardy species, the two first are perennial, and the third is annual; are all hardy enough to succeed in the open ground; the first and third sort merit culture, in every kitchen-garden, as aromatic pot herbs and as medical plants; and all the three sorts may also be employed to diversify the compartments of the pleasure garden, &c. allowing them generally a dry soil.

And the tender kinds, requiring shelter from frost, must be kept in pots, and placed among the green-house exotics, where they will encrease the variety, managing them as other shrubby exotics of that collection.

Method of Propagation for all the Sorts.

The three hardy sorts are propagated, some by seed, and the two perennials also by slips or cuttings of the branches, and by parting the roots.

By Seed.—The Winter and Summer Savory furnish plenty of seed annually in autumn, by which they may be raised in abundance, sowed in the open ground in spring; therefore, in the latter end of March, or in April, dig a bed or border of light rich earth, and sow the seed thereon moderately thick, and rake them in evenly, they will soon come up; being then careful to give occasional weeding, and if the plants are any where too much crouded, thin them moderately, and they may either remain where sowed, thinning them to due distances, or may be transplanted.

(Observe,

Observe, however, of the Winter Savory, that when the seedlings are about two or three inches high, it is eligible to plant out a quantity of the strongest, in moist weather, in nursery-rows six inches asunder, to remain till September or spring following, then to be transplanted with balls where they are finally to remain, in rows a foot asunder.

But the annual or Summer Savory, may either remain where sowed, thinning the plants to six or eight inches distance; or when two inches high, a quantity may be pricked out in beds, in rows the above distance; in either case the plants will become useful in June or July until winter, when they will totally perish.

Or, when designed to have the Winter or Summer Savory remain where sowed, the seeds may be sowed in shallow drills, either in beds, or along the edge of any bed or border by way of an edging.

By Slips, &c.—In the spring, or early part of summer, the common Winter Savory may be increased plentifully by slips or cuttings of the young shoots or branches, which very freely take root; therefore, slip or cut off a quantity of young shoots five or six inches long, plant them with a dibble, in any shady border, in rows six inches asunder, giving occasional waterings, and they will be well rooted by September, when they may be transplanted with balls when wanted; those for the kitchen-garden plant in rows a foot asunder, or may be planted in rows along the edge of any border, or other compartment, by way of an edging, as before observed of the seedlings.

By parting the Roots.—The Virginian Savory, in particular, may be propagated in plenty by parting the roots in autumn or spring.

The three tender kinds are very easily propagated by slips or cuttings in May, June, or July, chusing some of the most robust young side-shoots, slipping or cutting them off, and plant them in pots, several in each, which, if plunged in a hot bed, will greatly facilitate their rooting, or, in default thereof, place them under a frame and lights, or ha d-glasses, shading them from the sun, and give water, they will soon show signs of growth, when let them enjoy the free air, and, when well rooted, towards autumn transplant them in separate pots.

As these kinds are apt to dwindle off in three or four years, it is therefore proper to

continue raising a fresh supply of new plants accordingly.

SAXIFRAGA, *Saxifrage*.

This genus comprehends many low, hardy, herbaceous perennials; some of which producing ornamental flowers, are proper for the decoration of the pleasure ground, rising mostly with annual stalks, some a foot high or more, others not so much, adorned with small lobated and entire leaves, and terminated with small pentapetalous flowers.

Class and order, *Decandria Digynia*.

Characters.] CALIX, is short, monophyllous, five-parted, and permanent.—COROLLA, five potent petals.—STAMINA, ten awl-shaped filaments, with roundish antheræ—PISTILLUM, a roundish acuminate germen, two short styles and obtuse stigmas.—PERICARPIUM, an oval, birostrated, or two-beaked, unilocular capsule, containing numerous small seeds.

There are upwards of thirty species of this genus, but not more than five or six that are esteemed for general culture, which are considered generally as flowery plants, for variety in the pleasure-ground, as aforesaid.

The principal species are,

¹SAXIFRAGA *Granulata*.

Granulous-rooted, Common White Saxifrage.]

Hath a granulous perennial root, being composed of numerous small tuberous parts like grains of corn, crowned with many small, kidney-shaped, lobated leaves, upright branchy stalks a foot high; garnished also with kidney-shaped leaves, and terminated by tufted bunches of numerous white flowers.

Varieties.] Common Single-flowered of the meadows—Double flowered of the gardens, being very ornamental.

They flower in April and May, which, when in large tufts, as many stalks rise close together, they make a very ornamental appearance, particularly the Double-flowered variety, and may be disposed either in patches, towards the fronts of borders, or in pots.

²SAXIFRAGA *Cotyledon*.

Cotyledon Saxifrage, with a paniculated and pyramidally branching stalk.] Hath a thick, fibrated, perennial root, crowned with tongue-shaped cartilaginous-sawed leaves, in an aggregate cluster like house-leek, an upright paniculated branching stalk, a foot or more high, having all the branches terminated by panicles of white flowers.

Varieties.] Common Paniculated Cotyledon Saxifrage—Pyramidal Saxifrage, branching

branching almost from the bottom a foot and half high, with the branches diminishing gradually in length upward, and all of them terminated by spreading white flowers; the whole forming a beautiful pyramid.

³*SAXIFRAGA Umbrosa.*

Umbrose Saxifrage, commonly called London Pride, or None-so-pretty.] Hath a fibrated perennial root, crowned with ob-oval nearly retused leaves in circular heads, having cartilaginous crenated margins; and upright, slender, naked, paniculated stalks a foot or more high, terminated by panicles of whitish flowers spotted with red, having also red pistils.

This is an old inhabitant of our gardens, and was formerly planted for edgings, though it is rather improper for that purpose, but being disposed in tufts about the borders, it will effect a proper variety.

⁴*SAXIFRAGA Hypnoides.*

Cushion Saxifrage, commonly called Lady's Cushion.] Hath a fibrated perennial root, crowned with narrow trifid leaves, many trailing spreading shoots, garnished with entire and trifid leaves, and upright, almost naked stalks, but a few inches high, terminated by small bunches of whitish flowers.

The trailing shoots and leaves of this plant forming a close roundish bunch like the shape of a cushion or pillow, hence it is commonly called Lady's Cushion.

⁵*SAXIFRAGA Punctata.*

Spotted Saxifrage.] Hath a fibrous perennial root, crowned with roundish indented leaves, in a circular cluster, on long foot-stalks, and upright, slender, naked stalks a foot high, terminated with panicles of white flowers spotted with red punctures.

⁶*SAXIFRAGA Hirsuta.*

Hairy Saxifrage.] Hath a fibrous perennial root, crowned with heart-shaped-oval retuse leaves, with cartilaginous-crenated edges, and hairy leafless stalks, near a foot high, terminated by panicles of white flowers, having a few red spots.

These six species are all hardy perennials, generally considered as flowery plants; but the first three sorts are the most commonly cultivated, and have the greatest merit as plants of ornament; however, all the sorts may be employed for variety, and disposed in patches towards the fronts of flower-borders, &c. and the first and second sort are also often planted in pots to move to any place occasionally, more particularly the Granulous Double White Saxifrage, and the

Cotyledon Pyramidal Saxifrage, both of which demand singular attention for their ornamental flowers.

They are all durable in root, and some sorts also retain their leaves all the year; the Granulous Saxifrage, however, is deciduous, and all the sorts produce flower-stalks annually in the spring, flowering, in the different sorts, from April till June; the first species and variety generally flower in April and May, and the others in May and June.

All the sorts are very easily propagated by off-sets of the roots and heads, which they furnish abundantly.

The first sort multiplies exceedingly by its granulous roots, which, towards autumn, when their stalks and leaves decay, may be divided, not too small, but in little bunches, and let them be planted again directly, some in the open borders, &c. and some in pots, forming a small hollow in the earth an inch deep, in which deposit the bunch of roots, covering them the same depth with earth; and being thus planted in bunches, they will send up several stalks in a cluster together, and exhibit a large tuft of flowers.

The second and third species multiply very fast by side off-sets from the head or crown of the plant, each furnished with roots, which may be parted or separated in autumn, or early in the spring, and planted where they are finally to remain, observing to plant some of the Cotyledon pyramidal sort in pots, and the others in patches towards the front of the borders.

The other three sorts are also propagated by off-sets, and parting the roots, in autumn or spring.

SCABIOSA, Scabious.

This genus of plants consists of herbaceous annuals, biennials, and perennials, for ornament and variety in the pleasure-ground, and shrubby perennials for the green-house, garnished with leaves of different forms in the different species, and terminated with numerous aggregate heads of flowers, each head composed of many small florets contained in one general calix.

Class and order, *Tetrandria Monogynia.*

Characters.] CALIX, a spreading many-leaved general cup, containing many florets, each floret having a double calix.—COROLLA, each floret of the aggregate is monopetalous, tubulous, and cut into four or five parts at top.—STAMINA, four awl-shaped filaments in each floret, having oblong incumbent

eumbent antheræ.—PISTILLUM, a germen under each floret, and a slender style, crowned with an obtuse, obliquely emarginated stigma.—PERICARPIUM, none; a single, oblong, oval seed to each floret crowned with the calix.

There are many different species of Scabiosa; a few only are in esteem for general culture, principally as plants of ornament and variety, consisting of some hardy herbaceous annuals, biennials, and perennials; and three shrubby exotics for the green-house.

Hardy herbaceous kinds.

This head comprehends some remarkable flowery annuals and biennials, and some perennials for variety, rising with upright branchy stems, two or three feet high or more, garnished with leaves below, and numerous flowers at top; observing, the first two are annuals, the rest perennial; but the annual kinds are the most generally known, and cultivated as ornamental plants.

¹SCABIOSA *Atropurpurea*. (Annual, &c.)

Dark-Purple Sweet Indian Scabious.] Hath a fibrous annual root, crowned with a large tuft of oblong leaves, variously jagged and cut on the edges, and often into segments, and upright stems, branching numerously, on every side, three feet high or more; and from the sides and ends of the branches, numerous dark-purple, and other coloured flowers, in the varieties, having all quinquefid florets and awl-shaped receptacles.

Varieties.] Common Dark-purple Sweet Scabious — Pale-purple-flowered — Red-flowered — White-flowered — Black-flowered — Hen and Chicken-flowered, having several small flowers arising from the sides of the main one — Striped-flowered, &c.

They all flower in June, continuing in plentiful succession till September, forming a very ornamental appearance, and are succeeded by abundance of ripe seeds in autumn.

All the varieties of this species are very hardy, and may be considered both as annuals and biennials, for, being raised from seed forward in the spring, they will run up to stalk and flower the same year, and generally perish the following winter; but if not sowed till summer, they produce only leaves that year, encrease in strength, and remain vigorous till spring following, when they will shoot up vigorously into very strong branchy stems, and produce an amaz-

ing quantity of flowers from June till autumn, and furnish plenty of seeds, then totally perish root and stem towards winter, so that a fresh supply must be annually raised from seed both as annuals and biennials.

²SCABIOSA *Stellata*. (Annual, &c.)

Starry Spanish Scabious.] Hath a fibrous annual root, crowned with oblong leaves, variously cut on the edges, and upright stems branching numerously about a yard high, garnished with oblong, finely cut leaves, and the upper parts supporting numerous purple flowers composed of quinquefid star-shaped florets with roundish receptacles, flowering in July.

This sort may also be treated both as an annual and biennial, as observed of the former sort; but more commonly as an annual.

³SCABIOSA *Arvensis*.

Common Field Scabious.] Hath fibrous perennial roots, upright hispid stems, branching three feet high, garnished with pinnatifid leaves, with the lobes at a distance, and blue flowers, having radiated florets.

Varieties.] With reddish flowers—Purple-flowered, &c.

It grows wild in the fields and meadows in England, but is sometimes cultivated for variety.

⁴SCABIOSA *Succisa*.

Succisa, or Devil's Bit (Morsus Diaboli.) Hath a thick, short, downright root, terminated abruptly as if bit off, crowned with oval, spear-shaped, entire leaves; upright single stalks two feet high, with the branches growing near, and terminated by blue flowers with equal quadrifid florets.

This grows naturally in England, &c. in pastures and woods.

⁵SCABIOSA *Alpina*.

Alpine Blue Scabious.] Hath a strong, fibrous, perennial root, sending up several strong stems, branching four or five feet high, garnished with pinnated leaves of four or five pair of spear-shaped sawed lobes; and from the upper parts, whitish-yellow drooping flowers, having quadrifid equal florets.

⁶SCABIOSA *Argentea*.

Silvery Oriental Scabious.] Rises with low slender stems, dividing into spreading branches, pinnated silvery-white leaves, with spear-shaped lobes, and the branches terminated by long, naked, smooth peduncles, sustaining small pale flowers with quinquefid florets.

⁷SCABIOSA *Gramina*.

Grass-leaved Silvery Scabious of the Helvetic Mountains.] Hath a fibrous perennial root, sending up herbaceous stalks half a yard high, garnished below with very narrow, lanceolate, entire silvery leaves; and the upper part supporting pale-blue flowers, having quadrifid florets.

All these herbaceous kinds are very hardy plants, that succeed in any common soil of a garden, and in almost any situation.

But the two annual sorts are the most generally known and cultivated, and have the greatest merit as ornamental flowery plants.

Tender Shrubby kinds for the Green-house.

Comprises three shrubby species, exotics from warm countries, as mentioned in their titles, and require shelter here in winter, so must be kept in pots and placed among the green-house plants.

*SCABIOSA *Cretica*.

Cretan Shrubby Scabious.] Rises with a shrubby stem, branching two or three feet high; long, spear-shaped, whitish, entire leaves, numerous in clusters, and the branches terminated by fine blue flowers, having quinquefid florets.

Variety.] Auricula-leaved.

*SCABIOSA *Africana*.

African Shrubby Scabious.] Rises with a shrubby stem, branching four or five feet high; oval-spear-shaped cut leaves, and the branches terminated by flesh-coloured flowers, having quinquefid florets.

Varieties.] Rough crenated-leaved—Finely cut-leaved—Woolly-leaved.

*SCABIOSA *Rigida*.

Rigid or Stiff-leaved Shrubby Ethiopian Scabious.] Rises with a shrubby stem, branching two or three feet high; spear-shaped, serrated, stiff, shining leaves, and the branches terminated by whitish flowers, having quadrifid, nearly-radiated florets, and obtuse calicinal scales.

All the above species of *Scabiosa* flower commonly in June, July, and August, and some continue in succession till autumn, generally producing the flowers upon long foot-stalks singly, each flower being an aggregate of several small quadrifid or quinquefid florets, placed all within one common calix, forming together a moderately large flower, which, in some species, are prodigiously numerous, and very ornamental, particularly the two annual kinds; and which

two sorts furnish plenty of seeds in autumn, likewise most of the other species.

The merit of these plants is, some for ornament others for variety.

The two annual kinds, in particular, producing abundance of ornamental flowers, very conspicuously, two or three months in summer, are choice furniture for all the common flower compartments, and merit culture in every garden; being raised annually from seed in spring and summer, in the open ground, and thence planted out to remain to flower, which, in those of the spring sowing, will be effected the same year, but those raised in summer do not flower till the summer following.

The herbaceous perennial kinds may be introduced in the compartments of large gardens for variety.

And the shrubby kinds, being potted and placed among the green-house exotics, they will effect a good variety, and flower ornamentally in summer.

Propagation and Culture of all the Sorts.

First, the Annual and Biennial Sorts.—The two first species, being hardy annuals and biennials, may be raised plentifully from seed annually, in a bed or border of common earth, and, as formerly noticed, may be considered both as annuals and biennials, and may be treated accordingly, more particularly the *Scabiosa Atropurpurea* and varieties; observing, that if intended to raise them as annuals, for flowering the same year, they should be sowed in the spring, about March, on a warm border, or, to bring them as forward as possible, may sow them in a hot-bed; and being planted out about the borders, in May or beginning of June, they flower the same year in July or August, though not near so strong as plants raised the year before as biennials: therefore, in order to have strong flowering plants, it is most eligible to sow a principal share in June, to encrease in growth all summer without running up to stalks, and stand the winter, for flowering early next summer, in which they will produce much stronger stems, branching more numerous and strong, and produce a greater number of flowers: however, it may be proper to sow both in spring for flowering the same year, and in June for next year's flowering; but it is more particularly proper to sow some of the *Starry Scabious* in spring as annuals.

Observe,

Observe, in sowing these two annual sorts, that the first sort in particular may be sowed for transplantation, chusing a bed of light moist earth; sow the seed evenly and rake it in; and when the plants are two or three inches high, prick out some of the strongest, in moist weather, where they are to remain to flower, especially the spring-sowed plants; but those designed for next year's flowering should be planted in nursery-beds, in rows six or eight inches asunder, giving necessary waterings and weeding, and they will grow fine large plants by autumn, when, or in the following spring, transplant them with balls of earth to the places where they are to flower.

But the Starry Scabious may either be sowed in spring for transplantation, or in patches about the borders, to remain where sowed, to flower.

Perennial Sorts.—The five hardy, herbaceous, perennial Scabiouses, are all very easily propagated, both by seeds sowed in any bed or border of common earth in the spring, and the seedlings planted out where they are to remain, and by parting the roots in autumn.

Shrubby kinds.—All the three shrubby sorts are expeditiously propagated by planting slips or cuttings of the branches in spring or summer; if in spring, plant them in pots, and place them either in a hot-bed or under shelter of glasses; but in summer they may be planted in the full ground, shaded and watered; and in either method they will root tolerably well the same year, and towards autumn may be potted off separately, and managed as other shrubby exotics of the green-house.

SCANDIX, Shepherd's Needle, Garden Chervil, &c.

This genus is composed of herbaceous annuals and a perennial, for the kitchen-garden and for variety, rising with finely-divided leaves, and erect stalks from one to four or five feet, terminated by umbels of flowers.

Class and order. *Pentandria Digynia*.

Character.] CALIX, umbellate flower; the general umbel long, and composed of a few rays, and the partial umbels of many, and the smaller umbellæ only have a five-leaved involucre—COROLLA, a deformed, radiated, general umbel, having both hermaphrodite and female florets, composed of five heart-shaped petals.—STAMINA, five slender filaments with roundish antheræ.—PISTIL-

LUM, an oblong germen, two permanent styles and obtuse stigmas—PERICARPIUM, none, a long two-parted fruit, having two awl-shaped furrowed seeds.

There are seven or eight species, one of which only is common to the English gardens, known by the name of Garden Chervil, a fine aromatic, esteemed as a salad and soup herb. There is also a perennial sort sometimes cultivated for variety.

¹SCANDIX *Cerifolium*. (Annual)

Cerifolium, or *Garden Chervil*.] Hath a fibrated annual root, crowned with many finely-divided leaves, of an aromatic flavour, and upright stalks, one or two feet high, terminated by umbels of white flowers, with lateral umbels sitting close, succeeded by oval, awl-shaped, shining seeds.

This is an annual plant, but remains in leaf all winter, and is cultivated as a culinary herb for winter and spring service; it may also be continued for use the year round, by sowing several times from February till September, because the spring and summer sowing run up to seed the same year, but the autumn sowing will remain green until spring before it runs.

²SCANDIX *Odorata*. (Perennial.)

Odoriferous, *Great*, *Perennial Chervil*, or *Sweet-fern*.] Hath a thick, fibrated, perennial root, of a sweet aromatic taste, crowned with large divided leaves, resembling fern, and upright hollow stalks, four or five feet high, terminated by large umbels of white, very fragrant flowers, succeeded by long, angular, furrowed seeds.

These plants are both very hardy; the first is an annual, and the other a perennial. The annual sort is in estimation both for salads and soups, as before observed, and the leaves are the useful part; the young leaves of the second were also sometimes used formerly, but rarely now, so is only retained in some gardens to encrease the variety in the pleasure ground, and the annual sort for the kitchen-garden only, which will grow in any soil and situation.

They run up to stalk in spring, flower in May or June, and the seeds ripen in July.

As to the culture of the *Cerifolium*, or *Garden Chervil*, it is by seed annually, observing, if it is required most part of the year, the sowing should be continued every month till August or September, as before hinted; but if required only for winter and early spring use, an autumn sowing in August or begin—

beginning of September, will be sufficient, and the plants coming up soon after remain useful from October till March or April. The seed may be sowed any where, either broad-cast and raked in, or in shallow drills six or eight inches asunder; and in either case the plants are to remain where sowed, being careful to give occasional weeding, which is all the culture they require, and they will soon be fit to cut for use.

The second may also be raised from seed, and plant out some of the plants about the large compartments, and when once thus raised they will remain several years, and from its scattered seeds many young plants will rise in the adjacent ground.

SCHINUS, Indian Mastic tree.

It consists of two shrubby ever-green exotics for the green-house and stove, rising eight or ten feet high, adorned with pinnated many-lobed leaves, and the branches terminated by bunches of pentapetalous flowers.

Class and order. *Diœcia Decandria*.

Characters.] **CALIX**, dioecious flowers, having monophyllous, acutely five-parted cups, that of the females being permanent.—**COROLLA**, five oval petals in the males, and five oblong ones in the female flowers; those in both sexes being petiolated.—**STAMINA**, ten filiforme spreading segments, having roundish antheræ.—**PISTILLUM**, a roundish germen, no style, but three oval stigmas.—**PERICARPIUM**, a globular trilocular capsule, having three seeds.

There are only two species, which being natives of Peru, and other parts of the Indies, require shelter of a good green-house here in winter, so must always be kept in pots.

¹**SCHINUS Molle**.

Molle-tree of Clusius, or Peruvian Mastic-tree.] Rises with a woody stem, branching numerously eight or ten feet high, with pinnated leaves of ten or twelve pair of sawed lobes and an odd one, which is much the longest; and the branches terminated by loose bunches of whitish flowers.

²**SCHINUS Areira**.

Areira, or Brazilian Mastic-tree.] Hath a woody stem, branching eight or ten feet high, with pinnated leaves of ten or twelve pair of entire lobes, and an odd one, all of equal length; and at the sides and ends of the branches small clusters of whitish flowers.

Both these species are shrubby, durable in root, and top, and retain their leaves the year round; and being natives of hot coun-

tries, require shelter here of a good green-house in winter; or, if sheltered in a stove, two or three winters whilst young, it will be an advantage to the plants; however, they both succeed tolerably with the culture of common green-house exotics. They being pretty ever-greens, with finely pinnated leaves, merit a place in the collection of our tender exotics, in which they will effect a good variety; let them, therefore, be cultivated in pots of rich earth, and placed among the plants of the above department.

They are propagated by seed obtained from abroad, also by layers and cuttings.

Sow the seeds in the spring, in pots of rich earth, and plunge them in a hot-bed, managing them as other tender seedling exotics.

Layers of the young branches in the spring will be well rooted in one year.

And cuttings of the young shoots, planted in spring, in pots, and plunged in a hot-bed, will readily emit roots in six or eight weeks.

SCILLA. Squill, or Sea-Onion, Starry Hyacinth, &c.

This genus comprehends a fine collection of hardy, bulbous-rooted, flowery perennials, for adorning the flower borders, having mostly very large tunicated and solid bulbous roots, crowned with long narrow leaves, and erect flower stalks, annually; in some sorts two or three feet high, in others but a foot, and some but six or eight inches, ornamented at top with pyramidal and conic clusters of hexapetalous starry flowers.

Class and order. *Hexandria Monogynia*.

Characters.] **CALIX**, no cup.—**COROLLA**, six oval petals, spreading out like the figure of a star.—**STAMINA**, six awl-shaped filaments, crowned with oblong, incumbent antheræ.—**PISTILLUM**, a roundish germen, simple style, and single stigma.—**PERICARPIUM**, a nearly oval, three furrowed, trilocular, trivalved capsule, containing many roundish seeds.

There are about eight species, all of the bulbous-rooted tribe, seven of which are originally from distant countries, as Spain, Portugal, France, &c. and the eighth grows wild in some parts of England, &c. and all the sorts are hardy enough to succeed in our gardens in the full ground.

¹**SCILLA Maritima**.

Maritime Squill, or Common Sea Onion.]

Hath a large oval tunicated onion-like bulbous root, sending up long narrow leaves, near half a yard in length, and an upright

right naked stalk, two or three feet high, having the upper half adorned with a pyramidal thyse of white starry flowers appearing early in summer.

Varieties.] Red-rooted—White-rooted.

This species is a maritime plant, inhabiting the sandy sea-shores of Spain and other warm countries, but the bulbs are sent here annually for medical use, and are planted in many gardens as flowery plants for curiosity.

²*SCILLA Lilio-Hyacinthus.*

Lily Hyacinth.] Hath a squamous, or scaly, bulbous, lily-like, yellow root, crowned with oblong lily-like leaves, half a foot long or more, and an upright slender stalk, about a foot high, terminated by many star-shaped blue flowers, appearing in June.

³*SCILLA Peruviana.*

Peruvian Hyacinth, or Hyacinth of Peru.] Hath a large, oblongish, bulbous brown root, sending up several carinated spreading leaves, six or eight inches long, broad at the base, decreasing to a point at top, and upright, thick, succulent stalks, six or eight inches high, terminated by a conical corymbus cluster of deep-blue starry flowers, appearing in May.

Variety.] With white flowers.

⁴*SCILLA Italica.*

Italian, Blue-spiked, Starry Hyacinth.] Hath a roundish, white, bulbous root; longish leaves with obtuse points, and erect stalks, eight or ten inches high, terminated by a hemispherical corymbus of pale-blue flowers, appearing in April.

⁵*SCILLA Amoena.*

Fine Byzantine Hyacinth.] Hath a large, roundish, bulbous, purplish root, sending up several narrow, carinated, spreading leaves a foot long, and upright purplish stalks eight or ten inches high, ornamented upward with fine sky-blue somewhat drooping flowers, rising laterally in alternate order, appearing in March or April,

⁶*SCILLA Bifolia.*

Two-leaved Early Star Hyacinth.] Hath a small, roundish, solid, bulbous root, sending up only two narrow leaves, about six inches long, and a slender stalk half a foot high, terminated by a few, nearly-erect, blue, starry flowers, appearing early in March.

Variety.] With white flowers.

⁷*SCILLA Autumnalis.*

Autumnal Squill, or English Starry Hyacinth.] Hath a small, round, white, bulbous root, very slender linear leaves, six inches long,

and upright slender stalks, half a foot high, adorned at top with a corymbus of small, blue, starry flowers, having naked peduncles, rising over one another, the length of the flower, appearing early in September. This grows naturally in many parts of England, &c.

All these species of *Scilla* are bulbous perennials, durable in root, but annual in leaves and stalks, which rise immediately from the root: in some sorts the leaves spring up in autumn, and remain green all winter, and decay in spring, particularly the first, third, and last sort, and some others: and in some the leaves and flower-stalks appear at the same time. The stalks are generally naked or leafless, and terminated by the flowers, which consist universally of six oval petals, spreading open, in a star-like manner, with great uniformity and beauty, exhibiting a good ornamental appearance; and in most of the sorts are succeeded by ripe seeds in autumn, by which all the sorts may be raised; but more expeditiously by off-sets of the roots annually, when the leaves and stalks decay.

They being all of hardy temperature, may be employed as flowery plants to adorn the pleasure ground, disposed either in patches about the borders, &c. or deposited in beds by themselves.

Observe, they should generally be removed for transplantation when their leaves and flower-stalks are decayed, when the roots may be taken up, and either planted again directly, where wanted, or kept till autumn, &c. though the autumnal sort should be planted early, in order that they may blow the same year in autumn; planting all the sorts about three or four inches deep, or in proportion to the size of the bulb. See BULBUS.

The bulbs of all the sorts may be had, moderately cheap, at most of the nursery-grounds and seed-shops.

Method of Propagation, &c.

The propagation of all the sorts is by off-sets of the roots; the first species, however, being a native of sandy sea-shores, it encreases but sparingly in gardens, but is obtained plentifully from abroad. All the others furnish plenty of off-sets, which may be separated every other year, if required, when their leaves, &c. decay, as practised for other bulbous roots.

They

They may all be propagated also by seed, though this is a tedious method, as the seedlings are several years before they blow: they should be sowed in autumn, in light earth, an inch deep, observing, the same method of sowing and culture practised for the Common Hyacinths, &c. See HYACINTHUS.

SCORPIURUS, Caterpillar.

The plants of this genus are hardy, herbaceous, trailing annuals, cultivated in the pleasure ground more as plants of singularity than beauty, for the oddity of their caterpillar-like seed-pods; they rising with procumbent stalks, garnished with oblong simple leaves, and papilionaceous flowers, succeeded by contorted pods resembling green caterpillars.

Class and order, *Diadelphia Decandria*.

Characters.] CALIX, is monophyllous, inflated, and cut into five acute segments.—COROLLA, is papilionaceous; the standard, roundish, emarginated, spreading, and reflexed; the wings are loose and nearly oval, and a semi-lunulated, pointed, erect keel, two-parted below.—STAMINA, ten diadelphous filaments, with small antheræ.—PISTILLUM, an oblong taper germen, a rising inflexed style, terminated by a punctura or point.—PERICARPIUM, an oblong, coriaceous, revolute, rough pod, of many transverse cells, each containing one seed.

There are four species, natives mostly of the south of Europe, but grow freely here, in our gardens, in the open borders.

The species are,

¹SCORPIURUS *Vermiculata*.

Common, Vermiculated, Uniflorous Caterpillar.] Rises with trailing herbaceous stalks, a foot or more long, garnished with oblong spatula-shaped leaves; and at the axillas long pedunculi, each supporting one papilionaceous yellow flower, succeeded by oblong twisted pods, covered on every side with obtuse scales.

²SCORPIURUS *Muricata*.

Muricated Biflorous Caterpillar.] Rises with thick-trailing, herbaceous stalks, a foot and half long, garnished with oblong, broad, obtuse leaves, and at their axillas long pedunculi, each sustaining two papilionaceous yellow flowers, succeeded by oblong, very twisted, rough pods, having the outside armed with obtuse oculi.

³SCORPIURUS *Sulcata*.

Sulcated Triflorous Caterpillar.] Rises with slender, trailing, herbaceous stalks, a foot

long, oblong obtuse leaves, and each peduncle supporting three yellow flowers, succeeded by slender moderately-twisted pods, armed on the outside with acute distinct spines.

⁴SCORPIURUS *Subvillosa*.

Subvillose Quadriflorous Caterpillar.] Rises with trailing herbaceous stalks, a foot and half long, oblong obtuse leaves, and long pedunculi, each sustaining four yellow flowers, succeeded by oblong, slender, very contorted pods, armed on the outside with sharp spines in clusters.

All these four species of *Scorpiurus* are hardy herbaceous annuals, that rise from seed annually in the spring; are all of trailing growth, extending their stalks along upon the ground, having one leaf at each joint, and at the wings of the leaves arise the flowers, being universally papilionaceous, appearing in June and July, and are succeeded by oblong pods, variously contorted and stained, so as to bear a very great resemblance to large caterpillars, apparently feeding on the plants, effecting a curious singularity, those of the first sort in particular, which are the largest, most conspicuous, and caterpillar-like; however, all the sorts form an agreeable variety, and they all furnish plenty of ripe seeds in autumn.

These plants, therefore, merit a place in the collection of hardy annuals, principally for the singularity of their caterpillar-like seed-pods, and being disposed in patches about the borders they will exhibit an eligible variety.

They are propagated by seed in the spring, which succeeds in the full ground, and should generally be sowed in patches about the borders, where the plants are designed to remain, as they do not succeed so well by transplantation; therefore, form small patches in the different compartments, sowing several seeds in each patch, half an inch deep; and when the plants are come up an inch or two high, thin them to two or three in each place, and clear out weeds, which is all the culture they require, and they will flower in June, and exhibit their pods abundantly all the latter part of summer.

SCORZONERA, Viper's Grass, but commonly called *Scorzonera*.

The plants are herbaceous perennials, biennials, and annuals, mostly of the carrot-rooted kind, one of which, in particular, producing large eatable roots, is cultivated as a kitchen-garden esculent: they rise mostly with

with long, narrow, grassy leaves from the root, and erect tall stalks, surmounted by large compound flowers.

Class and order. *Syngenesia Polygamia Æqualis*.

Characters.] CALIX, a long, imbricated, nearly-cylindric, general cup, containing many florets.—COROLLA, many, tongue-shaped, quinque-dentate, imbricated, hermaphrodite florets, the outer ones being the longest.—STAMINA, five short filaments, having cylindric antheræ.—PISTILLUM, an oblong germen, filiforme style, and two reflexed stigmas.—PERICARPIUM, none, a single oblong seed in each floret, sitting on the receptacle within the connivent calix.

There are several species, but of which there is only one cultivated for use, as an esculent and medical plant; the others having but little merit their culture is not attended to, except in some curious botanic gardens merely for variety.

The cultivated sort therefore is,

SCORZONERA *Hispanica*.

Spanish Viper's Grass, or Common Scorzonera.]

Hath a long, downright, carrot-shaped eatable root, covered with a brown skin, but white and milky within, crowned with several long, narrow, entire, slightly-sawed leaves, terminating in a long acute point; and when it shoots for seed, runs up with an erect, robust, branchy stem, a yard or more high, garnished with amplexicaulous leaves, like the lower ones, and all the branches terminated by large, compound, bright-yellow flowers.

The root is the useful part, being in perfection in autumn and winter, and is boiled and eaten like carrots, &c. and is by many greatly esteemed.

This species, though of a perennial nature in the root, yet, for general use, it should be commonly treated as an annual or biennial; for, being raised from seed in the spring, the roots will be fit for use in the following autumn, and remain in perfection till next spring, when they will shoot up stalks for flower and seed, and become hard, sticky, and unfit for use, so should be thrown away, and a fresh supply raised from seed.

The general propagation of this plant is by seed annually, in any open light spot of ground, sowed the latter end of March or beginning of April, not earlier, lest the plants fly up to seed the same year, before the roots acquire perfection: having, therefore, made choice of an open spot of ground in the

kitchen-garden, and at the proper season digged it one good spade deep at least, then let the seed be sowed either broad-cast, all over the surface, thinly, and raked in, or may draw shallow drills, ten or twelve inches asunder, and sow the seeds therein, and rake the mould evenly over them half an inch thick; in either method the plants will rise in two or three weeks; observing, when they are a little advanced in growth, let them be thinned and cleaned from weeds, by hoeing them in dry weather, cutting out the plants to eight or ten inches distance, and cutting away all weeds between them; thus they will grow freely, and their roots continue encreasing in size till September, when they will have acquired their full size, discoverable by their leaves beginning to decay; at which token of maturity, may begin to draw them for use.

The roots may either remain in the ground, and drawn as they are wanted, or may be taken wholly up in autumn, when their leaves decay, and preserved in sand all winter, that they may be ready at all times, especially in frosty weather, when they cannot be dug out of the ground.

To save seed of this species, let some of the plants remain where sowed, when they will shoot up in the spring, and produce plenty of seed in autumn.

SEDUM, Lesser House-leek, Orpine, and Stone-crop.

This genus is composed principally of hardy herbaceous succulents for variety, rising with annual stalks, some erect, a foot or two high, some but a few inches, and some are of trailing growth; adorned with fleshy leaves, and terminated with bunches of pentapetalous flowers.

Class and order, *Decandria Pentagynia*.

Characters.] CALIX, is erect, acute, five-parted, and permanent.—COROLLA, five, spear-shaped, plane, spreading petals, and five nectariums, formed each of one emarginated scale, inserted in the outside of the germen.—STAMINA, ten awl-shaped filaments, having roundish antheræ.—PISTILLUM, five oblong germens, terminating in slender styles, crowned by obtuse stigmas.—PERICARPIUM, five acuminate spreading capsules, opening longitudinally, and are filled with many small seeds.

There are many species of *Sedum*, consisting of herbaceous perennials and annuals, inhabitants mostly of dry sterile places, as hills, rocks,

S E D

rocks, and tops of walls and buildings; and a few of the perennials only are retained in gardens for variety, and some as medical plants, most of which are succulent both in stalk and leaves; some rising with erect stalks half a yard high, others not six inches, and some trail along the ground, as above hinted, and are mostly deciduous plants, one species only being evergreen.

The most noted species are,

¹SEDUM *Telephium*.

Telephium, Common Orpine, or Livelong.] Hath a perennial root, composed of many knobbed tubercles, sending up erect, round, succulent stalks, branching half a yard or two feet high, garnished with oblong, plane, serrated, succulent leaves, and the stalks terminated by a leafy corymbus of flowers, of different colours in the varieties.

Varieties.] Purple-flowered Orpine—White-flowered—Broad-leaved.

This species is an inhabitant of woods and dry places in England, &c. but has been long a resident of gardens for variety and medical use: considered as a medicinal plant, it has great virtue in easing pains both of green wounds and old sores, the leaves being peeled or bruised, and applied to the part affected; and it is said they will also cure corns.

There is a singularity in this plant, that the stalks being cut in summer, and fastened upright in a room, they, by their succulency, will continue shooting a long time, only by sprinkling them with water once a week.

²SEDUM *Anacampseros*.

Anacampseros, or Decumbent Evergreen Italian Orpine.] Hath a fibrous perennial root, decumbent or trailing stalks, wedge-shaped entire leaves, and the stalks terminated by a corymbus of purple flowers.

³SEDUM *Rupestre*.

Rock Sedum, or Stone-crop of St. Vincent's Rock.] Hath slender, trailing, purple stalks; short, thick, awl-shaped, succulent, glaucous leaves in clusters, quinquenariouly imbricated round the stalks, and the stalks terminated by roundish cymose bunches of bright yellow flowers.

It grows naturally on St. Vincent's Rock near Bristol, and other rocky places in Europe.

⁴SEDUM *Aizoon*.

Aizoon, or Siberian Yellow Orpine.] Hath a tuberculated, fibrous, perennial root; many upright, round, succulent stalks, a foot high; lanceolate, plane, serrated, thickish leaves;

S E D

and the stalks terminated by a close-fitting cymose cluster of bright yellow flowers.

⁵SEDUM *Reflexum*.

Reflexed, Small Yellow Sedum, or Prick Madam.] Hath a slender, fibrous, perennial root; small trailing succulent stalks, garnished with thick, awl-shaped, succulent leaves sparsedly, the lower ones recurved, and the stalks terminated by reflexed spikes of bright yellow flowers.

It grows naturally on old walls and buildings in England, &c.

⁶SEDUM *Acre*.

Acrid Sedum, Common Stone-crop of the Wall, or Wall Pepper.] Hath small fibrey roots, very slender succulent stalks, four or five inches high, very small, sub-oval, gibbous, erect, alternate leaves, close together; and the stalks terminated by trifid-cymose bunches of small yellow flowers.

This sort grows abundantly on rocks, old walls, and tops of buildings, almost everywhere, which often appear covered with the flowers in summer: it merits culture in pots of rubbishy earth, and in patches in dry stony banks, and in rock-work, or on tops of walls, &c. where it will encrease into large tufts, and exhibit a pretty variety when in flower.

Its leaves, &c. are of an acrid biting quality.

⁷SEDUM *Sexangularis*.

Sexangular Stone-crop.] Hath a fibrey perennial root; thick, short, succulent stalks; small, sub-oval, gibbous, erect leaves close together, arranged six ways imbricatum, and the stalks terminated by bunches of yellow flowers.

It grows on rocky and other dry places in England, &c.

⁸SEDUM *Album*.

White Stone-crop.] Hath fibrey perennial roots; trailing slender stalks, six or eight inches long; oblong, obtuse, sessile, spreading leaves; and the stalks terminated by branchy cymose bunches of white flowers.

This grows on old walls, rocks, and buildings in England, &c.

⁹SEDUM *Hispanicum*.

Spanish Sedum.] Hath fibrous perennial roots, crowned with clusters of taper, acute, succulent leaves; slender succulent stalks, four or five inches high, garnished also with taper leaves, and terminated by downy cymose clusters of white flowers.

All

All these species of *Sedum* are hardy, herbaceous, succulent perennials, durable in root, but mostly annual in stalk, &c. which, rising in spring, flower in June, July, and August, in different sorts; the flowers consisting universally of five spreading petals, generally crowning the stalks numerously in corymbus and cymose bunches and spikes, appearing tolerably conspicuous, and are succeeded by plenty of seeds in autumn, by which they may be propagated, also abundantly by parting the roots, and by slips or cuttings of the stalks in summer; in all of which methods they readily grow and spread very fast into tufted bunches.

They being all of succulent growth, they consequently delight most in dry soils, or in any dry rubbishy earth, and most of them will grow upon rocks and buildings.

These plants merit culture for variety, but particularly the first five or six sorts, and the first sort also as a medicinal plant, indulging them generally with a light dry soil, as they are commonly the most durable in any dry rubbishy earth, either in the full ground or in pots, also in rocks, ruins, and the tops of buildings, with only a small portion of soil at first to root in.

They may therefore be disposed for variety, some in any dry or rubbishy bank or border, and some in pots of dry soil, to move to different compartments occasionally; in both cases, planting either slips of the root in the spring or autumn, or slips or cuttings of the young shoots in spring or summer, they will all readily grow and encrease fast enough; the common Orpines will also succeed in any common dry soil in any of the borders.

They may likewise be employed as rock-plants to embellish rock-work, ruins, and the like places, either planting the roots, or cuttings of the shoots, in a little mud, or any moist soil at first, and place it in the crevices, &c. they will soon root and fix themselves, and spread about very agreeably; and all the Stone-crop kinds in particular may be made to occupy the tops of walls and buildings, by planting them as abovesaid in a little mud or moist earth, previously placed on the wall, &c. they will readily root and establish themselves without farther care.

Method of Propagation for all the Sorts.

All the sorts are easily propagated by slipping the roots, at almost any time of the year; likewise by slips or cuttings of their

shoots in spring and summer, more particularly all the Orpine kinds; but cuttings of all the sorts will very readily grow; and as to the Stone-crop kinds, shoots of them may be easily slipped in spring and summer with roots to their bottom; the same may also be often practised to most of the other species: observing, in all the methods of propagation, the slips and cuttings may either be planted in the nursery way till well rooted, or planted at once where they are to remain, in the places and manner before mentioned.

They may also be propagated by seeds sowed in any dry soil, or in the crevices of buildings, &c.

SEMEN, the Seed, being the essence of the fruit of every vegetable, containing the future plant in miniature, and consists of the following essential parts.

Corculum, or Punctum Vitæ. The little heart, the point of life, or embryo of the future vegetable, being the small point or speck, placed in the center of the Seed, between the cotyledons or lobes, and attached thereto, and is distinctly visible in the bean and most other leguminous seeds: consists of two parts, the *rostellum* and *plumula*, the former being the radical or descending part that strikes downwards, and becomes the root, the other is the ascending part, that shoots upward and become the stem and branches, &c.

Cotyledon or Side Lobes. Being the side perishable lobes of the Seed, which involve, and for some time nourishes the *corculum* or embryo plant: these lobes are generally two in number, very conspicuous in the bean and other seeds of the leguminous tribe, particularly if they have been previously laid in earth or water.

After the Seeds have been committed to the earth, the *corculum* or *punctum vitæ*, begins to germinate, and the cotyledons expand, burst open the outer cover, and rises gradually out of the earth in form of leaves, commonly called the Seed-leaves, exhibiting the first visible formation of the infant plant, accompanying it for some time after its eruption from the earth, till the first proper leaves are formed in the center of the vegetable, and advanced a little in growth, then the lobes or seminal leaves becoming useless, wither and decay.

Most plants have two cotyledons or Seed-leaves, (*Dicotyledones*) particularly almost all the tribe of fibrous-rooted herbaceous plants,

and all trees and shrubs ; but some have only one cotyledon, (*Monocotyledones*) as in most of the bulbous plants of the liliaceous tribe, rising out of the ground like a sheath; and some seeds have no cotyledon at all (*Acotyledones*), such as the ferns, mosses, flags, and funguses.

Other parts of the Seed are :

Ala or Wing. Many Seeds are winged, or furnished with a thin membrane or film, and, by its flying, helps to disperse them, as in fir, birch, maple, ash, elm, hops, and numerous other sorts.

Coronula or Little Crown. Many Seeds are crowned, and some surrounded with a pappus, *i. e.* a feathery or hairy down, particularly many of the compound tribe and others, for the purpose of dissemination, being framed for flying like a shuttlecock, so as to be easily transported by the wind to very considerable distances from the parent plant; hawk-weed, groundsel, and dandelion furnish examples.

But numerous sorts of Seeds are simple, *i. e.* have neither wing nor pappus.

The number, form, size, and substance of Seeds are extremely various in different plants.

In point of number it consists of from one to several hundred, or even thousands in each seed-vessel; for some plants have only one, some two, three, four, or many Seeds, and some are of amazing fertility, amounting to many hundreds, as for instance, a single Seed-vessel of tobacco often contains about one thousand Seeds; that of white poppy, eight thousand; and the whole produce of one tobacco plant is upwards of forty thousand, though some have computed the number above three hundred thousand; and the produce of a single stalk of spleen-wort is estimated at upwards of a million of Seeds.

As to form, Seeds are either round, oval, kidney-shaped, heart-shaped, angular, &c.

With respect to size, Seeds are of numerous sizes in different plants, from the large size of cocoa nuts down to the minute Seeds of cresses, mosses, and others much smaller.

And as to substance, some Seeds are soft or fleshy, some membranous, and some are of a hard bony nature, as in all the nuciferous tribe.

Seeds are covered or naked. Covered Seeds (*Angiospermia*) are such as are contained in some vessel, either of the capsule, pod, berry, apple, or cherry kind: and naked Seeds (*Gynspermia*) are those that are not contained

in any vessel, but lodged in the receptacle, or in the bottom of the calix.

The vast variety of ways nature has provided for the dissemination of seeds is truly wonderful; in most plants the fruit or vessels, containing the seed, are raised above the ground either by erect firm stems, or often by climbing stalks, so that the fruit, being elevated from the ground, it may be more easily shaken by the wind, which often blows Seeds to a great distance; for the same reason that species of seed-vessel called a capsule, opens at the top, that the Seeds may be more easily disseminated. Many Seeds being winged, as before observed, are by that means spread far and near by the winds; these wings consisting either of a thin membrane or film, as in the fir, birch, maple, elm, ash, hops, &c. as formerly hinted; or of a fine feathered or hairy down, beard, or tail, as in most of the compound plants, also in the scabious, valerian, and many others, whereby they are easily wafted to a great distance to different soils and territories. Some seed-vessels are endued with a remarkable elasticity, by which means they dart their Seed, with an elastic force, to some considerable distance, such as touch-me-not, and spiriting cucumber, &c. Many Seeds and seed-vessels being armed with hooks, hairs, &c. by which they attach themselves to animals, and are thereby dispersed, such as in carrot, hemp agrimony, burdock, &c. Likewise Seeds of many sorts, being devoured by birds, they void them entire, often in different parts, at a distance, and they grow. Berries, and other pulpy fruit, being eaten as food, the Seeds, or kernels of many sorts often pass through unhurt, and falling to the ground often grow. Seeds are also often disseminated by rivers, torrents, and all running waters and tides, hence often conveyed many hundred leagues from their native soil, and cast upon a very different climate, to which, however, they sometimes, by degrees, render themselves familiar.

The duration of Seeds, in respect to the retention of their germinative property, is very considerable: for instance, the cucumber, melon, and gourd, often retain their vegetative power eight, ten, or twelve years; and it is said, the *mimosa* or sensitive plant, will retain the principle of life thirty or forty years; on the other hand, the greater number of seeds will not keep good above one or two years, and many will not grow well if

if more than one year old, and some Seeds require to be sowed soon after they are ripe, or they will not grow till the second year; others, unless sowed soon after they are gathered, will not grow at all, as is often the case with the coffee-berries. It is however observable, of almost all sorts of Seeds, that being sowed the first year, they generally rise sooner and stronger than older Seeds; for which reason it is advisable to chuse principally new Seeds, not more than one year old, if possible, of all sorts of plants and trees, only a few excepted, such as cucumbers and melons in particular, of which, Seeds of two or three years old, or more, are often preferable, because plants raised from new Seed are apt to run vigorously to stem without producing much fruit.

All Seeds produced in dry capsules, pods, and other dry Seed-vessels, keep much longer in their said vessels than if taken out; though it is probable that most Seeds will retain their germinative faculty longest in the bowels of the earth, when they have been accidentally buried a considerable depth out of the reach of the influence of the sun and air. And it has been observed of corn-fallad in particular, which by accident have been buried three feet deep in the ground thirty years, and the soil being turned up that depth to the top, they have grown freely; the same has also been observed of many other Seeds, which by chance have been immersed in the ground several feet deep; and in the bottom of wells, vaults, ponds, and ditches, that have not been stirred for many years, as may be judged from circumstances; for when occasion required the soil to be thrown to the top, and exposed to the sun and air, many plants have risen that had not been remembered to have been seen thereabouts before, or at least for many years past.

Likewise most sorts of Seeds, if sowed too deep, remain inactive, and some never grow at all; others, nevertheless, preserve their growing property; and when the ground is again fresh stirred, such of the Seeds as happen to be moved nearer the surface will often come up, which shews the power of the sun and free air in promoting vegetation in Seeds and plants.

Seeds, therefore, should never be sowed too deep, and always in proportion to their size; from about a quarter, or half an inch deep, for the smaller Seeds, to about one or

two inches for the middling and large kinds of Seeds. See SOWING OF SEEDS.

The germination or growth of Seeds, after being regularly sowed or committed to the earth a proper depth, is in some sorts very quick, and others slow; as for instance, cresses, mustard, turnip, and many others, come up in a few days; some other sorts in one, two, or three weeks, as in most of the esculents of the kitchen-garden; and numerous others of the herbaceous tribe, though parsley, and some others, often remain inactive a month or six weeks, and some sorts lie a year or two in the ground before they germinate. As to the tree and shrub Seeds, some will rise in a month or six weeks, or less time, others require two or three months to vegetate, and some sorts lie a whole year at least before they begin to grow, such as the hawthorn, holly, and most other of the very hard bony seeded kinds; all of which, both in the herbaceous and woody tribe, is generally hinted in the culture of the respective sorts under their proper genera. See also GERMINATIO.

For particulars in regard to the various methods of sowing of Seeds, see SOWING OF SEEDS.

SEMPERVIVUM, Live-ever, or House-leek.

The plants are of the succulent tribe, herbaceous and shrubby, consisting of low, hardy, herbaceous, ever-green perennials, for variety in the pleasure ground, &c. and medical uses, and shrubby ever-green succulents for the green-house collection, adorned with roundish and oblong, thick, fleshy, succulent leaves all the year, and the stalks terminated by bunches of polypetalous flowers.

Class and order. *Dodecandria Polygynia*.

Characters.] **CALIX**, is concave, cut into many acute segments, and permanent. — **COROLLA**, from six to ten or twelve oblong, spear-shaped, acute, concave petals — **STAMINA**, twelve awl-shaped filaments, with roundish antheræ. — **PISTILLUM**, twelve germina, placed circularly, terminating in the like number of spreading styles, crowned with acute stigmas. — **PERICARPIMUM**, about twelve oblong, compressed, circularly-placed capsules, pointed outward and opening on the inside, filled with many small roundish seeds.

There are about six or seven species, four or five of which are hardy herbaceous plants, and two are shrubby succulent exotics for the green-house.

Hardy

Hardy Herbaceous kinds.

They are low herbaceous ever-greens, with succulent leafy heads close to the crown of the root, sending up flower-stalks annually, in some a foot high, others not half so much; one sort (*Common House-leek*) grows naturally in England, &c. on buildings, or barren hills, the others in mountainous parts on the continent of Europe, but are all hardy enough to grow here, any where either in the full ground or in pots, or on tops of walls, buildings, or rock-work, &c.

¹*SEMPERVIVUM Tectorum.*

House Sempervivum, or Common House-leek.] Hath a fibrous perennial root, crowned with many ovalish, pointed, ciliated, succulent leaves, in roundish heads, close to the earth, having many spreading off-sets; and upright, round, succulent, reddish stalks a foot high, terminated by reflexed spikes of spreading red flowers, in July and August.

This is the Common House-leek, which grows naturally on the tops of buildings and barren hills in England, and most countries in Europe; and we may see it growing in tufts on the tops of sheds, and other low buildings, almost every where, with hardly any soil in which to root, for the off-sets being planted at first in a little lump of any soil, and placed on the tiles or thatch of any building or on the coping of a wall, they will readily strike and multiply into large bunches without any culture.

This species, being of a very cooling quality, is used against the St. Anthony's fire, shingles, burns, scalds, and inflammations, &c.

²*SEMPERVIVUM Globiferum.*

Globiferous Siberian House-leek.] Hath a fibrous root, crowned with numerous, narrow, ciliated, succulent leaves in compact globular heads, producing many globular off-sets; and erect, round, succulent stalks, six or eight inches high, terminated by yellowish flowers.

Variety.] With Red flowers.

This species produce numerous small globular off-sets, which being thrust off by the larger heads, and falling on the ground, &c. take root freely of themselves, and become proper plants.

³*SEMPERVIVUM Arachnoideum.*

Arachneide Alpine House-leek, or Cob-web Sedum.] Hath fibrous roots, crowned with short, narrow, succulent leaves in small

heads, having many hair-like threads, intersecting one another from leaf to leaf, resembling a spider's web; and erect, round, succulent stalks, six inches high, terminated by spikes of bright red flowers ranged mostly along one side.

⁴*SEMPERVIVUM Montanum.*

Mountain Helvetian House-leek.] Hath fibrous roots, crowned with oblongish, pointed, ciliated, succulent, smooth leaves, in expanded open heads, producing very spreading off-sets; and erect succulent stalks, eight or ten inches high, terminated by spikes of deep-red flowers.

All these herbaceous *Sempervivums* are very hardy ever-green perennials, formed of roundish clusters of succulent leaves close to the ground, &c. remaining green all the year, and from the center of the heads of leaves arise the flower-stalks annually, flowering mostly in July and August, succeeded by ripe seeds in autumn.

They are all hardy enough to grow any where in any dry soil or rubbishy banks, or in pots, and the tops of buildings, rock-work, &c.

The smallest off-set, being planted at first in a small portion of any soil, will grow and increase surprisingly.

Tender shrubby kinds.

These consist of two shrubby succulent exotics, with strong erect stems, terminated by heads of numerous succulent leaves, and spikes of flowers, and being natives of hot countries require shelter of a green-house here in winter.

⁵*SEMPERVIVUM Arboreum.*

Tree House-leek.] Rises with an upright, thick, fleshy, tree-like, smooth, branching stem, six or eight feet high, with the branches terminated by large clustering heads of spear-shaped, bright-green leaves; and, from the center of the heads, large pyramidal spikes of bright yellow flowers, in autumn and winter.

Varieties.] Variegated-leaved Tree House-leek, which is a very curious variety of a fine ornamental appearance — White-flowered. Both the varieties flower very ornamentally, and the flowers continue long in beauty.

It is a native of Portugal, Crete, and the Cape of Good Hope.

⁶*SEMPERVIVUM Canariense.*

Canary Shrubby House-leek.] Rises with an upright, succulent, rugged stalk, half a yard or more high, appearing ragged with the rudiments

diments of past foliage, having the top crowned by large globular heads of retuse succulent leaves; and from the center of the head a long pyramidal spike of greenish flowers, in June and July.

All the above six species of *Sempervivum* retain their leaves the year round, which, in all the sorts, are thick, fleshy, and succulent, and generally collected many together into round heads; and from the center of the heads arise the peduncle or flower-stalk, terminated by the flowers in summer and autumn, each flower composed of from about eight or ten to twelve petals, spreading out every way in a star-like manner, exhibiting a good ornamental appearance, and are succeeded by ripe seeds in autumn.

All the sorts being of a very succulent nature, are the most prosperous and durable in the driest light soils; and the hardy sorts, in particular, thrive on the tops of walls, buildings, and rock-work.

The four hardy sorts succeed any where, in the open air, all the year, and may be planted for variety in any dry rubbishy bank, or in pots of the like soil; also upon rock-work, the tops of walls, and buildings; for as they increase exceedingly by off-sets on every side, and these being slipped off at almost any time, and planted in a little stiff mud or strong earth, placed on any building, &c. they will grow freely, and soon multiply into large bunches, as may be observed of the Common House-leek.

The two tender shrubby sorts, requiring shelter in winter, must be kept in pots of light sandy earth, or any dry rubbishy soil, and placed among the green-house plants, where they will exhibit a conspicuous variety at all times of the year; but more eminently the *Sempervivum Arboreum* and variety, managing them as other succulents of the green-house collection, being particularly careful to water them but sparingly in the winter, as too much moisture is destructive of tender succulents in that season. See GREEN-HOUSE PLANTS.

Method of Propagation, &c.

All the four hardy *Sempervivums* are very expeditiously propagated by their off-set heads, which may be readily slipped off with roots; or even without any they will succeed; planting them in any light dry soil, or rubbish, as before observed; and if on buildings or rock-work, &c. lay a little mud

or stiff soil thereon in patches, in which plant the slips, and they will grow and flourish without farther trouble.

The two green-house kinds are propagated by cuttings of the branches and by seed.

By Cuttings.—The first of these two sorts in particular is easily propagated by cuttings of the smaller branches, any time from April or May till July, either with or without the aid of hot-beds, though, if planted early, they may be greatly forwarded by the assistance of artificial heat; however, in any of the summer months they will readily take root in a bed, or pots of natural earth, in the open air; observing, in taking off the cuttings, if they appear very succulent in the cut part, it is eligible to lay them in the dry a few days to skin over, previous to planting; then either plant them in pots of dry light soil, or in a bed of common light earth till rooted; in either method allow them occasional shade from the sun, and sometimes moderately watered in very dry weather, especially those in pots; they will thus be well rooted in two or three months, and may then be potted separately in middling pots, and placed among the other green-house exotics.

By Seed.—The Canary House-leek, in particular, producing seed in tolerable plenty in our gardens, it may be also propagated by sowing the seed in autumn, or early in spring, in pots of light earth, placing them in a frame to have shelter from frost, but exposed in mild weather; and as the warm season advances the plants will begin to appear, which, when an inch or two high, prick them in separate small pots, and manage them afterwards as other succulents of the green-house.

SERRATULA, Saw-wort.

It consists principally of tall, hardy, herbaceous, flowery perennials, for ornamenting the pleasure garden; rising with annual stalks from two to seven or eight feet high, adorned with pinnatifid and entire leaves in the different species, and the stalks terminated by scaly heads of compound flowers.

Class and order. *Syngenesia Polygamia Æqualis*.

Characters.] CALIX, an oblong, imbricated, general cup, composed of many spear-shaped, acute, smooth scales.—COROLLA, a uniform compound flower, composed of many hermaphrodite funnel-shaped florets, with an inflexed tube and ventricose limb,

CUC.

into five parts.—**STAMINA**, five short hair-like filaments, with cylindric antheræ.—**PISTILLUM**, an oval germen, filiforme style, and two oblong reflexed stigmas.—**PERICARPIUM**, none, each floret succeeded by one oval seed crowned with down.

The principal species, in the English gardens, are the following, the first of which is a native of England, the others of different parts of America, but are all of hardy growth, consisting both of fibrous and tuberous-rooted perennials,

¹**SERRATULA Tinctoria.**

Tincturaceous Common Saw-wort.] Hath a fibrous perennial root, upright annual stems, two feet high, lyre-shaped pinnatifid leaves, having the terminal lobe the largest, and the stalks terminated by scaly heads of purple and white flowers in the different varieties.

This grows naturally in woods and meadows in England, &c. and is sometimes cultivated for variety.

²**SERRATULA Noveboracensis.**

New-York Saw-wort.] Hath a fibrated perennial root, upright channelled stalks, seven or eight feet high, oblong, lanceolate, serrated, pendulous leaves, downy underneath, and the stalks terminated by heads of purple flowers.

³**SERRATULA Glauca.**

Glaucous Maryland Saw-wort.] Hath a fibrous perennial root, upright, channelled, purple stalks, six or seven feet high, oblong-oval, acuminate, sawed, glaucous-coloured leaves, and the stalks terminated by corymbus bunches of purple flowers, having roundish cups.

⁴**SERRATULA Scariosa.**

Scariosa-flowered Virginia Saw-wort, or Tuberous Knap-weed.] Hath a tuberous perennial root; upright, strong, channelled stalks, three or four feet high; spear-shaped entire leaves; and the stalks adorned upward with many purple flowers, rising laterally on obtuse peduncles, having also rough scaly calices.

⁵**SERRATULA Squarrosa.**

Squarrose Virginia Saw-wort, or Tuberous Melancholy Thistle.] Hath a tuberous perennial root, an upright stalk, near a yard high, linear, or very narrow stiff leaves, and the stalk adorned upward with purple flowers, rising laterally and sitting almost close in squarrose, or rough, scaly, acuminate cups.

⁶**SERRATULA Spicata.**

Spiked Virginia Saw-wort.] Hath a tuberous perennial root, upright single stalks, two or three feet high; linear leaves, ciliated at the base; and the stalks terminated by long spikes of close-fitting purple flowers, rising laterally.

⁷**SERRATULA Præalta.**

Præaltous Peach-leaved Virginia Saw-wort.] Hath a fibrous root, upright branching stalks, four or five feet high, oblong, spear-shaped, serrated, spreading leaves, hairy underneath, and the branches terminated by loose bunches of purple flowers.

All these species of *Serratula* are perennial in root but annual in stalk, which, rising in spring, flower in June, July, and August, in the different sorts; the flowers are universally compound, consisting of many tubular florets in large scaly calices, and in most of the sorts are tolerably conspicuous and ornamental; but those of the American kinds are not always succeeded by good seeds in our gardens; they, however, multiply fast enough by the root.

These plants being mostly of erect tall growth, are proper ornaments for the compartments of large gardens, and to interperse in shrubberies, and along the verges of woods, walks, &c.

Method of Propagation.

They are propagated by parting the roots, and by seeds.

By Parting the Roots.—All the sorts send out off-sets from the root, but the fibrous-rooted kinds the most abundantly, and the roots may be slipped or divided, either in autumn, when the stalks decay, or in spring before new ones begin to shoot up, though if done early in autumn they will flower much stronger the following year.

By Seed.—All the sorts may also be raised from seeds; but the tuberous sorts, in particular, not encreasing very plentifully by roots, they must be often raised from seeds, sowed in autumn or early in spring, in an east border, in shallow drills; and when the seedlings are two or three inches high, prick some of the thickest out in nursery-rows till autumn, then plant the whole finally to remain.

SEXUS Plantarum, Sexes of Plants.

The different Sexes of plants, with regard to their being male, female, or hermaphrodite, is determinable by their flowers and fruit only.

All plants, from the largest tree down to the smallest mosses and fungi, and other the most minute vegetables, are furnished with flowers either visible or invisible, or concealed; but in the greater number visible and conspicuous: and in either case the flowers are the genitals or generative organs of all vegetables, being furnished with male, female, and hermaphrodite fructifications, sometimes on different plants of the same genus, and sometimes both male and female on different parts of the same plant; but the greater part of the vegetable kingdom is of the hermaphrodite kind, having both male and female organs (*stamina* and *pistillum*) all within the same flower: all which genital parts, or fructifications in the above different sexes, being essentially necessary for the purpose of generation, as serving the important office of fecundation to impregnate the embryo fruit, and fertilize the seed. See GENUS, and FLOS; also FOEMINA FLOS, MASCULUS FLOS, HERMAPHRODITUS FLOS, FRUCTIFICATIO, &c.

Every flower, however large or minute, is furnished with genitals, *i. e.* *stamina* and *pistillum*, either in the same or in different plants and flowers, &c.

For example:

Male plants are such as produce male-flowers only, which male-flowers are those that are furnished only with the *stamina*, consisting of the filaments and antheræ, being the male genitals, but want the *pistillum*, or female organs.

Female plants being productive of female flowers only, such as are furnished with the *pistillum*, consisting of the germen, style, and stigma, the female fructifications, but want the *stamina*, or male genitals.

And hermaphrodite plants are those which produce only hermaphrodite flowers, being such as contain both *stamina* and *pistillum*, the male and female organs, all within the same calix and corolla, as prevail in the greater number of the vegetable creation.

Likewise observe,

Monoecious, or androgynous plants, are such as produce both male and female flowers distinct, situated on different parts of the same vegetable, as in the cucumber, melon, and many other. See the Class MONOECIA.

Polygamous plants. Such that bear the several sexes of flowers, as hermaphrodite and male and female flowers together. See the Class POLYGAMIA.

The existence of the Sexes of plants was greatly disputed by many of the ancient botanists and others; but whoever is still doubtful in that point, will but examine the curious structure of flowers, and make some experiments, will soon be convinced, that the flowers of all plants are furnished with proper generative organs; and that the male genitals, the filaments, and antheræ, being furnished with a certain subtle powder impregnates therewith the *pistillum* of the females, and fertilizes the embryo fruit and seed in the germen, or ovary; so that when the flower fades, the fruit swells, and the seeds become fertile, as may be experienced in early cucumbers in frames by carrying the antheræ of the male blossom and touch the stigma of the female flower therewith, so as to leave some of its golden powder on the stigma, or female organ, which infallibly impregnates the germen, or miniature fruit, and it will soon visibly swell and increase fast in magnitude, furnished also with fertile seed, which, without being previously fecundated by the male dust, generally prove sterile, or barren, and if sowed they would not germinate.

So that if we were to remove all the male flowers of cucumbers, or melons, erroneously called false-blossoms, before they blow, we render the females, or fruit-blossoms, abortive.

Likewise, if flowers of any sort were castrated, or deprived of the male organs, the filaments and antheræ, before they ripen their impregnating powder of the antheræ, the female parts would become sterile, or, at least, the fruit would either not swell at all, or but very imperfectly, and the seeds would remain unfertilized, and if sowed they would not grow.

For although some sorts of plants may probably by chance produce a sort of imperfect fruit and seeds, without the immediate vicinity of male flowers, the same as a hen may lay eggs without the congress of a cock, yet for want of being fertilized with the male sperm, neither will the seeds grow, nor the eggs bring forth chickens.

Linnæus, in his definitions of the Sexes of plants, says, the calix is the marriage-bed in which the male and female organs consummate the nuptials of plants, and in which these tender organs are cherished and defended from external injuries; and the corolla, or petals, are the curtains closely surrounding

ing the genitals, in order to resist storm, rain, or cold; but when the sun shines bright they expand freely, both to give access to the fecundating dust and to the sun's rays, to promote the fecundating faculty of the said powder, in acting with due effect on the stigma and style: for the filaments are the spermatic vessels of the males, by which the juice secreted from the plant is carried up to the antheræ in form of a fine powder, which is the pollen, or male dust, answering to the male sperm of animals, or the roe of fishes; for although it is dry, it is more easily conveyed by the winds, or air, to the stigma, or female organ, where it is moistened, thence proceeds to the style, which is the vagina, or tube through which the effluvia, or male dust passes to the germen, or ovary, and there impregnates the fruit or seed, which immediately becomes fertile, and then the petals of the flower withers, and the fruit and seed grow fast to perfection.

Thus we need not wonder, that in the vegetable kingdom such numbers of plants are of the hermaphrodite race, *i. e.* the flowers having both male and female organs within the same calix and corolla; though in the animal kingdom there are very few of the hermaphrodite kind, for here one sex can easily go to another, whereas plants are fixed to one spot and cannot go from it, so that the male and female parts of fructification being within the same cover, the fecundation is more easily effected by nature.

Other plants again having the male and female parts in different flowers, have their situation on the plants and their genitals so wonderfully disposed by nature that the fecundation is effected by the winds and certain insects conveying the male dust from the antheræ to the female organs.

Most plants appear the most beautiful when in flower; but when the genitals of the flower have performed their natural function, the flower soon after fades, and many plants gradually lose much of their former splendor, and numerous sorts, after flowering and ripening seeds, either decay wholly, as in all the annual and biennial tribe, and some only die down to the root, as in numerous herbaceous perennials; likewise some plants and trees, after obtaining a great age and bulk, totally decay, after having once flowered; such as often occurs in the *agave*, or great American aloe, which in this country

in particular, after fifty or an hundred years growth before they attain a flowering state, they then expanding in the centre and shoot up rapidly, into a stalk of prodigious height, for flowering, which continuing in bloom two or three months, and the plants generally decay soon after, never surviving to flower again: the same also happens in the *musa paradisiaca*, or plantain-tree, which having been in some European gardens a hundred years, and after having once flowered, no art can prevent its lofty stem from perishing the year after; and the like also often occurs in the *lavatera arborea*, or tree-mallow.

SIDEROXYLON, Iron-Wood.

It consists of shrubby ever-green exotics of Africa, retained here in hot-houses for variety; are adorned with oval leaves, in one sort large, the other small, and monopetalous wheel-shaped flowers.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, is small monophyllous, five-parted at top, and permanent.—COROLLA, is monopetalous, wheel-shaped, and five-parted.—STAMINA, five awl-shaped filaments, having oblong incumbent antheræ.—PISTILLUM, a roundish germen, awl-shaped style, and simple obtuse stigma.—PERICARPIUM, a roundish umbilicated unilocular berry, containing one oval unilocular nut.

There are about three species, one of which is inermous, or without spines, the others are spinous.

¹SIDEROXYLON *Inerme*.

Inermous, or Smooth Æthiopian Sideroxylon.] Rises with a shrubby stem, branching irregularly six or eight feet high, being inermous, or without spines, garnished with large, oval, firm, smooth, shining, green leaves, and flowers at the sides and ends of the branches.

²SIDEROXYLON *Spinosum*.

Spinous Malabar Sideroxylon.] Rises with a shrubby branching stem, several feet high, armed with spines, small, oval, firm, smooth, perennial leaves, and flowers at the ends of the branches.

The above two plants rarely flower in England.

They being tender exotics from hot countries, must be kept always in pots and placed in the stove.

³SIDEROXYLON *Lycioides*.

Lycioides, or Canada deciduous Sideroxylon.] Hath a shrubby stem and branches, armed with

with spines, and garnished with spear-shaped, shining green, deciduous leaves.

The wood of these shrubs being so very solid, remarkably hard and ponderous, as to sink in water, they obtained the appellation of Iron-wood.

They are propagated by seeds procured from abroad, which, of the two first sorts in particular, must be sowed in spring, in pots of rich earth, and plunged in the bark-bed; and when the seedlings are come up two or three inches high, pot them off separately, and place them always in the stove.

Their propagation may also be tried by layers and cuttings, assisted by heat.

SILENE, Viscous Champion, &c.

The plants are mostly hardy herbaceous annuals and perennials, some of which merit culture, as flowering plants, which are principally of erect growth, with stalks about half a yard, or two or three feet high, garnished with oblong, oval, and narrow simple leaves, and the stalks terminated by bunches of small pentapetalous flowers.

Class and order, *Decandria Trigynia*.

Characters.] CALIX, is monophyllous, quinque-dentate, and permanent.—COROLLA, five plane, obtuse, sometimes bifid petals, with narrow unguis, and a nectarium formed of two denticles in the neck of each petal.—STAMINA, ten awl-shaped filaments, alternately inserted into the unguis of the petals, having oblong antheræ.—PISTILLUM, a cylindric germen, three simple styles, crowned by stigmas, reflexed contrary to the sun.—PERICARPIUM, a cylindric trilocular capsule opening five ways at top, and many reniforme seeds.

There are many species, annuals, biennials, and perennials, and of which the following are the most noted sorts.

¹SILENE *Armeria*. (Annual.)

Armeria, commonly called *Lobel's Catch-fly*.] Rises with erect, branchy, clammy stalks, half a yard high, having the upper leaves heart shaped, and all the branches terminated by fastigiated bunches of flowers, of different colours in the varieties.

Varieties.] Common red-flowered, — white flowered, — purple-flowered. — All of which flower in June and July.

²SILENE *Quinquévulnæra*. (Annual.)

Quinquévulnæra, *Viscous Champion*, commonly called *Dwarf Lychnis*.] Rises with upright channelled stalks, branching numerously twelve or fifteen inches high, oval

spear-shaped, hairy, opposite leaves, and all the branches terminated by short spikes of purple flowers edged with white, having roundish entire petals, succeeded by erect fruit alternately: appearing in May, June, and July.

Both the above species are hardy annual flowers, and have been in estimation for adorning the borders in summer, being commonly sowed in small patches in the places where they are to flower.

³SILENE *Muscipula*. (Biennial.)

Muscipula, or *Spanish Viscous Champion*.] Hath a biennial root, an upright, round stalk with swelling joints, and branching by pairs, a foot and half high; narrow spear-shaped, smooth leaves, surrounding the stalk in clusters; and at the axillas, close-fitting, red-flowers, with bifid petals.

⁴SILENE *Viridiflora*. (Biennial.)

Green-flowered Portugal Champion.] Hath a biennial root, upright, taper, downy stalk, branching alternately a foot or more high; oval, spear-shaped, downy leaves, and the branches terminated by panicles of whitish-green flowers.

⁵SILENE *Nutans*. (Perennial.)

Nutant or Nodding Mountain Champion.] Hath a fibrous perennial root, upright stalks, two feet high, spear-shaped leaves; and from the upper part of the stalks, nodding panicles of white flowers arranged, drooping on one side, having bifid petals.

⁶SILENE *Bupleuroides*. (Perennial.)

Bupleuroides-leaved Persian Champion.] Hath a perennial root crowned with large clustered heads of spear-shaped acute leaves, upright stalks a foot and a half high; and opposite pedunculi, each sustaining two or three white flowers with bifid petals and short bractea.

⁷SILENE *Fruticosa*. (Perennial.)

Shrubby Sicilian Viscous Champion.] Rises with a low shrubby stem, branching a foot or more high, having broad spear-shaped leaves, trichotomous panicles of greenish white flowers.

All these plants flower here in summer from May till August in the different sorts, each flower having five petals, and several of the sorts produce ripe seeds, particularly the annuals and biennials, by which all the sorts may be raised, and the perennials also by parting the roots, &c.

They are all hardy herbaceous plants, and for the general part have very viscous or clammy

clammy stalks, particularly just below the joints, to which flies often stick fast, hence the name Catchfly, and Viscous Cam-pion, &c.

They will all prosper in any of the garden compartments, and may be employed for ornament and variety in different parts of the pleasure-garden.

The two annual sorts, in particular, are cultivated in many gardens as flowery plants, which being raised from seed may be sowed in autumn or spring, where they are to flower: the autumnal-sowed plants flower earlier and strongest, though it is best to sow at both seasons, repeating also the sowing in spring and early part of summer, in order to obtain a longer bloom, observing to sow them in patches about the borders; and after the plants come up thin out the weakest, leaving only two or three in each patch, and they will then grow strong and flower plentifully in June and July, and ripen abundance of seeds in autumn.

The biennial sorts are raised from seeds sowed in autumn or spring in a bed or border and raked in, and when the plants are come up an inch or two high, prick them out in nursery-beds till autumn, then transplant them into the borders, &c.

The perennials may be propagated by slipping their heads, and parting the roots, and the shrubby sort also by slips of its branches in a shady border.

They may also be raised from seeds like the biennial.

SILPHIUM, Bastard Chrysanthemum.

The plants are principally tall-growing, herbaceous perennials for ornamenting the pleasure-ground, rising with annual stalks several feet high, adorned with divided and entire leaves, and the stalks crowned with compound radiated flowers.

Class and order. *Syngenesia Polygamia Necessaria*.

Characters.] CALIX, is oval, scaly, imbricated, and permanent, having the scales prominent and reflexed in the middle.—

COROLLA, a compound radiated flower, consisting of funnel-shaped, barren, hermaphrodite florets in the disc, and spear-shaped females in the radius.—STAMINA, five small filaments in the hermaphrodite florets, having cylindric antheræ.—PISTILLUM, in the hermaphrodites a taper germen, long slender hairy style, and simple stigma; and in the females a heart-shaped germen, short

simple style, and two bristly stigmas.—PERICARPIUM, none.—SEMEN, no seed in the hermaphrodite, but in the females single heart-shaped seed, having a membranaceous two-horned border.

The species are,

¹SILPHIUM *Trifoliatum*.

Trifoliate Virginian Silphium.] Hath a fibrated, ligneous, perennial root, upright, firm, purplish stalks, branching four or five feet high; large, oblong, rough, sharply-ferrated leaves, generally by threes or fours round the stalk; and at the sides and ends of the branches long peduncles, each sustaining one radiated yellow flower.

²SILPHIUM *Solidaginoides*.

Solidaginoide Virginian Silphium.] Hath a fibrated perennial root, upright stalks a yard high; spear-shaped, acute, ferrated, opposite leaves on short foot-stalks; and the stalks terminated by radiated yellow flowers loosely disposed.

³SILPHIUM *Asteriscus*.

Asteriscus, American Sylphium.] Hath a fibrous, perennial root, upright, thick, hispid stalks three or four feet high; oblong, rough, undivided, close-fitting leaves, alternate below, but opposite above; and the stalks terminated by radiated yellow flowers.

⁴SILPHIUM *Laciniatum*.

Lacinated American Sylphium.] Hath a fibrous perennial root; upright, very thick, taper, simple stems, eight or nine feet high; large pinnatifid, sinuated leaves alternately; and the stalks terminated by radiated yellow flowers.

All these four species flower here annually in July and August, the flowers are universally compound and radiated, each flower consisting of many florets in one scaly, imbricated, general calix, tubular florets in the disc, and spear-shaped ones from the radius; but the seeds do not ripen freely in England.

They are all very hardy herbaceous perennials, durable in root, but renew their stalks annually in spring, which flowering in summer, decay to the root in autumn.

All the sorts are proper ornamental furniture for large compartments in assemblage with other tall-growing perennials, where they will effect a good variety in summer.

They are all easily propagated by parting their roots in autumn, planting the slips at once where they are to remain, and they will flower the following year.

SINAPIS,

SINAPIS, Mustard.

The plants are mostly hardy herbaceous annuals, some of which merit culture as esculent herbs, both for fallading and for their seeds for making mustard; all of which rise with erect branchy stalks from two to three or four feet high, garnished with broad, rough, deeply-jagged leaves, and the branches terminated by spiked clusters of tetrapetalous cruciforme flowers.

Class and order. *Tetradynamia, Siliquosa.*

Characters.] CALIX, four narrow, cruciforme, deciduous leaves.—COROLLA, four roundish, plane cruciforme petals, and four oval nectari.—STAMINA, four long and two short filaments, having erect patent antheræ. PISTILLUM, a taper germen, a style the length thereof, crowned with a headed stigma.—PERICARPIUM, an oblong, swelling, rough, bilocular, bivalvous pod, having many globose seeds.

The principal species for general culture are,

¹SINAPIS *Alba.*

Common White Mustard.] Rises with large, rough, jagged leaves, upright, branchy, hairy-stalks two feet high, or more, garnished also with jagged rough leaves, and all the branches terminated by loose spikes of numerous yellow flowers, succeeded by hispid pods, having long oblique beaks, and contain white seeds.

This is the common White Mustard usually cultivated in gardens as one of the small fallad-herbs, and may also be raised for its seed to make Mustard.

²SINAPIS *Nigra.*

Black Mustard.] Rises with erect, branching stalks, four feet high or more, garnished with large, rough, jagged leaves, and the branches terminated by spiked clusters of yellow flowers, succeeded by smooth pods, tetragonous at top, containing blackish-red seeds.

This is the sort which is commonly cultivated in fields for its seed, of which to make the common Mustard for general use.

³SINAPIS *Arvensis.*

Field Sinapis, or Durbam Mustard.] Rises with erect stalks two feet high, garnished with oblong, rough leaves, and the branches terminated by bunches of yellow flowers, succeeded by multangular, swelling, turgid pods, with long beaks.

The two first species flower in June and the seeds ripen in July and August, but the

third flowers in May and the seeds ripen in June.

These three species of *Sinapis* are hardy herbaceous annuals, that grow naturally in the fields in England, and most parts of Europe; but the second and third sort, in particular, grows abundantly among the corn, and by way-sides in many parts of England, and are also cultivated in gardens and fields in large quantities for their seeds for Mustard; the *Sinapis Alba*, however, is cultivated in gardens principally as a fallad-herb: and the *Sinapis Nigra*, and the Field *Sinapis* are the chief sorts that are cultivated for their seed to manufacture for Mustard; but of the seed of the third species in particular is made that sort called Durham Mustard; however, good Mustard may be made of all the three sorts, all of which being sowed in the spring soon come up, shoot up to stalks, and produce ripe seeds in three or four months, then totally perish; so that a fresh supply is raised annually from seed.

The White Mustard, however, being used in gardens as a fallad-herb, is sowed along with other small fallading at all times of the year, even sometimes every week or oftener, in a bed or border of light earth, sowed generally in shallow drills very thick, covering it very thinly with earth; and in winter, and early in spring, during the cold weather, is sowed also in hot-beds; and the herbs are always cut for use whilst in the seed-leaf and but a few days old; otherwise they will become too strong and rank tasted.

But for the particular methods of raising this sort as a fallad-herb, together with other small fallading at different times of the year. See SALLAD-HERBS and SMALL SALLADING.

Observe, in order to save seed of this sort for garden use, sow it on an open spot of ground in March or April, either thinly in drills a foot asunder, or broad-cast all over the surface, and let the plants run up to stalk, and they will furnish ripe seeds in August.

To raise the plants for the seed for Mustard, they should be sowed in the spring, any time in March, in some open situation either in a kitchen-garden, or in the open fields, where large quantities are required for sale; in either case, having digged or ploughed the ground, then sow the seed broad-cast all over the surface, and rake or harrow them in lightly, or sow it in shallow drills a foot asunder. They will soon come up, observing, that when the plants have four or more leaves

leaves an inch or two broad, those sowed in the broad-cast way should be hoed and thinned, leaving them ten or twelve inches asunder, and cut up all weeds, repeating it once or more if necessary; after this the plants will soon spread and cover the ground, and shoot fast up to stalks for flowers and seed, which will ripen in July or August, and the third probably in June, when the stalks should be cut or pulled up, and thrashed out for use.

SISIMBRIUM, Water-Cress.

Consists of hardy herbaceous annuals and perennials, mostly of the aquatic tribe, one of which is in high estimation as a sallad-herb; are mostly of spreading growth, garnished with pinnated and pinnatifid leaves, and the stalks terminated by spikes of small tetrapetalous cruciforme flowers.

Class and order, *Tetradynamia Siliquosa*.

Characters.] CALIX, four linear, spear-shaped, spreading, deciduous leaves.—COROLLA, four oblong, patent, cruciforme petals.—STAMINA, four long and two short filaments, having simple antheræ.—PISTILLUM, an oblong, slender germen, very short style, and obtuse stigma.—PERICARPIUM, a long, taper, incurved, bivalvous bilocular pod, having many small seeds.

There are more than twenty different species of this genus, but the greater part being plants of no merit are rarely cultivated: one sort however, *Common Water-Cress*, demands attention as a wholesome sallad-herb.

SISYMBRIUM *Nasturtium*.

Nasturtium Aquaticum, or Water-Cress.] Hath a fibrous, spreading, perennial root, striking deep in the mud under the water, and sends up several branchy shoots, becoming hollow stalks, garnished with pinnated leaves of four or five pair of nearly heart-shaped lobes, and an odd one, and the branches terminated by loose spikes of small whitish flowers, in June, and the seeds ripen in July.

This plant is a perennial, grows abundantly in shallow standing waters, on the margins of small rivers, brooks, running springs, watery ditches, and moist meadows, almost every where; and being of a fine warm, agreeable, fat relish, is greatly esteemed as a winter and spring sallad herb, and as such every one may obtain it at an easy rate, either by gathering it themselves where it grows naturally, or by purchasing it of the simplers, or herb people, especially about London, where great quantities are

daily brought for sale in autumn, winter, and spring, tied in small bunches, which they retail for a penny or two-pence *per dozen*; and many people buy them constantly as a choice, wholesome, palatable sallad, to eat either alone, or mixed with other sallad-herbs.

It is a good purifier of the blood, and is admirable against the scurvy.

This plant, however, as it grows wild in great plenty almost every where in watery places; is rarely cultivated in gardens, though it may be easily raised abundantly in any ditches of water, shallow ponds, and other moist places, either by transplanting the plants with roots from the places of their growth, or by seed.

Its propagation therefore may be effected both by parting the roots and by seed.

By parting the Roots.—In spring, or any time of the year, whilst the plants are young, may easily slip off a quantity, with plenty of roots to each, which plant directly, in some shallow, watery place, as before observed, they will readily strike into the mud, spread considerably, and will ripen seed and sow themselves, and furnish plenty of plants for use.

By Seed.—Procure a quantity of the seed in summer as soon as ripe, in the places where the plants grow naturally, and sow them directly in any moist place to remain; or get a quantity of the plants just as the seeds begin to ripen, and throw them into any shallow water, they will strike root, ripen, and shed their seeds, which falling to the bottom will grow and furnish plenty of young plants.

SISYRINCHIUM *Bermudiana*.

The plants are low, herbaceous, flowery perennials for the pleasure-garden, rising with sword-shaped leaves and stalks half a foot high, adorned at top with spathaceous hexapetalous flowers.

Class and order, *Gynandria Triandria*.

Characters.] CALIX, is a spatha, or sheath, formed of two compressed, keel-shaped leaves.—COROLLA, six oblong-oval, acute-pointed, spreading petals.—STAMINA, three very short filaments, with bifid antheræ affixed to the style.—PISTILLUM, an oval germen under the flower, awl-shaped style, and trifid reflexed stigma.—PERICARPIUM, an oval trigonous, trivalved, trilocular capsule, having numerous roundish seed.

There is but one species, which, however, comprehends two or three varieties, all of which are fibrous-rooted perennials.

The

The species is,

SISYRINCHIUM Bermudiana.

Bermudian Sisyrinchium.] Hath a fibrous perennial root, crowned with several sword-shaped, two-edged, stiff leaves, five or six inches long; amidst them an erect, two-edged stalk half a foot high, garnished also with sword-shaped, amplexicaule leaves, and adorned at top with several spreading deep-blue flowers, having yellow bottoms.

Variety. Virginian Sisyrinchium.] Hath a fibrous perennial root, crowned with narrow, sword-shaped leaves, but three or four inches long, and erect two-edged stalks the same height, terminated by two or three pale-blue flowers.

Both these varieties flower in June, and are succeeded by ripe seeds in autumn.

They may be employed as flowery plants in any of the compartments of the pleasure-ground, placing them towards the front in assemblage with other low perennials, where they will cause an agreeable variety.

Their propagation is by parting the roots, and by seed.

By parting the Roots.—This may be performed in autumn, any time in September or October, when the roots may be taken entirely up, and slipped into several separate offsets, but not too small, planting them again directly, and they will root firmly before winter, and flower the year following.

By Seed.—Sow them in autumn, or early in spring in an east border, in shallow drills, covering them half an inch deep; they will come up in April or May like grass, keep them weeded all summer, and towards autumn prick out a quantity in nursery rows six inches asunder, to stand till spring, then transplanted with balls, to where they are to remain.

SIUM Water-Parsneps and Skirret.

This genus is composed of hardy herbaceous perennials, one of which, (Skirret.) having an esculent root, is sometimes cultivated in kitchen-gardens, the others being plants of no merit are rarely cultivated; they rise mostly with winged leaves and upright annual stalks, terminated by umbellate clusters of flowers.

Class and Order, Pentandria Digynia.

Characters. CALIX, umbellate flowers, having the general umbel composed of several smaller plane umbels, with the general involucre formed of many spear-shaped, reflexed leaves, and the partial ones of many

small narrow leaves.—COROLLA, the general umbel is uniform and composed of many small flowers, each having five heart-shaped, inflexed petals.—STAMINA, five filaments with simple antheræ.—PISTILLUM, a small germen under the flower, two reflexed styles, and obtuse stigmas.—PERICARPIUM, none.—SEMEN, two oval seeds to each floret.

There are seven or eight species of this genus, one of which only, an esculent, have merit as garden-plants, some being wild weeds of ditches, and other moist places in England, &c. and seldom admitted into gardens.

The garden-foet is,

SIUM Sifarum.

Sifarum, or Skirret.] Hath a perennial eatable root, composed of several oblong, thick, fleshy fibres, collected into a head at top, crowned with pinnated leaves, of two or three pair of oblong folioles and an odd one, and when it shoots to seed, rises with an upright stalk a foot high, having ternate leaves above, and terminated by an umbel of white flowers.

The root of this plant is eatable, of a sweetish relish, being boiled and eaten like carrots and parsneps, and was formerly in much esteem, but has become in disrepute of late years; it is, however, accounted a very wholesome root.

Method of Propagation.

It is propagated both by seed and by offsets of the roots.

By Seed.—In spring, any time in March, or beginning of April, is the season for sowing, chusing an open situation, which being properly digged, sow the seed either broadcast all over the surface and raked-in, or in shallow drills a foot asunder; they will come up in a month or five weeks, and in two or three weeks after, they must be cleaned from weeds and thinned either by hand or hoe, leaving the plants six or eight inches distance; the plants will soon after cover the ground with their leaves, and the roots encrease in growth till the leaves decay in autumn, then they will be fit for use, and continue good till next spring, when they will shoot up for seed.

By Off-sets of the Root.—The roots put out many side off-sets, which in spring being slipped off separately each with one or more buds or eyes at top; and in an open spot of ground plant them with a dibble in rows a foot

foot asunder, with the crown of each slip an inch within the ground; or may plant them thin by trench planting, in small trenches, as for asparagus, placing them erect against the back of the trench, and cover in the mould over them the above depth; in either method the plants will soon come up strong, and by autumn following the roots will be full-grown, and encreased into large bunches fit to take up for use from October till March.

To save seeds of this plant, let a few of the large roots stand to shoot up into stalks, which will flower in July, and the seeds will ripen in autumn.

SLIPS, the propagating plants by Slips.

Great numbers of plants, both woody and herbaceous kinds, are propagated plentifully by Slips; and the method is very easy as well as very expeditiously performed.

It is effected in the woody kinds by slipping off young shoots from the sides of the branches, &c. with the thumb and finger, instead of cutting them off with a knife, and are therefore called Slips, which in numerous small, shrubby plants will grow; but is more commonly practised to the lower ligneous plants, such as sage, southernwood, rosemary, rue, lavender, and most other low shrubby growths, which may with the utmost facility be multiplied by this method: and the best season of the year for effecting the work is generally in spring and beginning of summer, though many sorts will grow if planted at almost any time of the year; but the proper season for the various plants is always hinted in their culture, under their respective genera.

Observe, in performing the work of slipping these sorts, to chuse the young shoots chiefly of but one year's growth, and in many sorts the shoots of the year will grow the most readily even to plant the same summer they are produced, especially the hard wooded kinds, but in the more soft-wooded plants, the Slips will also often readily grow when a year or two old; being careful always to chuse the most robust shoots situated on the outward part of the plants, from three to six or eight, or ten inches long, slipping them off close to the branches; and clear off the lower leaves, then plant them two parts of three in the ground, giving occasional shade and water, if in summer, till properly rooted; and then towards au-

turn transplant them where they are to remain.

Many shrubby plants growing into large bunches from the root, such as roses, spiræas, raspberries, and numerous other sorts, all of which may be slipped quite to the bottom into separate plants, each furnished with roots, and may be planted either in nursery-rows, or at once where they are to remain.

As to the slipping of herbaceous plants, numerous sorts multiply by the root, &c. into large bunches, which may be slipped into many separate plants; and it is effected by slipping off the encreased suckers or off-sets of the root, and some sorts by the off-sets from the sides of the head of the plants, and some few sorts by Slips of their stalks or branches; but for the greater part by slipping the roots, as in most of the bulbous-rooted tribe, and innumerable fibrous-rooted kinds.

The slipping of the bulbous plants is performed in summer when their leaves decay, and the roots being then taken up, slip off all the small off-sets from the main bulb, and the Slips and off-sets should generally be planted again soon in nursery-beds for a year or two. See **BULBUS**.

And as to the fibrous-rooted sorts, the slipping should generally be performed in the spring, or early part of autumn, which may be effected either by slipping the outside off-sets with roots, as the plants stand in the ground; or to perform it more effectually, may take the whole bunch of plants up, and slip them into several separate parts, each Slip being furnished also with roots, planting them, if small, in nursery-rows a year, to gain strength; or such as are strong may be planted at once where they are to remain.

Farther particulars of the method of slipping plants is mentioned in the culture of the different sorts under the proper heads.

SMALL SALLAD HERBS.

Several young seedling-herbs of a warm nature are in estimation for Small Sallading to mix with the larger principal Sallad Herbs, as observed on a former occasion, such as lettuce, endive, and celery, in order to improve their flavour and wholesome quality.

The sorts therefore in general estimation as Small Sallad Herbs, are cressies, mustard, radish, rape, and turnep; also sometimes lap-cabbage-lettuce for winter and early spring

spring use; all of which herbs considered as Small Sallading, are always in perfection as such, when quite young, that is, not more than a week, or ten or twelve days old, whilst they remain mostly in the seed-leaf, being then cut up close to the ground for use; for they being mostly of a warm relish, in which consists their chief excellence for winter and spring Sallads, if suffered to grow large, and come into the rough leaf, they become of a disagreeable, strong, hot taste; but being used when only a few days old, consisting principally of the seed-leaves, as just above observed; they eat exceedingly tender with an agreeable warm flavour, highly relishing to most palates, which renders them eminent furniture to mix in all winter and spring Sallads particularly; but from June till September they are not so generally regarded, though many persons are fond of them at all seasons of the year, and in default of other Sallad Herbs many often use them alone as Sallading in the winter and spring months; they, however, are preferable when mixed with lettuce and the other principal Sallad Herbs. See SALLAD HERBS.

Let it be observed, all the above-mentioned Small Herbs belong to different genera, and that, besides their uses for Sallads, several of them are also cultivated for other useful purposes, all of which is hinted, together with their proper culture for their several uses under their respective genera; but considered as Sallad Herbs, they require a particular culture, and we therefore judged it eligible to exhibit their culture for that purpose under this head, *Small Sallad Herbs*, and, as such, the same culture serves for all the sorts, they being all raised from seeds at various sowings the year round, as directed in their culture below.

Observe, therefore, that for the purpose of Sallading they may be obtained young at all times of the year, in spring and summer in the open ground; and in winter under shelter of frames and glasses, and occasionally in hot-beds.

General Observations on their Culture.

They are all raised from seed, which for Sallading, is sowed at all times of the year, when they are required; in the open ground, from March till October or November, and in the winter months they will require shelter of frames and glasses, &c. and the assistance of hot-beds occasionally, as we before

noticed: and where a constant supply is required, a repetition of sowing will be requisite every week, or ten days, or a fortnight, according to the season of the year and the demand for use, being sowed generally in flat shallow drills, very thick, and only just covered with earth, and are also sometimes sowed all over the surface, especially upon hot-beds.

But as they require somewhat different culture at different times of the year, we will exhibit it under different heads accordingly, viz. *Spring Culture*, *Summer Culture*, *Winter Culture*.

Spring Culture.

In the spring-culture of Small Sallading, it may be raised both in the open borders and in hot-beds occasionally, according as it may be required, early or late, but when it is required as early as possible it must either be sowed in hot-beds under frames and lights, &c. or in default of a hot-bed, in a warm border under glasses.

First the early culture in Hot-beds.—You may begin to sow in hot-beds any time in January or February, and when a considerable supply is daily required, may continue sowing every week or fortnight in hot-beds till March, or during the cold weather. Let a moderate hot-bed of dung be made for one, two, or more garden-frames, only half a yard, or two feet depth of dung, according to the temperature of the season, as the heat is only required to bring up the seeds quickly, and forward the plants about a week; place a frame thereon directly, and mould the bed all over with light rich earth, five or six inches thick, making the surface level and smooth; then if you would forward your Sallading as much as possible, you may directly sow the seed, which may be effected either in drills as shallow as possible, about three inches broad, and flat at the bottom, and three inches asunder, sowing the seeds of each sort separate and very thick, so as almost to cover the ground, and only just cover them with earth: or, to make the most of the bed, may sow the seed all over the surface, previously smoothing it lightly with the back of the spade, then sow the seeds all over the bed, the different sorts separately, and all very thick, as just observed, and after pressing them all even and lightly down also with the spade, cover them very thinly with earth, by sifting over as much light mould as will only just cover the seed, as aforesaid, and as soon

soon as the sowing is performed in either method, put on the lights; the seeds will quickly germinate and will come up in two or three days or less, being careful at this time to give vent to the steam arising in the bed, as well as indulge the plants with plenty of free air daily, either by tilting the lights in back or front, according to the temperature of the weather, or by drawing the lights a little down, or taking them quite off occasionally in mild days at first; for the hot-bed being yet new, there will be a considerable steam arising, and the Sallading coming up very thick, unless due vent is given to pass off the steam and admit fresh air, they will be apt either to burn, or fog (as the gardeners term it) and mould off as fast as they come up. Such hot-beds, however, that are not fresh made, do not require all this precaution, but in new made beds it must be strictly observed till the Sallading is all fairly come up, and as long as the strong steam continues, and the plants will be fit for use in a week or ten or twelve days from the time of sowing.

Thus continue to repeat the sowing in hot-beds every week or ten days during the cold weather; the same hot-bed sometimes retaining its heat, will admit of two sowings, by sowing again as soon as the first crop is gathered; however to obtain a regular supply daily, continue to make fresh hot-beds occasionally, sowing and managing them as above.

Sometimes where only a small quantity for family use may be wanted only at a particular time, as soon as possible, and that you have the convenience either of cucumber and melon hot-beds, or a hot-house, &c. some seed of each sort may be sowed in pots or boxes, and placed in the said hot-beds or stove just to bring up the plants fit for use; which on some particular occasion may be sufficient without making a hot-bed on purpose.

For want of frames and lights to place over the hot-bed, may use hand or bell-glasses, or arch the bed with low hoop-arches, in order to cover with mats at night, and in bad weather.

Or in default of hot-beds in cold weather early in the spring, may prepare part of a warm-border, or other sunny situation, for some garden-frames and lights, hand-glasses, &c. raising the ground somewhat to the sun; and having dug it, and raked it fine, then sow the seed either in shallow drills, as before observed, or all over the surface in the

manner as directed also in the hot-bed culture, covering it lightly with earth, and having set on the frames and glasses, the seeds will soon come up, and the Sallading will be ready some considerable time sooner than in the open ground.

Their Culture in the Full-ground.—From about the middle or end of February, or beginning of March, according to the forwardness or mildness of the season, may begin sowing Small Sallading in the open ground, repeating the sowings every week or ten days; the first sowing being performed on a warm border, and continue sowing in that situation till the beginning or middle of April, then it may be sowed in any of the open quarters, and in which the sowings may be repeated weekly; but according as the hot-weather approaches should rather sow in a somewhat shady situation.

Let the ground for each sowing, in the different situations, be properly digged, and the surface raked smooth.

And as to the method of sowing in the open ground, it is most commonly in shallow drills, which should be drawn with a small or middling hoe held edge-ways downward, flat, or horizontally, drawing the drill along the width of the hoe, as shallow as possible, and flat or level at bottom, and three or four inches asunder, in which sow the seed evenly all along the bottom, each sort separate, and very thick, covering them in evenly with the finest of the mould, not more than a quarter of an inch deep; or if the smaller seeds are but just covered it is sufficient, for the seeds being sowed very thick, if deeply covered with mould the plants will not be able to rise regularly.

Observe in the early spring-sowings in the open ground, that in cold nights and all bad weather, it is eligible to cover the ground both before and after the plants begin to rise, with large mats, which will be better if supported on low hoop-arches, or ranges of pegs stuck in the ground, just high enough to support the mats a little from the earth, and by assistance of this covering, occasionally in the early sowings, you will ensure a more effectual crop, as well as forward the Sallading some days.

Remark, likewise, of the later sowings, that when the dry warm weather commences it is proper to give occasional waterings.

Observe farther, that as Small Sallading being always sowed extremely thick, and the plants

plants consequently coming up very close together, and the ground being sometimes by means of wet crusted or caked at top, so as they cannot readily make their way through, in which case it is proper to whisk the surface of the earth lightly with the hand, or with a slender broom just to break and disperse the mould a little.

Summer Sowings.

Small Sallading is not in general esteem during the hot weather in summer, from the middle or end of May until September.

However, some require it all summer long, and it may be sowed in any open situation from May till September: observing, however, that during the hot dry weather, it should either be sowed in some shady borders, or shaded with mats in sunny days during the greatest heat, from about ten till four o' clock, till the seed come up: and the sowings should be repeated every week; but as in summer these herbs soon become very hot tasted, to have them perfectly young and tender, it is advisable to repeat the sowings every four or five days in very hot weather.

The sowings are to be performed in shallow flat drills, as observed in the *Spring Sowing*, in the open ground, the seed sowed very thick and but lightly covered with earth, for the reasons formerly given.

And in very dry weather give daily waterings both before and after the plants begin to appear.

Autumn and Winter Culture.

From September to January, February, or March, is to be understood for the *Autumn and Winter Culture* of Small Sallading, the first part of which time it may be obtained in the open ground; but as soon as the cold weather sets in, it must be raised under glasses, and in hot-beds occasionally.

We may continue sowing in the open ground all September and October, also, often, the greater part of November in mild seasons; observing, that until towards the middle of October we may sow them in any open situation, but from the middle or latter end of October, and in November, the sowings must be on warm south-borders, still performing the sowings in shallow drills; and in cold nights bestow a covering of mats, or hand-glasses, &c. repeating the sowings every week, or ten days, or a fortnight, as occasion requires.

But when the cold weather commences in November, &c. it is adviseable to use garden-frames and lights, or hand, or bell-glasses, chusing a spot of light, rich ground in a sunny situation, sowing the seeds either in drills or all over the surface, according to the former directions, using the shelter of the frames and glasses as above; and thus you may raise plenty of Sallading, almost any time in winter, in mild weather; but when frost comes, recourse must be had to hot-beds.

However, in default of hot-beds to raise a constant supply all winter, it may be obtained great part of that season sowed in the natural earth, under good frames and lights, and other occasional covering, except just during the time of long, severe frosts, when the aid of hot-beds will be necessary: however, in order to raise them as well as possible during winter, without the constant aid of hot-beds, let some warm south-border of light rich earth, or other warm situation, be prepared for one, two, or more shallow garden-frames, raising it on the north side six inches, or more, so as to form it sloping to the sun, and having smoothed the surface, set on the frames, sinking the back-part thereof near a foot, that the whole surface of the earth may be within eight or ten inches of the glasses, for it is of much advantage to have the glasses tolerably close to the earth at this season, in order to receive the greater influence of the sun's heat, more especially when without hot-bed heat at bottom. The seed may here be sowed either in shallow flat drills, ranging from the back to the front of the frame, three inches asunder, as in the spring-sowings, or may be sowed all over the surface, patting it lightly down with the spade, and then just cover it with earth as thinly as possible; directly put on the lights and keep them close, and the plants will soon come up, repeating the sowings once a week or fortnight; and thus you may continue a constant succession of young Sallading most part of the winter; observing, in very cold weather, to line the frames closely about with dry litter; also in very cold nights, cover the glasses with mats or litter, though in very severe frosty weather, recourse must be had to the assistance of hot-beds, as below.

By aid of hot-beds a plentiful supply may be had in all weathers, making slender dung hot-beds for frames and glasses, as observed in the early spring-sowings, performing the

fowings also, as there directed, and manage the bed in the same manner, being careful in time of severe frosts to line the frame all around close with dry litter, covering the glasses also every night with the same material.

Thus far is the whole practical method of raising a plentiful supply of Small Sallading at all seasons of the year.

In gathering Small Sallading for use at all times of the year, let it always be used when quite young and in the seed-leaf, before they grow large and send forth rough leaves, more especially the mustard, radish, and other rough-leaved kinds; and when thus young, they may be cut up quite close to the ground, stalks and top together, all of which will then eat very tender and palatable.

But when they become large, and the rough leaves begin to advance apace, they are unfit for Sallading, as being rank and hot to the taste, so should be destroyed.

SMILAX, Rough Bindweed.

This genus consists principally of shrubby climbers, mostly of the ever-green tribe for the shrubbery, &c. rising with trailing and cirrhone-climbing stalks, mounting by support many feet high, adorned with heart-shaped, oval, and lanceolate leaves, in the different species, and apetalous, dioecious flowers.

Class and order, *Dioecia Hexandria*.

Characters.] CALIX, male and female flowers on separate plants, having bell-shaped, six-leaved, spreading cups, which in the females are deciduous.—COROLLA, no petals.—STAMINA, six filaments with oblong antheræ in the males.—PISTILLUM, an oval germen, three very small styles crowned by oblong, reflexed, downy stigmas in the females.—PERICARPIUM, a globular, trilocular berry, having two globular seeds.

There are twelve or thirteen species, mostly of a shrubby, climbing growth, some hardy, and some of tender nature; but it is principally some of the hardy kinds that are esteemed for culture in our gardens, having long trailing stalks, some armed with prickles, others are inermous, or unarmed, and mostly climb by means of cirrhi, or clasps, upon the adjacent trees and bushes, many feet high, which renders them proper furniture for thickets and wilderness quarters, &c. are all exotics from different foreign countries, both in Europe, Asia, and America; and the following are the most noted species, consisting of several shrubby, and one herba-

ceous kind for hardy plantations, and some shrubby sorts for the green-house, &c.

Hardy Kinds.

Of these sorts the first seven are shrubby, and the eighth is an herbaceous plant, all of the climbing tribe.

¹SMILAX *Aspera*.

Rough Spanish Smilax, or Common Rough Bindweed.] Rises with many long, slender, angular, trailing, prickly stalks, climbing ten or twelve feet high; heart-shaped, indented, prickly leaves, having nine longitudinal nerves, and small bunches of white flowers at the sides and ends of the branches, succeeded by round red berries.

Variety.] With black berries.

²SMILAX *Sarsaparilla*.

Sarsaparilla, or Peruvian Rough Bindweed.] Rises with angular, prickly, climbing stalks; oval, obtuse, trinervous, smooth leaves, and small bunches of white flowers at the axillas, succeeded by red berries.

³SMILAX *Tamnoides*.

Tamnoides Carolina Smilax, or Black-Briony-leaved Rough Bindweed.] Rises with taper, prickly, climbing stalks; large, oblong, heart-shaped, septemnervous, smooth leaves, and at the sides of the stalks loose bunches of whitish flowers, succeeded by black berries.

⁴SMILAX *Laurifolia*.

Bay-leaved Virginia Rough Bindweed.] Rises with taper, prickly, trailing, climbing stalks; oval-lanceolate, thick, stiff, smooth, trinervous leaves; and at the sides of the stalks round bunches of flowers, succeeded by black berries.

⁵SMILAX *Excelsa*.

Lofty-climbing Oriental Smilax.] Rises with angular prickly stalks, climbing to the tops of the highest trees; heart-shaped, smooth leaves, having nine nerves, and at the axillas, small bunches of whitish flowers succeeded by red berries.

⁶SMILAX *Lanceolata*.

Lanceolate Virginia Smilax.] Rises with taper inermous stalks; lanceolate, or spear-shaped, smooth leaves; and small clusters of flowers succeeded, by red berries.

⁷SMILAX *Rotundifolia*.

Round-leaved Canada Smilax.] Hath taper, prickly, climbing stalks; roundish, heart-shaped, acuminate, smooth leaves, having seven or five nerves; and small bunches of flowers, succeeded by small fruit.

⁸SMILAX *Herbacea*.

Herbaceous.

Herbaceous Virginia and Maryland Smilax.] Hath herbaceous, angular, inermous, climbing stalks; oval, septemnervous, smooth leaves; and umbellate bunches of flowers, succeeded by small berries.

Green-House Kinds.

They are ligneous climbers, like the others, but in winter require the shelter of a green-house.

¹*SMILAX China.*

China Rough Bindweed, or China Root.] Hath a thick, fleshy root; taper, prickly stalks, climbing near twenty feet high; oval, heart-shaped, quinquenervous, unarmed leaves; and at the axillas of the stalks bunches of small flowers, succeeded by red berries.

²*SMILAX Pseudo-China.*

Pseudo-China, or Bastard China Root.] Hath a large fleshy root; taper, inermous stalks, garnished with heart-shaped, inermous leaves, those on the branches being oblong, oval, and quinquenervous; and at the axillas bunches of small flowers, succeeded by red berries.

All the above ten species of *Smilax* flower mostly in June and July, which in all the sorts are apetalous, and male and female on separate plants, produced commonly in bunches from the sides of the branches, are small and make no ornamental appearance, and the female flowers are succeeded by berries, but they rarely ripen in England.

These plants are perennial in root, and all the woody kinds are durable in stalk, and mostly retain their leaves the year round.

Their roots are mostly composed of many fleshy fibres spreading widely on every side, sending up many trailing stalks, which in most sorts being furnished with cirrhi, they thereby mount upon any neighbouring support.

In their native soil abroad they grow naturally in woods and hedges, and thrive best under the shelter, shade, and drip of trees and bushes.

The hardy sorts therefore are singularly adapted as furniture for thickets, groves, wilderness, and wood works, planting them towards the front between the trees and shrubs, where they will run and spread very agreeably; exhibiting themselves as ever-greens all the year.

And the tender sorts being potted and placed in the green-house collection, allow-

ing them support to climb upon, they will effect a proper diversity.

Method of Propagation.

First the hardy kinds.—They are propagated by slipping the roots, by layers and by seed.

By slipping the Roots.—Many stalks rising from the roots widely around, the outer young ones of which may be readily slipped off with roots to each, which being performed in autumn or spring, may be planted either in nursery-rows for a year or two, or at once where they are to remain.

By Layers.—The stalks being layed in autumn, &c. they will be well rooted and fit for transplanting by autumn following.

By Seed.—This is commonly obtained from abroad by the seedsmen in the spring, which may be sowed, some in pots, and plunged in an hot-bed to forward their germination, otherwise they are apt to remain a year or more before they grow, and some may be sowed in the full ground near the shade of shrubs, &c. in a light, dry soil, in drills thinly, and covered about an inch and half deep, marking each row with a stick, because they will probably not come up till next year, giving however the common nursery care of weeding and watering the pots or beds, till the plants are come up, which should have occasional shelter in cold weather, and when two or three years old may be planted out, finally to remain.

Tender kinds.—Both the tender species may be propagated by layers, and by dividing the roots. Perform the laying in spring on the young shoots, which by autumn or spring following will be fit for potting off separately: and by roots, these being slipped in March or April, and the off-sets potted separately, they will soon take root; managing the whole as other woody exotics of the green-house.

SMYRNIUM, Alexanders.

The plants are large herbaceous biennials and perennials, one of which was formerly cultivated in the kitchen-garden as a culinary herb, used for stewing, &c. they all rise with large ternate and pinnated, many-lobed leaves from the root, and erect stalks, several feet high, crowned with umbels of flowers.

Class and order, Pentandria Digynia.

Characters.] *CALIX*, umbellate flowers, having the general umbel unequal and the smaller ones erect, without any involucre, and.

and scarcely visible cups.—COROLLA, a uniform, general umbel, composed of numerous florets, having each five spear-shaped petals.—STAMINA, five small filaments with simple antheræ.—PISTILLUM, a germen under each floret, two styles, having simple stigmas.—PERICARPIUM, none; a nearly globular, streaked, two-parted fruit, with two moon-shaped seeds.

There are five species, four biennials, and one perennial, mostly plants of but little merit; one sort, however, a biennial, being formerly in estimation as a culinary herb, we will exhibit its description and mode of culture, &c.

SMYRNIUM *Olusatrum*. (*Biennial*.)

Olusatrum, or common *Alexanders*] Hath a largish, downright, white, fibrated, biennial root, sending up several large, triternate, many-lobed leaves, and upright stalks, dividing and branching four or five feet high, garnished with ternate, serrated leaves, having foot stalks, and all the branches terminated by large umbels of white flowers.

This plant is a biennial, and is raised commonly from seed, which rising in spring with large leaves, remains till spring following, then shoots up stalks for seed, and perishes in autumn after.

The whole plant is of a strong, warm, somewhat aromatic nature.

It being blanched like celery is then fit for use as a culinary plant, and is also used for medicine without blanching, its leaves and seeds being used for that purpose.

It is propagated by seed sowed in the spring in any light soil and open situation, in shallow drills, fifteen or eighteen inches asunder; and when the plants are come up two or three inches high, thin them to six or eight inches distance in the rows, to give them room to shoot up strong, when earth must be drawn up about them; but in spring following, as they will shoot out again vigorously, let some earth be hoed up close about each plant, and in three or four weeks they will be blanched for use.

SOIL, see EARTH, COMPOST, DUNG, MANURE, &c.

SOLANUM Night-shade, comprehending the Love-Apple and Potatoe.

This remarkable genus furnishes many herbaceous and shrubby plants for ornament and use, consisting of annuals and shrubby perennials for adorning the pleasure ground, green-house, and stove collections, and eminent herbaceous culinary plants; some being

long trailers, others are of erect growth, garnished with pinnated and simple leaves in the different species, and all the sorts adorned with small rotated, five-parted flowers, succeeded by roundish, soft, baccaceous fruit, of various shapes, sizes, and colours, in the several species, &c. being in some sorts as large as apples and eggs, in others like cherries, and in some as small as currants; sometimes exhibiting a singular and ornamental appearance, and in some sorts (*Love-Apple*) is also in estimation, as esculents for culinary purposes; but the most valuable of all the species of this genus, is that admirable esculent, *Solanum tuberosum*, or Potatoe, for its large, tuberous, edible root, which is obtained for use almost the year round.

Class and Order, *Pentandria Monogynia*.

Characters.] CALIX, is monophyllous, cut half-through into five acute segments, and is permanent.—COROLLA, is monopetalous and rotaceous, having a short tube below, with a large, spreading, plicated limb, dividing into five spreading, pointed segments.—STAMINA, five small connivent filaments, terminated by oblong, connivent antheræ.—PISTILLUM, a roundish germen, slender style longer than the stamina, having an obtuse stigma.—PERICARPIUM, a roundish bilocular fruit of the berry kind, punctuated at top, having a connivent fleshy receptacle, and is filled with many roundish compressed seeds.

To this genus *Solanum* is now added, the *Lycopersicon*, or Love-Apple, the *Melongena*, or Egg-Plant, and the *Potatoe*; they being found to be all of the Night-shade tribe, both in the characters and quality, which, according to Linnæus, is supposed to be more or less poisonous, not excepting the Potatoe, though in a very small degree; and may be said to be the wholesomest of all the sorts of Night-shade, there being about thirty different species, ten or twelve of which are cultivated in the English gardens for variety and use; consisting of some herbaceous annuals, and one shrubby perennial for the pleasure-garden, &c. a few shrubby exotics for the green house and stove, and herbaceous annuals and perennials for the kitchen-garden.

Annual Kinds for the Pleasure-ground.

The principal sorts are the Love-Apple and Egg-Plant, there being many other annual sorts of less note; some are common weeds in

in our gardens, particularly the common black-berried Night-shade, comprehending many varieties; however the most material annuals under this head are the following.

¹*SOLANUM Lycopersicon.*

Lycopersicon, or Wolf's Peach, commonly called Love-Apple, or Tomatos.] Rises with strong, herbaceous, unarmed, procumbent stalks, branching numerously six or eight feet long; large, pinnated, rank-scented leaves, of four or five pair of cut lobes, and an odd one; and simple racemous clusters of small yellow flowers at the axillas, succeeded by large, roundish, compressed, furrowed, soft, red fruit.

Varieties are] Common large, furrowed-fruited Love-Apple.—Cherry-fruited Love-Apple, having smooth, round, red fruit the size of large cherries,—Yellow cherry-fruited,—Scentless leaved,—Burnet-leaved.

This species and varieties are all of large trailing growth, and flower in June, July, and August, and the fruit ripens in September and October, when they appear both ornamental, and are fit for culinary uses, particularly the common large-fruited kind, which is in high estimation in some families for improving soups, also for stewing, and sauces, &c. for which purposes they are highly valued by the Spaniards and Portuguese in particular, by which people they are commonly called *Tomatos*: so that this species is employed both as an esculent and ornamental plant, and in both cases its chief merit is in the fruit.

It is an annual in this country, whatever it may be in its native soil, which is the hot parts of America, but is hardy enough to succeed here in the open air in summer, being previously raised in hot-beds, thence transplanted; and as being of very rampant trailing growth, require the support of walls, pales, or stakes, which should also be in a sunny situation, otherwise the fruit will not ripen freely.

²*SOLANUM Æthiopicum.*

Æthiopian hard-fruited Love-Apple.] Rises with erect, smooth, herbaceous stalks, dividing and branching half a yard high; garnished with oval repand-angular leaves, and drooping pedunculi from the sides of the branches, each bearing one white flower, succeeded by round, striated, firm, red fruit.

³*SOLANUM Melongena.*

Melongena, or Egg-fruited Night-shade, commonly called Egg-plant.] Rises with an erect, thick, firm, herbaceous stalk, branching

erectly two or three feet high; large, oval oblong, entire, downy leaves; and blue flowers singly from the sides of the branches, having prickly cups, succeeded by large, oval, egg-like, pendulous fruit of different colours in the varieties.

Varieties are] Common white-fruited Egg-plant, having large, white, fleshy fruit, the size and shape of a very large egg,—purple-fruited Egg-plant,—red-fruited—yellow-fruited,—prickly-fruited, &c.

This singular species and varieties are all of upright firm growth, branching and forming full heads, well garnished with fine large leaves, and flowers in June and July, and the fruit attains perfection in August and September, being all of the large egg-shape; but the white-fruited sort is in most esteem as a curiosity, for its very great resemblance to a hen's or swan's egg, effecting a singular appearance as they grow on the plants; and in some warm countries in the south of Europe they are very commonly eaten and are accounted wholesome: in England, however, they are not at all relished, so that the plants are cultivated only as a curiosity, and as such highly merit culture in the pleasure-garden.

These plants being natives of Asia, Africa, and the warm parts of America, require to be raised and forwarded in hot-beds in this country.

⁴*SOLANUM Nigrum.*

Common Black Night-shade.] Rises with an upright herbaceous stalks, branching a yard, or two or three feet high, oval, angular-indented leaves; and from the sides of the branches roundish nodding umbels of white flowers, succeeded by black, and other coloured berries in the varieties.

This common black Night-shade, is chiefly used as a medicinal plant; it grows wild in gardens, fields, and dung-hills in England, and most parts of the world, often becoming a troublesome weed, so is rarely cultivated; it, however, comprehends several varieties which were formerly considered as distinct species, but prove to belong all to the *Solanum Nigrum*, having all oval leaves, and nodding umbels, and are sometimes cultivated in gardens for variety.

The different Varieties are] Common black-berried Night-shade, as above,—large, upright, spreading, black Night-shade,—greenish-yellow berried,—red-berried,—villose yellow berried, with taper hairy branches and

and angular somewhat hairy leaves,—Guinea black-cherry-berried, with angular dentated branches, and smooth entire leaves,—Virginia, upright, black berried, with angular branches, and repand smooth leaves,—Jew's black Night-shade, with prickly branches. All of which produce their flowers in nodding umbels in summer, succeeded by umbellate clusters of berries in autumn.

All the above four species and varieties are herbaceous annuals, being mostly but of one summer's duration, particularly the Love-apples and *Melongena*; but several of the varieties of the *Solanum Nigrum* will often continue all winter if potted and placed in the green-house: however, an annual supply of all the four species must be raised every spring from seed; remarking, that the first three species, being exotics from hot countries of Asia, Africa, and America, require to be raised in hot-beds in spring for transplantation into the full air in summer; but the fourth sort being hardy, most of its varieties may be raised in the open ground.

Most of the above annuals may be employed in the pleasure-ground for variety, more particularly the Love-apples and Egg-plants; and the former also as culinary plants for their fruit, as aforesaid; but the *Melongena*, or Egg-plant, having great singularity in their egg-like fruit, merit a place in every curious garden: as to the *Solanum Nigrum*, or Black Night-shade, the best sorts may be admitted in large gardens to encrease the variety; and if some are also planted in pots, trained up straight, and placed in the green-house in October, they will remain green all winter, and exhibit an agreeable variety during that season, with their umbels of ripe fruit.

Their Propagation and Culture.

As to the propagation and culture of all these annual Night-shades, they are all easily raised from seed sowed annually in the spring; the three tender kinds in hot-beds, for transplantation in May or June, and the hardy sorts (*Solanum Nigrum*) in the open ground.

For the tender kinds, Love-apples, and Egg-plant, prepare a moderate hot-bed in March or April, as for other tender annuals, covered with a frame and lights, and moulded over with light rich earth six inches thick, or may sow them in any hot bed already made for other plants, such as cucumber beds, &c. provided there is room, sowing the seeds either in the earth of the bed in

small drills, or in pots and plunged in the hot-bed; and when the plants come up indulge them with fresh air and occasional waterings, in common with the other plants of the hot-bed, and thin them where they stand too thick, that they may have room to gather some strength previous to their transplantation; or if they are pricked out upon a fresh hot-bed, it will forward them considerably, which is more particularly necessary for the Egg-plants.

Observe, however, of the Love-apple kinds, in particular, that towards the latter end of May, when the plants are from about four to six or seven inches high, and the season is become tolerably warm and settled, plant them out finally in the full ground on some warm border, placing them singly at some considerable distance, on account of their large spreading growth; planting some also against a south fence, &c. to have the full sun, as well as for the advantage of training their trailing branches along regularly; for unless they have support they will trail upon the ground, and overspread the neighbouring plants, and not ripen their fruit; but being trained against some sunny fence like a wall-tree, or to a treillage or stout stakes, they will shew themselves to proper advantage, and ripen their fruit more early and perfect, and exhibit it more ornamentally.

But as to the *Melongenas*, they being raised as above in a hot-bed, it is also advisable to forward them as much as possible by the farther aid of one or more hot-beds, in order to run the plants up to a large growth, and exhibit themselves and fruit in full size and perfection.

Therefore when those seedlings are one or two inches high, having a fresh hot bed ready, prick out a quantity about four inches asunder, or plant some in small pots singly, and plunge them in the hot-bed, giving water and occasional shade, from the sun till they are fresh-rooted, repeating the waterings as occasion requires, and admit a due portion of fresh air every mild day by tilting the upper end of the lights; then, when the plants have been forwarded about a month in this bed, some may be thinned out with balls to their roots, and placed upon another hot-bed six or eight inches asunder, managing them as before, it will still forward them more considerably to a large stature for flowering and fruiting in perfection; observing, as they advance in height to raise the frame by

by degrees in proportion: likewise in their advanced growth, and as the warm season approaches, begin to harden them gradually to the open air, in fine days; and towards the middle or latter end of June, the plants being grown tall and strong, and the season become warm and settled, they should be removed into the full air, finally to remain: when those growing in the earth of the bed may be taken up, with balls of earth to the roots, planting them either in the borders or in pots; and those already in pots may be shifted into larger, and placed to adorn fore-courts, or any other conspicuous compartments, where they will effect a curious variety, with their egg-shaped fruit, all the autumn season.

The hardy kinds.—As to the hardy kinds, consisting of several varieties, (*Annuals*) all the offspring of the *Solanum Nigrum*, or Common Black Nightshade, are easily raised from seed; sowed in the latter end of March or in April, mostly in a bed or border of light earth, separately, either broad-cast on the surface, and raked in, or in shallow drills, thinly, not more than half an inch deep; and the plants when about three inches high, planted out about the borders and in pots: or they may be sowed at once where they are to remain, in patches in the different compartments, and the plants afterwards thinned to one in each place; or may sow some of the foreign varieties, in particular, in a hot bed, to raise and forward them more effectually, planting them out as above.—Thus, in either method, they will arrive to a flowering state in July, and produce their umbels of berries in autumn; observing, if designed to keep any of the more curious sorts as long as possible, they must be potted, and placed in the green-house, where they will remain all winter.

Hardy Shrubby Kinds.

There is one hardy shrubby species, comprehending some varieties; mostly wild climbing plants of the hedges, in England and most parts of Europe, but are retained in many gardens for variety.

⁵SOLANUM Dulcamara.

Dulcamara, Bitter-sweet, or Climbing Woody Nightshade.] Rises with long, flexuous, inermous, woody stalks, climbing, by support, many feet high; oblong, pointed leaves, with the upper ones halbert-shaped; and cymose clusters of small blue flowers, succeeded by bunches of small, oval, red berries.

Varieties.] Common blue-flowered, as above—White-flowered—Variegated white striped-leaved—Gold striped-leaved—African thick-leaved, formerly ranged as a distinct species, but proves to be only a variety of the *Solanum Dulcamara*.

They all flower in June, July, and August, and the berries ripen soon after.

All the varieties of this species are of the climbing tribe, and durable in root and stem, &c. but deciduous in leaf. The common sort grows wild in field-hedges, in most parts of Europe, climbing over the neighbour-plants; and is often cultivated in shrubberies as a climber, in assemblage with the variegated sorts.—But the variegated kinds are in most esteem as garden plants, for the beauty of their elegant striped leaves, and are therefore much employed as climbers.

As to the African thick-leaved variety, it being tender, requires to be potted, and treated as a green-house plant.

All the hardy varieties, however, *i. e.* the common, and two striped kinds, &c. will grow freely almost any where in the full ground: the common sort, in particular, will succeed also in any close place, so is often planted even in towns and cities; and all these sorts, considered as climbers, are proper furniture for shrubberies, wilderness quarters, groves, and thickets, and to run over arbours; allowing them support of stakes, or placed to climb upon bushes, &c. Allow the variegated sorts generally a dry and rather poor soil, otherwise they will be in danger of growing too vigorous, and become plain.—They are easily propagated by layers and cuttings, in autumn, winter, or spring, and they will all be well rooted by autumn following, and fit for transplantation, either in nursery rows, or at once, where they are to remain.

Shrubby Green-house Kinds.

There are many tender shrubby sorts, of the quality of green-house plants, some of which are retained in our gardens for ornament and variety; which being exotics from warm countries, must be kept in pots, in order for moving to shelter in winter.

⁶SOLANUM Pseudo-capsicum.

Bastard Capsicum; commonly called *Amomum Plinii*, or *Winter Cherry*.] Rises with a shrubby, upright, inermous, green stalk, branching numerously and erectly all around, three or four feet high, forming a regular head,

head, garnished with narrow, spear-shaped, repandous leaves; and white flowers, in sessile umbels, or singly from the sides of the branches, succeeded by many beautiful red berries, like cherries, appearing very ornamental all winter.

Variety] With yellow berries.

Both the varieties are beautiful shrubby plants from Madeira, flowering in June, July, and August, and the fruit ripens in autumn and winter, which in both sorts are of the shape and size of common cherries, but not eatable; appearing very beautiful all the winter season; effecting a pretty variety in the green-house collection.

⁷*SOLANUM Sodomeum.*

Apple of Sodom, Pomum Amoris, or Shrubby African Love-Apple.] Rises with a shrubby, prickly stalk, branching two or three feet high, having the branches also armed with spines; ob-oval, pinnatifid-sinuated, prickly leaves, with the segments obtuse; and large blue flowers in bunches, from the sides of the branches, having prickly calyces; succeeded by large, round, compressed, yellow fruit, the size of a small apple, ripening in winter.

⁸*SOLANUM Indicum.*

Indian Nightshade.] Rises with a shrubby, prickly stem, branching two or three feet high, with the branches also armed with spines; wedge-shaped, angular, entire, somewhat-hairy leaves, prickly on both sides; and longish bunches of blue flowers at the sides of the branches, succeeded by round, golden-yellow fruit, the size of cherries; ripening in winter.

⁹*SOLANUM Verbascifolium.*

Verbascum-leaved, Downy, American Nightshade.] Rises with a shrubby, inermous stem, branching a yard high, or more; oval, entire, downy leaves, and compound umbels of flowers at the axillas of the branches, succeeded by small round berries.

These four tender shrubby species flower here in June, July, and August; and they all ripen their fruit abundantly in the end of autumn, and in winter.

They are all of shrubby growth, durable in root, stem, and branches, and retain their leaves most part of the year. The first two sorts are the most noted of these kinds in the English gardens, but the first sort most of all; however all the four sorts merit culture, to increase the variety in the green-house collection, as they will form a pretty diversity, both in their flowers and fruit, most part of

the year, but particularly in autumn and winter, when the fruit ripens, which exhibits a very ornamental appearance.

Their Propagation and Culture.

The propagation of all these green-house sorts is principally by seed in a hot-bed in the spring, and the seed may be obtained at the nurseries and seed-shops.

Therefore, in March or April, prepare some pots of rich light earth, in which sow the seed thinly, and cover it half an inch deep, and plunge the pots in any common hot-bed, under frames and lights, giving frequent refreshments of water, and the plants will soon come up, when a due portion of fresh air must be admitted daily, together with repetitions of moderate waterings occasionally; and when the seedlings are about two or three inches high, it is advisable to prick them out upon another hot-bed; which being framed, and earthed six or eight inches deep, plant the seedlings therein, six inches apart, giving water, and shade from the sun, till rooted. It is also eligible to prick some out in small pots singly, and plunge them also in a hot-bed; observing in both methods to give frequent waterings, and admit a large share of fresh air every day, by tilting the lights; and as the warm weather advances, harden the plants gradually to the full air, so as towards the middle or end of June they may bear to be fully exposed; at which time those not potted may be taken up with balls, and planted in proper pots (twenty-fours) and the already potted plants shifted into larger, placing them in the shade for a week or fortnight; managing them afterwards as other shrubby exotics of the green-house.

Tender Shrubby Kinds for the Hot House.

Under this head is comprised four or five tender shrubby exotics, from the warm parts of America and Africa, and require the aid of a stove to preserve them in this country; so are kept in pots, and placed in that department for variety.

¹⁰*SOLANUM Igneum.*

Fiery-thorned American Nightshade.] Rises with a shrubby prickly stem, branching a yard or more high, closely armed with fiery-red thorns; spear-shaped, acuminate leaves, revolute at the base; and simple racemous clusters of white flowers at the sides of the branches, succeeded by red, cherry-like berries.

¹¹So.

¹¹SOLANUM *Guineense*.

Guinea Nightshade.] Rises with a shrubby, inermous stem, branching five or six feet high, having also smooth branches; oval, entire leaves, and very slender lateral peduncles, terminated by branches of small white flowers, succeeded by round yellow berries.

¹²SOLANUM *Tomentosum*.

Tomentose Ethiopian Nightshade.] Rises with a shrubby, tomentose, prickly stem, branching two or three feet high, armed with acerose prickles; heart-shaped, repandous, inermous, tomentose, or woolly leaves; and bunches of small flowers, succeeded by golden-yellow fruit, the size of gooseberries.

This species is remarkable for its tomentose property, it being almost totally covered with down.

¹³SOLANUM *Bahamense*.

Bahama Nightshade.] Rises with a shrubby, prickly stem, branching several feet high; spear-shaped, obtuse, repandous leaves, reflexed in the margin; and simple clusters of blue flowers at the sides of the branches, succeeded by red berries.

¹⁴SOLANUM *Trilobatum*.

Trilobate Jamaica Nightshade.] Rises with a slender, shrubby, prickly stem, branching five or six feet high; wedge-shaped, mostly trilobate smooth leaves, and some with five lobes; and small white flowers singly, succeeded by small fruit, the size of elder-berries.

All these tender shrubby *Solanums* for the stove collections, must be always kept in pots of light rich earth, and retained most part of the year in the stove, except about two or three months in the heat of summer; and thus they will flower annually, and ripen plenty of fruit.

They are all propagated by seed in a hot-bed in the spring; sowing it in pots of light earth, and plunge them in the hot-bed, and when the plants are come up two or three inches high, prick them separately in small pots, which plunge also in the hot-bed or bark-bed, and manage them afterwards as other shrubby exotics of the stove.

Their propagation may also be tried by cuttings; planting them in pots, plunge them in the bark-bed, and cover them close down with a hand-glass.

Hardy, Herbaceous, Esculent Kinds.

Under this head is comprised only one species, Potatoe; having already mentioned

a culinary species, among the tender annual kinds, viz. *Lycopersicon*, or Love-Apple, sometimes cultivated as an esculent, as well as an ornamental plant; but the most valuable esculent in this genus is the *Tuberous-rooted Nightshade*, commonly called Potatoe, comprehending several varieties, all of hardy temperature, and which, for their fine, large, eatable roots, may be said to be the most profitable culinary esculents in the world, as they may be obtained in great plenty the year round, and are almost universally admired by all ranks of people; and in many countries are become a principal article of food among the common people. But Linnæus, and some other modern botanists, as we formerly remarked, considering all the Nightshades of the lurid tribe of plants, *i. e.* such whose foliage, &c. assume a disagreeable green colour, of a forbidding aspect, thereby suppose the plants to be more or less poisonous; not excepting the Potatoe, though in a very small degree: and it is said a dullness attends the constant eating of them, and sometimes a griping, more especially when any considerable quantity is boiled and eaten in broth or soups, before the juice has been previously boiled out in another water. However, when Potatoes are thoroughly well boiled, roasted, or baked, they prove a very palatable and wholesome root, either to eat alone, or as sauce to flesh-meat, though roasting is probably the wholesomest way of using them. They however are cooked in various ways, in all of which they are exceedingly profitable for the service of a family.

The botanists admit of only one real species of the Potatoe, comprehending several varieties, as above observed, differing in the form, colour, and other properties of the root, and colour of the flowers.

¹⁵SOLANUM *Tuberosum*.

Tuberous-rooted Peruvian Nightshade, commonly called Potatoe.] Hath a tuberous root, emitting numerous fibres, productive of many large roundish and oblongish, fleshy, edible tubers; and immediately from the root rise herbaceous, flexuose, smooth stalks, somewhat erectly, a yard long, garnished with large pinnated leaves, of several pair of entire lobes; and terminated by subdivided peduncles, supporting bunches of small purple, or white flowers, in the different varieties, succeeded by roundish fruit, furnishing ripe seed in autumn.

It is the tubers of the root only of this plant that is eatable; the fruit, the product of the stalk, is never used.

Varieties.] It comprehends two principal varieties, viz.—Red-rooted Potatoe, generally producing reddish or purple flowers.—White-rooted Potatoe, commonly bearing white flowers.—Each of which principal varieties comprise several intermediate ones, such as — Round-red — Oblong-red — Pale-red — Rough-red — Smooth-red — Red and white — Early dwarf-red — Kidney-shaped white Potatoe — Round-white — Large oblong-white — Large red-ended white kidney-shaped — Large conglomerated American Potatoe, being generally clustered together considerably, each root or tuber attaining a prodigious large size, being in estimation principally for feeding cattle.

This species *Solanum Tuberosum* is a native of Peru, where the natives of the country commonly call it *Batatas*, and hence it here derived the European name Potatoe.

It may be considered both as an annual and perennial; observing in the first case, that the same individual root is only of one year's duration; for being planted in spring, each root sends out numerous off-sets, becoming proper Potatoes by autumn following, at which time the said parent roots will be almost totally decayed; hence it becomes an annual: but in the second case, the off-sets of the parent root remaining found till the next year, when they also furnish an abundant supply of off-sets, hereby the species is perpetuated in great abundance from year to year, and becomes of a perennial nature: remarking, however, that a fresh plantation must be performed every spring.

With respect to the properties of the different varieties of Potatoes for use, there is no very material difference; though the red sorts were formerly in greatest esteem, and, in our opinion, are the best for eating; though of late years, the Potatoe cultivators about London, who raise prodigious quantities annually, generally prefer the oblong white sorts, particularly a sort they call by the cant name of Red-nosed Kidney; it being a large, oblongish, whitish Potatoe, reddish at one end, and is esteemed to be both more prolific in its produce, more saleable in market, as well as the finest eating Potatoe of any; therefore they have almost totally neglected the culture of the fine large red Potatoes, which by many are held superior to the others for richness of flavour. It is, however, proper to cultivate a due share of the best sorts of each kind, all of which are raised in great plenty by the roots, either planted whole, or cut into several pieces, and

being planted in the spring, each multiplies into a large cluster of new Potatoes, fit for use the following autumn or winter; though sometimes the early sorts will be fit to take up for use in June or the beginning of July, of the size of large walnuts; so continue lifting them up by degrees as they are wanted till October or November, when the main crops will be full grown; at which period of growth, and not before, they are in the highest perfection; and the largest full-grown Potatoes are considerably finer eating than the small ones, which generally eat hard, livery, and watery, entirely devoid of that fine rich mealy flavour peculiar to large full-grown Potatoes, nor are they altogether so wholesome for general use.

Observations on their general Culture.

Potatoes may be obtained for use plentifully almost the year round; the early sorts being planted forward in the spring, they often afford tolerable little Potatoes fit to take up in June or July following, as formerly observed, especially in the rich warm grounds about London, where they generally begin taking them up for market in June, before they are a quarter grown, or as soon as they attain the size of good walnuts, and thence continue taking them up occasionally till the general crops arrive to full growth in the latter end of October; both because early Potatoes fetch an extra price, and that the ground may be cleared time enough for the reception of some other crops, such as turneps, coleworts, cabbage, favoys, &c. for winter, in which there is a double advantage; suffering, however, the greater part of the main crops of Potatoes to remain untouched until the end of October, or beginning of November, to attain mature growth, and thereby obtain the roots in their ultimate perfection, both for eating and long keeping: for Potatoes that are taken up before they have had their full growth, consequently prove inferior both in size, quality, and duration; but being permitted to continue growing till autumn, about the latter end of October, or beginning of November, as above said, till the stalks or haulm, begin to decay, the roots will be arrived to full maturity; and being then taken out of the ground in due time, and housed in some close dry apartment, they will keep in good perfection for eating all winter and spring, until the arrival of the new crops next summer.

All the varieties of Potatoes may be cultivated with success in any open situation, both in gardens and the open fields; very considerable quantities being now cultivated in the fields round London, and most other great towns, for the supply of markets, they proving very beneficial crops; and the main crops being cleared off in due time, the ground is often sowed with wheat, which generally succeeds remarkably well immediately after Potatoes.

As to the American Cluster-Potatoe, it generally grows to a vast size, in a conglomerated or clustered manner, each often weighing several pounds, and at present is cultivated chiefly for feeding of cattle. Its culture is the same as the common sorts, only requires more room to grow.

All the sorts delight in a moderately light dry soil, and open situation; and if enriched with dung, the greater success may be expected.

The plants are propagated most commonly by the root, *i. e.* the Potatoe, either whole or cut in pieces, each forming a proper set or plant; and being planted in March or April, in rows, two or three feet asunder, twelve or eighteen inches apart in the rows, and five or six inches deep, they come up in a month or six weeks after, requiring no other culture than a little hoeing to kill the weeds, and loosen the ground; and each set will thus multiply into a large cluster, just within the surface of the earth, attaining full growth the same year, fit to dig up for use in autumn, continuing good till summer following. See their *General Method of Propagation, &c.*

As Potatoes, therefore, are the most profitable of all our esculent roots, and being of easy culture, their cultivation merits universal attention for the service of families of all ranks, and are now in many places cultivated to great advantage for the supply of the markets, where they always prove a very saleable commodity.

In the markets Potatoes are sold both by weight and measure; but in London they are always sold by weight, at from two or three to four or five shillings the hundred, of six score: though the early ones, at first coming in, sell at a much higher rate; sometimes at the enormous price of two guineas per hundred in Covent-Garden market: they, however, quickly fall to the afore mentioned prices; and when they come in plentifully, they being generally sorted into three sizes,

ware, middlings, and chats; the former being the largest, they fetch the best price, and the others sell in proportion; all of which are retailed accordingly to the consumers at from a penny, or three farthings, to one farthing per pound.

General Method and Season of Propagation, proper Soil, &c. and Method of Planting.

The general method of propagating Potatoes is by the root or Potatoe itself, being the tuberos part of the root, and the only part to plant for propagation; and which may be planted either whole or cut in pieces, as formerly mentioned, and each planted separately at certain distances, directed below.—Potatoes may also be raised from seed, by way of experiment, to gain new varieties: by roots, however, is the only eligible method of propagation for general culture.

First by Roots.—As we above observed, the propagation by roots being by planting the tubers or Potatoes themselves, a proper quantity should be procured in due time in the spring for planting, observing always to procure the finest moderately large roots of the respective varieties for sets; though some use only the small chats, for planting; but we have always found that the middlings, or full-sized roots, generally yielded the largest Potatoes in return. Likewise observe, that it is of much importance to change your sets; that is, not always continue using those of your own crops, or of any other place constantly, but every two or three years at most procure a fresh parcel of some different distant growth, which will be found of great advantage, both in preventing a degeneracy, and in the goodness of the crops; remarking likewise, the sets may either be planted whole, or each cut in three or four pieces, preserving one or more eyes, or buds, to each cutting: they, however, should not be cut until just the time for planting.

The general season for planting Potatoes is from about the middle or latter end of February to the middle of April; remarking that the early sorts, &c. for forward crops, may be planted in the latter end of February, and early in March, in a dry warm situation; but for the general crops, March, and the first fortnight in April is the most eligible planting season; especially in moist land, as if planted earlier, and much wet should succeed, it might rot the sets, more particularly if cuttings: though in cases of necessity, where the

the ground is not ready, &c. Potatoes may be planted any time in April, or even in May, and will yield tolerable crops by October: however, those planted towards the middle or latter end of March, and early in April, are principally to be depended on for the main crops to attain due perfection.

Observe, as to the proper situation and soil in which to plant Potatoes, always allow them an open exposure, and tolerably dry situation; and as to soil, they are generally the most prosperous in a moderately light pliable ground; none better than a good sandy loam, in which they commonly yield fine crops: however, chuse any the most convenient moderately-light land, of a pliant free-working nature, and not wet; and the ground may either be such as has been in constant digging or ploughing before, or in grass-sward; observing in the former case, that if the ground be rather poor, be sure to bestow a good coat of dung, to be dug or ploughed in; but if the ground is in sward, and a fresh good soil, hardly any dung will be required; for the sward being digged or ploughed in properly, it generally answers the purpose of dung the first year, and is commonly productive of excellent crops.

The ground may either be digged or ploughed for the reception of the plants. The digging is generally the most practicable for gardens, and being performed one full spade deep will be sufficient; and as to the ploughing, this is commonly practised for large quantities in fields, being careful to plough the full depth; and, if not grass-ground, if ploughed again cross-ways it will be the greater advantage; or in stubborn land, two or three ploughings may be necessary to divide and break the soil properly, performing the first ploughing in autumn or beginning of winter, and cross-ploughed in spring towards the time for planting; and if after the ploughing, the surface is rough and stubborn, a good harrowing will be proper for the better reception of the plants.

Then with respect to the method and order of planting the Potatoes, they are planted either with a dibble, or holed in with a spade, or drilled in with an hoe, &c. as hereafter explained, in rows two feet asunder at least, twelve or fifteen inches distant in each row, and five or six inches deep, as directed below; remarking, however, the American clustered Potatoe in particular should generally be allowed a yard

distance between the rows; but some advise all the sorts to be planted at that distance in the field-culture, in order both to admit of horse-hoeing frequently between the rows, to loosen the surface of the earth effectually, and to allow a greater scope for growth, and a more free admission of sun and free air, to give all the chance possible for improving the size of the Potatoes.

But as to the particular methods of planting them, the following six are occasionally practised, &c. dibble-planting, drill-planting, holeing-in-planting, furrow-planting, trenching-in-planting, and bedding-in-planting; but the three or four former are the most eligible methods.

By Dibble-planting.—This may be performed either with a common large garden-dibble, blunted at the bottom, making holes therewith five or six inches deep, at the distance before mentioned, dropping one set in each hole as you go on, and striking the earth over them; but those who plant large quantities in fields, have generally a Potatoe-dibble for this purpose, being a large long dibble, about a yard in length, with a cross handle at top for both hands, having the lower end thick, blunt, and shod with iron six or eight inches up, the iron being also obtuse or blunted at the lower end; and about six inches from the bottom is fixed an iron shoulder, both for the convenience of a tread for using the feet occasionally to thrust it into the ground, and that by striking it in always to the shoulder, it makes the holes all an equal depth. With this instrument one person is employed in making the holes a foot or more asunder, whilst another follows close after, and immediately drops one Potatoe-set in each hole; then the ground is well raked or harrowed over to cover in all the holes properly. But in gardens, where only a few are planted for family use, the dibbling-in the sets may be performed with any common garden-dibble, thick and blunt at the lower end as hinted above; and one person may both dibble the holes and drop the sets as he goes on, striking the earth in upon them with the dibble, and afterwards rake the ground.—See the articles DIBBLE and PLANTING.

By Drill-planting.—Drills may be formed either with a large hoe or plough, two feet asunder, and six inches deep, in which drop the sets, a foot asunder, and cover them in with the earth equally the depth of the drill.

By

By Holeing-in-planting.—This is performed with a spade. A man having a light handy spade, and beginning at one end of the line, takes out a spit of earth, forms a small aperture about six inches deep, another person directly following after drops a set in the hole, the earth of the next spit immediately covers it up, and so on to the end.

By Furrow-planting.—This is sometimes performed in fields, in very light pliable land, and is performed by dropping the sets in the furrow immediately after the plough, and the ploughing of the next furrow turns the earth in upon the sets of the first; and in another furrow, two feet from this, drop another row of sets, which are covered in as above; and so on till the whole is finished.

By Trenching-in.—This is sometimes practised in gardens, in light ground, by way of experiment, and is effected as they proceed in digging or trenching the ground, being trenched in the common way, each trench two spades wide, and one spade deep, placing one row of Potatoes in each trench. Beginning, therefore, at one end of the ground, open a trench the proper width and depth, as above, then paring in the top of the next trench deeply, together with some good dung in the bottom of the first, levelling it evenly; and upon which lay the Potatoe-sets in a row along the middle a foot or more asunder: then digging along the second trench a moderate spade deep, turning the earth thereof into the first trench, over the sets, six or seven inches deep; this done, dung the bottom of the next open trench, and proceed with the digging and planting as before; and thus continue trench and trench to the end.

By Bedding-in.—This is sometimes done in low wetish land, for the sake of raising the beds, and sinking the alleys deep enough to drain off the too copious moisture, and is thus performed. The ground is divided into four, five, or six-foot wide beds, with alleys two or three feet wide between bed and bed; and the beds being digged, the Potatoe-sets may then be placed upon the surface in rows lengthwise; and then dig out the alleys a spade deep, casting the earth thereof over the sets about six inches thick; or the alleys may be first digged out to raise the beds, and the sets then planted with a dibble in the common method. Thus, by either of these methods, in wet ground, the alleys being sunk, and the beds raised, the alleys drain off the re-

dundant moisture, which might rot the sets before they begin to sprout.

But in all the above methods of planting Potatoes, those of dibbling-in, drilling, and holeing-in are the most in practice; and about London, the dibbling them in being the most expeditious, is the most commonly practised.

Culture of the Plants.

The Potatoes being however planted in either of the above methods, it now remains to speak of their future management; observing, therefore, they are to remain in the same place to grow to perfection; and as to culture, when the plants come up, and weeds begin to over-run the ground, they require only two or three hoeings to kill the weeds, and loosen the surface of the soil; the Potatoes generally coming up in about a month or five or six weeks after planting, being accompanied by numerous weeds, which should be hoed down in due time, before they grow large and overspread the surface, or over-top the plants; performing the hoeings generally in dry weather by broad-hoeing, or in fields by horse-hoeing, for the greater expedition; repeating the hoeings according as the future growth of weeds shall render it necessary, as well as to stir and loosen the surface of the ground about and between the plants, which will also prove very beneficial culture in improving their general growth. After, however, two good hoeings, the plants will generally be advanced sufficiently out of the reach of weeds, and become so spreading as to prevent their future progress, when no farther care will be required till the Potatoes are arrived to perfection. In hoeing Potatoes, many take the pains to hoe up a ridge of earth close to each side of every row of plants in the first or second hoeing, to strengthen their growth more effectually, and render them more prolific; as the bottom of the stalks so landed up, generally emitting roots in the earth that become productive of Potatoes the same as the general roots.—Thus far is the principal culture of Potatoes, they hardly ever requiring any farther care after June and July; but the crops, however, continue growing till autumn, and the main crops in particular, which you design shall stand to have their full growth, will continue growing till October, or till the haulm begins to decay in November, when the Potatoes being full-grown, they should be then wholly

wholly taken up before they are attacked by frost, and deposited in some dry apartment for keeping: remarking, however, as we before observed, that new Potatoes being by many required as forward in the season as possible; and sometimes the early sorts, growing in warm rich land, afford young Potatoes in June as big as walnuts, or little apples, in which case may begin to dig up some for present use; though only a few should be taken up at a time at this early season, just by way of rarity, not more than can be used in a day or two; for, being not a quarter grown, they will not keep long out of the ground; if even but a few days, they will neither boil, bake, or eat well; but may continue thus taking up a few at a time occasionally, so as to have a constant supply from June or July, till the perfection of the general crops in October and November.

Method of digging them up, and housing them for Winter and Spring Use.

As to the method of digging up the Potatoes for use, it is most commonly performed in gardens with a three-tined fork; and sometimes in fields they are ploughed up for the sake of making quicker dispatch for considerable quantities; but the forking them up, however, makes the cleanest work; and there are Potatoe-forks for the purpose, being made with flat tines, blunted at the point, and fixed upon a spade-handle. Most country smiths know how to make them; and are sold at the iron-mongers, and at many of the nurseries.

Previous to the digging up the Potatoes, the haulm should be cleared away for some considerable space close to the ground, turning it off in heaps, to clear the surface, for the greater convenience and expedition in digging, &c. then, if intended to fork them up, proceed by first opening a trench along one end of the ground one spade wide and deep, and then go on with the digging up the Potatoes the same depth, having large baskets, &c. placed, in which to throw them as they are dug up, being careful to dig all the ground regularly along spit and spit, the bottom part of the haulm remaining to each root will be some direction for placing the fork, turning the spits clean up before you into the open trench, and pick the Potatoes of each plant clean out, great and small, as you go on, and put them in the baskets. As you advance with the digging, continue clearing off the

haulm upon the dug ground in heaps, which may afterwards be burned to serve as manure, and thus proceed till the whole is dugged up; taking the opportunity, whilst dry, to house those directly that are intended for long keeping.

The taking up Potatoes by the plough is performed by ploughing the ground in the common method, which turns up the Potatoes very expeditiously to the top, several hands following immediately after to pick them clean out.

Immediately after the Potatoes are taken up, pick out all the cut and bruised ones; likewise may sort out the small chats from the large ware, and then let the main crops for keeping be housed, when they are perfectly dry, in some dry close place, well defended from the free air, wet, and frost, in which the Potatoes may be deposited in a large heap, if brought in quite dry; observing, that if a sufficient quantity of dry light earth, or sand, is strewed between them from time to time, as they are housed, it will prove advantageous in keeping them in greater perfection, covering the whole, however, at last with a good thickness of dry straw, and keep the apartment close shut; for the more the external air is excluded, the better they will keep.

Thus the main crops of Potatoes being taken up and housed, they will remain sound all winter and spring, till the arrival of new ones next summer, as we before remarked, provided they are well defended, as above, from wet and frost.

It is however to be remarked, that at the approach of spring, towards March and April, many of the Potatoes will vegetate and sprout forth in the house, so should be turned over occasionally, and still continue a thick covering of straw, to exclude the external air as much as possible, and they will keep till June.

Raising them from Seed.

By Seed.—This is very rarely practised, because their great encrease by roots render it unnecessary; besides, the propagation by roots is considerably the most expeditious and effectual method: so that raising Potatoes from seed is only sometimes practised by way of experiment, and to try to gain new varieties. However, when this is intended, let some of the first flowering-plants be marked for seed, which gather in autumn when full ripe, and in March or April following sow it in some light

light soil, in an open situation, in shallow drills, a foot asunder; and when the plants come up, keep them clear from weeds till autumn, when, about the end of October or November, take up the roots, select the finest and largest, which preserve in sand till spring, then plant them in the common way, and by autumn following they will have made proper encrease, and attain full perfection; and you will then judge of their properties.

SOLIDAGO, Golden-Rod. (*Virga Aurea*.)

It comprizes many herbaceous flowery perennials, of upright growth, for adorning the pleasure ground; rising with numerous erect stalks, from one to several feet high, garnished mostly with narrow, spear-shaped, and oval leaves, and the top terminated by numerous spikes of small, compound, radiated, golden-yellow flowers.

Class and order. *Syngenesia Polygamia Superflua*.

Characters.] **CALIX**, a compound radiated flower, having an oblong imbricated cup, composed of several narrow connivent scales.—**COROLLA**, is compound and radiated, having numerous funnel-shaped, quinque-dentate, hermaphrodite florets in the disc, and tongue-shaped, tridentate, female florets in the radius.—**STAMINA**, five short hair-like filaments, with cylindric antheræ.—**PISTILLUM**, an oblong germen, filiforme style, crowned with a bifid stigma, and in the females two revolute stigmas.—**PERICARPIUM**, none.—**SEMEN**, a single oblong seed in each floret.

The species of Golden-Rod were formerly greatly extended, but now reduced by Linnaeus to twelve species, comprehending numerous varieties, one of which is a native of England and most parts of Europe, and most of the others are from North America; but all the sorts are very hardy, and retained in our gardens as flowering-plants.

They are all fibrous-rooted perennials, that renew their stalks annually in spring.

The species are,

¹**SOLIDAGO Virga Aurea.**

Virga Aurea, or Common Golden Rod.] Rises with several angular, slender, almost flexuose stems, from one to two feet high, garnished with narrow spear-shaped leaves, and divide upward into paniculated, erect, clustered spikes of golden-yellow flowers, in August and September.

Varieties.] Tallest Purple-stalked.—Broad sawed-leaved,—Narrow slightly-sawed leaved,—Low-stalked, &c.—Each of which was formerly ranged as a distinct species, but prove to be varieties only of the common *Virga Aurea*.

This species and varieties grow naturally in many parts of England, &c.

²**SOLIDAGO Canadensis.**

Canada Rough-leaved Golden Rod.] Rises with several round smooth stems, two feet high; narrow, rough, trinervous, slightly-ferrated leaves, and terminated by corymbose panicles, with recurved spikes of ascendent yellow flowers, appearing in July and August.

³**SOLIDAGO Altissima.**

Tallest, Late-blowing, American Golden Rod.] Rises with numerous round smooth stems, four or five feet high; spear-shaped, sawed, enervous, or unveined leaves, and terminated at top by large corymbose panicles, with recurved spikes of ascendent yellow flowers, in September and October.

Varieties.] There are many varieties of this species, differing somewhat from one another, but distinguishing themselves specifically, as this sort, by their tallish growth, enervous or unveined leaves, and large corymbose-paniculated recurved clusters of flowers, as above, flowering late in autumn.

⁴**SOLIDAGO Latifolia.**

Broad-leaved Canada Golden Rod.] Rises with erect angular stalks, two or three feet high; broad, oval, sharp-pointed, sawed leaves, and lateral single spikes of yellow flowers, appearing in September.

⁵**SOLIDAGO Flexicaulis.**

Flexicaulous Canada Golden Rod, with a Fig-wort Leaf.] Rises with a slender flexuose stalk, two feet high; oval, sharp-pointed, serrated leaves, lateral single spikes of pale-yellow flowers, in September.

⁶**SOLIDAGO Mexicana.**

Mexican Golden Rod.] Rises with oblique brown stalks, a foot and half high; spear-shaped entire leaves, and erect, branching, leafy peduncles, bearing yellow flowers, in August and September.

⁷**SOLIDAGO Cæsia.**

Smooth Maryland Golden Rod.] Rises with naked smooth stems, a foot and half high; garnished with narrow, spear-shaped, acute-pointed leaves, and terminated by corymbose panicles, with thick upper spikes of yellow flowers, appearing in September.

***SOLIDAGO Lateriflora.**

Lateral-flowered American Golden Rod.] Rises with small stalks a foot and half high; narrow, unferrated, pointed leaves, and the stalks branching laterally below, almost from bottom to top, in floriferous spikes, shortening, and terminating upwards, in corymbose panicles, with recurved clusters of yellow flowers, in September.

⁹SOLIDAGO Rigida.

Rigid or Stiff-leaved, Pennsylvania Golden Rod.] Rises with many upright stalks, two feet high, branching alternately; oval, stiff, rough, cauline leaves, and the stalks and branches terminated by a corymbus of yellow flowers, in September.

¹⁰SOLIDAGO Novboracensis.

New York Golden Rod.] Hath oval, oblong, radical leaves, having foot-stalks, branching naked stalks, near two feet high, garnished with very small leaves, and terminated by panicles of bright-yellow flowers, in September.

¹¹SOLIDAGO Minuta.

Least Pyrenean Golden Rod.] Rises with small single stalks, only about a foot high, spear-shaped entire leaves, and the pedunculi rising at the axillas, each supporting but one yellow flower, appearing in August.

¹²SOLIDAGO Sempervirens.

Sempervirent, Fleshy-leaved, New York, Golden Rod.] Rises with several upright reddish stalks, five or six feet high; spear-shaped, almost fleshy, smooth leaves, with roughish margins, and the stalks terminated by large corymbose panicles of bright-yellow flowers, appearing in October, and great part of the winter, in mild seasons.

All these twelve species of *Solidago* are very hardy fibrous-rooted perennials, of great duration in root, but mostly annual in stalk, which rising in spring, many from each root, arrive to a flowering state in autumn; all the stalks adorned upward with long spikes of numerous small flowers, exhibiting a very conspicuous bloom a month or six weeks, and totally decay to the root in winter.

They are so hardy as to prosper in any common soil and situation, with but very little trouble in their culture.

Considered, therefore, as garden furniture, they are proper autumnal ornaments for almost every compartment of the pleasure ground, and should be introduced in assemblage in all large borders, shrubberies, wilderness quarters, and the borders of wood-

walks, &c. where, being judiciously distributed, at eligible distances, they will effect a grand autumnal bloom for three or four months, in the different sorts, as each root generally sends up numerous stems close together, often forming a large bush, adorned above with numerous long panicles of golden-yellow flowers, which, though separately small, they being numerous and closely placed in each spike, are remarkably conspicuous and ornamental, particularly all the foreign kinds.

The flowers are universally compound and radiated, composed each of numerous hermaphrodite and female florets, as expressed in the *Characters*.

Most of these plants increase exceedingly by the roots, a small slip of which often multiplies, in one season, into a large bunch; and several of the sorts being apt to spread considerably, require to be slipped, or cut in all round every year or two, to keep them within proper bounds.

They should, therefore, be always planted at some considerable distance from one another, and not too near small plants.

Method of Propagation and Culture.

The propagation of all the sorts is effected with great facility, by slipping or parting the roots in autumn and winter, soon after their stalks decay, or early in spring, before they begin to shoot; not slip them too small, and may be planted at once where they are designed to flower, and will all blow in good perfection the following summer and autumn.

All the culture they require is, to have the decayed stems cut down every winter; and when the roots have increased considerably spreading, should be slipped or cut in all around, as before observed.

SORBUS. Sorb, or Service-tree.

This genus is composed of noted deciduous trees, of middling stature, principally for ornamental plantations; growing from twenty to thirty or forty feet high, or more, adorned with beautiful pinnated leaves of many pair of folioles, and pentapetalous flowers in umbellate clusters, towards the ends of the branches, succeeded by large bunches of red berries.

Class and order, Icosandria Tryginia.

Characters.] **CALIX**, is monophyllous, concave-spreading, quinque-dentate, and permanent.—**COROLLA**, five roundish concave petals, inserted into the calix.—**STAMINA**, about

about twenty awl-shaped filaments, having roundish antheræ.—PISTILLUM, a germen under the receptacle, three slender styles, and capitated stigmas.—PERICARPIUM, a roundish, soft, umbilicated berry, containing three oblong cartilaginous seeds.

There are only three species in this genus; all three hardy deciduous trees; the first of which is a native of England, &c. the others are exotics from the continent of Europe and other foreign parts; the two first sorts, in particular, are common in most of the nurseries and eminent plantations.

¹*SORBUS Aucuparia.*

Bird's Service, commonly called Wild Service-tree, or Mountain Ash; also, sometimes, Quicken Tree, Quick Beam, or Roan Tree.] Rises with a straight upright stem, and regular branching head, twenty or thirty feet high, or more, covered with a smooth greyish-brown bark; pinnated leaves of eight or ten pair of long, narrow, serrated folioles, and an odd one; smooth on both sides, and large umbellate clusters of white flowers at the sides and ends of the branches, succeeded by clusters of fine red berries, ripe in autumn and winter.

Variety.] Yellow-striped leaved.

This species grow wild in many parts of this island, on mountainous places, woods, and hedge-rows, often arriving to the growth of timber, and is admitted in most ornamental plantations, for the beauty of its growth, foliage, flowers, and fruit; the latter, in particular, being produced in numerous large red bunches all over the tree, exhibit a fine appearance in autumn and winter, till devoured by the birds, especially the blackbird and thrush, which are so allured by these fruit, as to flock from all parts and feed on them voraciously, but are not fit for domestic or household use.

²*SORBUS Domestica.*

Household, or cultivated Service-Tree, with eatable fruit.] Grows with an upright stem, branching thirty or forty feet high, or more, having a brownish bark, and the young shoots in summer covered with a mealy down; pinnated leaves of eight or ten pair of broadish deeply-serrated lobes and an odd one, downy underneath, and large umbellate clusters of white flowers at the sides and ends of the branches, succeeded by bunches of large, fleshy, edible red fruit, of various shapes and sizes in the varieties.

Varieties of the fruit are] With Apple-shaped fruit—Pear-shaped fruit—Oval-fruited—With turbinate fruit—Compressed-fruited, &c.—all of which ripen in autumn; generally two, three, or four on a bunch, being sometimes as big as little apples and pears, but are rarely palatable till they begin to assume a state of corruption.

This tree is a native of the southern warm parts of Europe, where its fruit is in high esteem to serve up in deserts, and is cultivated here, in many of our gardens, both as a fruit-tree, and to diversify hardy plantations.

³*SORBUS Hybrida.*

Hybridaceous, or Mongrel Service-Tree, of Gothland—supposed a mongrel between the *Sorbus Aucuparia* and *Cratægus Aria*.] Grows twenty or thirty feet high; half-pinnated leaves, very downy underneath, and clusters of white flowers, succeeded by bunches of roundish red berries in autumn.

These three trees are all of the deciduous tribe, and of hardy temperature, growing freely in any of our open plantations in any common soil and situation; their foliage and flowering is generally pretty forward, commonly expanding their leaves in April, being all of the beautiful, pinnated, many-lobed kind; and the flowers appear in May and June, composed each of five small petals, but many growing together in clusters are conspicuous enough; succeeded by baccaeous fruit, ripening in August, September, and October, often remaining on the trees after the fall of the leaf, particularly the *Sorbus Aucuparia*, which often retains its fruit all winter, or till devoured by the birds, as before remarked.

As to the merit of these trees in gardening, they all demand culture in every eminent shrubbery and other hardy plantations; being introduced as standards, they will effect a fine variety in assemblage, with their elegant pinnated leaves and clusters of flowers and fruit: the Wild Service, particularly, should be plentifully interspersed in all extensive shrubberies, for the singularity of their numerous clusters of berries in autumn and winter, which also prove food to encourage plenty of singing birds in the plantations.

But the *Sorbus Aucuparia* may also be introduced as a forest tree in timber plantations, being mostly all heart is valued for many purposes.

And some of the *Sorbus Domestica* may also be employed as fruit-trees in the garden and orchard; some being trained as standards, others as dwarfs, and against walls and in espaliers for variety, training them, nearly as directed for pears and apples.

They are raised in all the public nurseries for sale, particularly the first two sorts.

Method of Propagation, &c.

They are all easily propagated in abundance, by seed, in the open ground, also by layers, though the seedlings generally make the handsomest plants.

By Seed.—The berries or seeds ripen abundantly in autumn, which is the proper time for sowing them, being careful to have them perfectly ripened, gathering them in due time before devoured by the birds, and prepare to sow them as soon after they are gathered as possible. For their reception, dig a spot of lightish ground in the nursery, and divide it into four-feet-wide beds, in which sow the berries, either in drills an inch deep, or bed them in, by raking the earth from off the bed near that depth; then sowing the seed all over the surface, cover them all an equal depth, with the earth drawn off, as above, for that purpose: some of them will probably rise the following spring, they, however, frequently remain till the second spring before they come up; observing, in either case, that, in spring following, when the seedlings are a year old, they should be planted out in nursery rows, to remain till they acquire a proper size for final transplantation.

Sometimes, in order to forward the germination of these seeds, particularly the *Sorbus Domestica*, we sow them in large pots, which being sheltered under a frame in winter, and in spring plunged in a hot-bed, will bring up the plants the same year fit for transplantation in nursery-rows the following autumn.

By Layers.—Having some of the trees, while young, cut down near the ground, it will force out lower shoots, which being layed, in the common way, in autumn and spring, they will readily emit roots, and be fit for transplantation in nursery-rows in one year. This is also a certain method to continue any particular variety.

But the cultivated Service in particular, when designed to raise a quantity of fruit-trees for their fruit, they should generally be pro-

pagated by grafting or budding the choicer-fruited kinds upon stocks, of any of the sorts of *Sorbus*, raised from seeds or layers as above; they will also take upon pear-stocks.

SOUP HERBS.

Many sorts of herbaceous vegetables, of the culinary tribe, are in great estimation for the improvement of soups, &c. a list of which, collected under this head, will serve to assist the memory in furnishing the garden with the proper sorts; remarking, that under the denomination of Soup Herbs, may also be understood all the sorts of Pot-herbs used occasionally in soups and broths, &c.

In some families a great variety of Soup or Pot-herbs are occasionally required, and in others a few only of the common sorts are used, so that every kitchen garden ought to be furnished accordingly with the proper sorts.

The following is, therefore, a list of the principal sorts occasionally used as Soup-herbs, &c. several of which, however, are also employed in various other culinary uses, fallads, &c. as well as for soups. Celery—Endive—Leeks—Lettuce—Spinach—Green and White Beet—Chard Beet—Orach—Borage—Bugloss—Chervil—Sorrel—Parsley—Coriander—Pot-Marigold—Thyme—Winter Savory—Summer Savory—Pot or Winter Marjoram—Sweet Marjoram—Spear-Mint—Basil—Love-Apple, or Tomatoes.

In all of which, except the Marigold and Love-Apple, the leaves are the only useful parts; but in the Marigold the flowers are the only part used, and in Love-Apple the fruit; remarking, likewise, that all the sorts, but the last two of the list, (Basil and Love-Apple) are of a hardy temperature, and may be easily raised in the natural ground; and the greater part are biennials and annuals, that require to be annually raised from seed; but the Thyme, Winter Savory, Pot or Winter Marjoram, Sorrel, and Mint, are perennials of many years duration, being raised some both by seeds and slips, others principally by slips; and the Basil and Love-Apple, being tender annuals, require to be raised from seed in a hot-bed. See the culture of all the sorts under their respective genera.

But the most prevailing Soup or Pot-herbs, of the above list, for general use are, Celery, Endive, Leeks, Spinach, Beet, Parsley, Chervil, Thyme, Marjoram, Savory, and Spear-Mint.

However, the particular merit of the different sorts, together with the proper culture,

ure, is fully exhibited, each under its proper head.

SOWING OF SEEDS.

Different methods of sowing Seeds are practised occasionally, as different sorts require, and according to different practitioners; such as broad-cast sowing and raking-in, —drill-sowing, —bedding-in-sowing, &c.

BROAD-CAST SOWING, &c.—This is the most common and expeditious method of sowing in practice, particularly in the kitchen-garden, both for crops to remain, and for transplantation, and is performed by sowing the Seed with a spreading cast evenly all over the surface of the ground, either in one continued plat, or divided into beds, which is immediately raked with a large rake to bury all the seeds a due depth in the earth, some requiring to be raked in as light as possible, others half an inch or an inch or more deep, according to their size, &c.

In preparing for this method of sowing, the ground is previously digged in the common way, making the surface level with the spade as you go on; no occasion, however, to break the surface very fine, nor rake it, only forming it even with the spade, as just observed, and leave it a little roughish, more or less, in proportion to the size of the Seeds, that they may be more effectually buried a proper depth for germination; observing, for the general part, that the ground should be sowed whilst fresh stirred, before the surface is rendered either too dry and hard by the sun and wind, or made wet by rain; but when it is so moderately dry as not to clog to the feet or rake, and that it will readily fall under the rake in raking in the Seed.

All Sowing should generally be performed in dry weather, more particularly all early sowing in winter and spring; but in hot weather, in summer and autumn, it may often be eligible to take advantage of sowing immediately after a shower or moderate rain.

After, however, having digged the ground as above, the Seeds are then to be sowed broad-cast, all over the surface, either in one continued plat, and raked in as before remarked; or the ground may be previously stepped out into four or five feet wide beds, with small alleys between bed and bed, then sowing the seed on each bed separately, or may first sow the ground broad-cast, as above, and afterwards mark it out in beds, as aforesaid. The laying out the ground in beds may, in some cases, be the most eligible way; such

for example, if wet ground that cannot bear treading, we can stand in the alleys both to sow the Seed and rake it in, without trampling the beds; and when weeding and watering becomes necessary, can also stand in the alleys to perform those works; likewise to cull and gather the produce, or transplant where necessary; and that no ground may be lost, we may in some cases have succeeding crops coming forward in the alleys; however, in kitchen-gardens, where ground is scarce, or that it is of importance to make the most of every inch of ground, as well as use the most expeditious method of sowing possible; the broad-cast sowing all over the surface, in one continued plat, as above observed, may be the more eligible practice, especially in large grounds, as is the method of most of the kitchen-gardeners about London, for the main crops of carrots, parsneps, turneps, onions, leeks, Spanish lettuce, radishes, &c.

As to the method of sowing the Seed in the Broad-cast way, it is effected occasionally both with an open and locked hand.

In the former case (sowing open-handed) it is performed by delivering the Seeds with an open hand, and broad-spreading cast, as practised in sowing corn in the open fields, previously stepping out the ground in breaks, or certain widths, as a guide to sow with the greater regularity; so proceeding with the sowing along each space with a regular step and cast, giving the hand a proper sweeping cant forward, fully expanded at the delivery of the Seeds, making them spread abroad evenly in every part; and thus proceed up one space and down another till finished; which method of Broad-cast sowing is practised in large kitchen grounds in sowing any considerable space in one continued plat, as observed above.

But in the other case, (sowing close-handed,) that in narrow beds, when we intend sowing them bed and bed separately, or narrow borders, and other small plats of ground, we commonly sow or deliver the Seeds with a locked or close hand, discharging them from between the fore-finger and thumb, opening or pinching the thumb more or less, according to the size and nature of the Seeds, and thickness they require to be sowed, giving the hand a sort of jerking turn, or cant forward at the delivery, to cause the seeds to spread regularly.

As soon as the seeds are sowed in either of the above methods of sowing, let them be directly

S O W

directly raked in before the surface of the ground is rendered either too dry by the sun and wind, or made wet by rain if likely to happen; observe as below.

But previous to the raking in the Seed sowed on the surface, as above, that if the ground is tolerably light and dry, and a dry season, it is of importance immediately after sowing to tread them in evenly by treading the ground all over regularly with the feet, it being more particularly necessary in light loose ground in the Broad-cast Sowing all over the surface, in one continued plat, which not only settles the Seeds, so as to be more effectually buried all an eligible regular depth in the raking, but also settles the ground evenly in every part, as that when we stand thereon to rake in the Seeds, the feet will not sink in holes, as would be the case at every step in light ground, if not previously trodden; it also prevents the drought of the spring from penetrating too freely: but, indeed, if the ground is laid out in beds, we may either tread in the Seed or not, as we may readily stand in the alleys to rake them in without trampling the beds, which, in wetish ground in particular, may be the more eligible practice; however, even in the sowing in beds immediately on the surface, as above, in light loose soils, with a dry surface and dry season, it is eligible enough to tread in the Seed, previous to raking the ground after sowing; which work of treading in the Seeds, in both the above methods of sowing, is performed with the feet nearly close together, taking short regular steps, treading the surface lightly all over, once in a place, with but small spaces between the steppings.

Directly after the treading in the Seeds, as above, let the ground be regularly raked over to cover all the seeds effectually a proper depth, using a large wide-teethed rake for this purpose (see RAKE); being careful to rake very regularly, not to draw the earth and Seed in heaps, raking only once or twice in a place, which is generally sufficient, especially where the Seed has been previously trodden down in the above manner; taking care, however, to perform it so effectually as to bury all the Seeds properly: and as you advance in the raking, trim off lightly all large stones and rubbish.

Observing some Seeds require to be raked in as lightly as possible, such as all the very

S O W

small Seeds; others require to be a quarter or half an inch deep, others a whole inch or more, so use smaller or larger rakes accordingly. See RAKE.

The above methods of Broad-cast Sowing and raking in, may be practised to numerous sorts of Seeds, particularly the greater part of the esculents of the kitchen garden: numerous flower seeds and others, as is generally hinted in their culture, and, being the most ready and expeditious mode of Sowing, is proper for general practice, especially in extensive grounds, except for some particular sorts of Seeds that require to be sowed either in drills or by bedding in, as directed below, which is particularized in treating of the respective plants in their proper places.

But in many of the extensive kitchen-gardens in the vicinity of London, &c. where they sow large tracts of ground at once, instead of raking in the Seed sowed in the Broad-cast way immediately on the surface, they, for the sake of expedition and cheapness, have light short-tined harrows to draw with men, with which they harrow in the Seeds; and sometimes they afterwards roll the ground with a light wooden roller to close and smooth the surface, in order to cover the seeds more effectually, performing it when the surface is a little dried so as not to adhere to the roller.

And in the large garden-farms in fields, where they commonly plow and harrow the ground for the reception of seeds, they practise only the broad-cast Sowing in continued tracts for almost all their esculent seeds, except for peas, beans, and kidney-beans, and not generally bestow the work of treading down the seeds as before mentioned; but the ground being prepared by ploughing, and afterwards rough-harrowed, to smooth the surface moderately, the seeds are then sowed broad-cast, in the spreading open-handed manner, and then harrowed in either with a light horse-harrow, or harrowed in with men for particular crops; then roll the surface afterwards with a wooden roller drawn also by horses, &c. to smooth the surface, as aforesaid.

DRILL SOWING.—This method of Sowing is necessary for many sorts of seeds, both esculents, flowers, and tree and shrub kinds in the nursery, both for the plants to remain where sowed, and for transplantation, and is performed by drawing drills with an hoe, from a quarter or half an inch, to
two

two or three inches deep, according to the sizes and sorts of seeds, which being sowed evenly along the bottom of the drill, the earth is drawn evenly over them with a hoe or rake, the depths as above, and the surface lightly raked smooth.

As to the sorts of seeds that may be sowed in drills, numerous sorts may with propriety be sowed in that method, but is particularly eligible for many large kinds, such as peas, kidney-beans; and many large kinds of tree and shrub seeds, nuts and berries; it being not only the most ready method of committing those large seeds to the ground the proper depth; but being sowed in rows at a distance, best suits the nature of growth of many sorts of plants, and their method of culture. Many kinds of small seeds are the most conveniently sowed and cultivated in drills, such as several of the kitchen-garden plants, as parsley, chervil, coriander, all the sorts of small-salading, and sometimes spinach, beet, &c. also some of the aromatics when designed as edgings, such as thyme, savory, hyssop, and the like, which is generally mentioned in treating of their culture; likewise many sorts of flower-seeds are the most commodiously sowed in drills, both when designed for transplantation, and sometimes to remain, as is exhibited under their proper genera: but many of the tree and shrub seeds, in particular, are the most conveniently sowed in drills, all of which is properly noticed under the genera of the respective sorts.

For by Sowing in Drills to all such plants as admit of it, prove not only an eligible method of sowing to bury all the seeds regularly an equal depth; but the drills being at some distance from one another, admits the sun, air, and rains more effectually to the plants, and gives them a greater scope of growth, than such as are sown broad-cast, or promiscuously all over the surface, but admits also of introducing a hoe between the drills to hoe down weeds and loosen the soil, which always proves a most beneficial culture.

The method of drill-sowing is both easy and expeditious: in gardens it is performed by drawing the drills with a common drawing-hoe, large or small, in proportion to the sorts of seeds to be sowed, generally setting a line as a guide to draw the drills straight, which, as before observed, are drawn of different depths, from a quarter or half an inch to two

or three deep, as the sorts and sizes of seed may require, and at proportionable distances, from three or four inches to so many feet, according to the nature of the plants; all of which particulars are always noted in the culture of the respective sorts, under their proper heads.

The general method of drawing of drills for the reception of seeds, is with a common drawing-hoe, as before noticed, sometimes with a large hoe, and sometimes a middling or small hoe, according to the size of the drill required, size and nature of the seeds; drawing the drill sometimes with the corner of the hoe, especially for larger seeds, and sometimes with the edge of the hoe flat-ways or horizontally; but for large seeds, such as peas, kidney-beans, many of the nut kinds, and other large seeds both of trees, shrubs, and herbaceous plants, require a deep angular drill, drawn with the corner of the hoe, turning the face or edge close to the line, so draw the drill along with an angular bottom evenly the depth required, the earth remaining close along the side of the drill, ready for turning in again over the seeds; but where flat or shallow drills are required for smaller seeds, it may, in many cases, be more eligible to draw the drill with the hoe flat-ways, holding the edge in a horizontal position, as before observed, drawing the drill along with a flat bottom evenly the whole width of the hoe the proper depth, suitable to the sorts of seeds intended to be so sowed.

Sometimes, when very small drills are required, we draw them with the end of the fingers, or with the end of a small flat stick.

Having, however, drawn the drills in either of the above methods, the seeds should generally be sowed and covered in directly, if the ground is dry and in good order; but if the soil is wet, especially at an early season, it may be proper to suffer the drills to lie open exposed to the sun and air an hour or two, or more, to dry a little, particularly for tender seeds in early sowings, as just above observed, such as kidney-beans, &c.

As to the method of sowing in the drills, it is performed for the general part with a locked or close hand, discharging the seeds from between the fore-finger and thumb, as before related, scattering the seeds evenly along the bottom of the drill, some sorts requiring

quiring to be sowed thinly just along the middle, such as in the angular drills drawn corner-ways of the hoe, for peas and many other larger seeds; also sometimes for smaller seeds when intended for edgings; but in the shallow flat-bottomed drills it is generally intended for the seeds to be scattered evenly the whole width of the drill, thicker or thinner according to the nature of growth of their respective plants, proper hints of which are generally exhibited in their culture, observing to cover in the seeds generally as soon as sowed, as already hinted, raking or hoeing the earth evenly over them, just the depth of the drills.

Remarking, the work of covering the earth in the drills over the seeds may be performed occasionally both with the rake, hoe, and feet; but the rake or hoe is the most eligible for general practice, drawing the earth evenly into the drills a regular depth fully to the depth of the drill, whether deep or shallow; however as to peas, kidney-beans, and the like larger seeds in large drills at wide distances, they are often covered in with the feet, by slipping them lightly along each side of the drill alternately, turning the earth evenly in over the seeds; but generally for all small seeds in close drills it is proper to cover in with the rake or hoe, sometimes using the teeth of the rake, and sometimes the back occasionally, as it shall seem most convenient; observing that as soon as the drills are covered in by either of the methods, let the surface be lightly trimmed along with the rake to smooth it and clear off large stones, &c.

In the husbandry Drill Sowing, the drills are generally drawn with the drill-plow by horses, which effects that work very expeditiously; and for some seeds is so contrived as to draw the drills, sow the seed, and cover them in all at the same time.

BEDDING-IN SOWING.—This is a sort of broad-cast Sowing in beds, because the seeds are sowed all over the surface, but in a different way from the above mentioned: in this method the ground being digged and formed into four or five-foot-wide beds, with alleys, a spade width or more between bed and bed, and the earth being drawn off the top of the bed with a rake or spade half an inch or an inch or more deep into the alleys, the seed is then sowed all over the surface of the bed; which done, the earth in

the alleys is immediately drawn or cast over the bed again over the seeds the same depth, and the surface raked smooth.

This mode of sowing is often practised in the nurseries, but not very frequently in kitchen-gardens, except in some parts of the North; it is not so expeditious as the broad-cast Sowing, but is nevertheless very proper for many sorts of small seeds, and many sorts of the tree and shrub kind, being a very regular method of Sowing so as to cover all the seeds an equal depth, and is performed two or three different ways, such as by rake, by spade, and by sifting.

In performing it by the rake, the ground is digged in the common way, raking the surface as you go on, afterwards marking it out into four-foot-wide beds with moderate alleys between bed and bed; then having a large rake, turning the teeth upward, and with the back thereof shove the earth evenly from off the surface of the bed, a quarter or half an inch, an inch or more deep, as may be required, into the opposite alley in a little ridge all the way along; this done, directly sow the seed evenly all over the surface of the bed, then directly with the rake turned the right way, teeth downward, proceed to draw the ridge of earth out of the alley over the seed, striking the teeth of the rake smartly down on the farther side of the ridge of earth, and drawing it toward with a kind of jerk, make the earth spread evenly over the seed quite from one side of the bed to the other, proceeding in that manner, drawing one stroke after another to the end of the bed; then proceed to the next in the same manner, and so continue bed and bed till all is finished; then with a light rake gently trim the surface smooth and clear of stones.

In some places this method is practised almost in general in sowing all sorts of small seeds, and by many preferred as a very eligible method of broad-cast sowing, so as to cover all the seeds evenly an equal depth; it, however, is not near so expeditious for large grounds as the common broad-cast Sowing and raking in.

However, those that are used to this method of Sowing rid it off a great pace; sometimes two or three hands being employed on the same work, one shoves the earth from off the bed, another follows immediately after with the sowing, and this followed directly

directly by a third, draws the earth over the seed, and so proceed bed and bed.

But nearly the same method of Sowing is also sometimes performed with the rake and spade together, particularly in the nurseries, when intended to sow any larger seeds a good depth, using the rake to shove or rake the earth from off the bed, into the alleys; or if it cannot be conveniently performed with the rake a proper depth, it is effected with the spade, trimming or paring the earth evenly off the surface, half one way, half the other, into the alleys; then sow the seeds all over the surface as before, and if they are of the larger berry, nut, or stone kind, or any other large seed, previous to covering them, press or pat them all evenly down into the earth, with the back of the spade; and then, either with the rake or spade, cover the earth out of the alleys evenly over them; though if it is a deep covering, especially if taken off with the spade, it is most eligible to use the same implement in returning it, being careful to spread it evenly to cover the seeds all equally a proper depth, smoothing the surface with the rake.

Another method sometimes practised in Bedding-in Sowing any common large seeds is, the ground being laid out in beds unraked, the seed is sowed on the surface, and with the rake strike it a little into the earth, then with the spade pare the alley, and cast the earth evenly over the bed, half an inch, or an inch or more deep, as may be required, and rake the surface even. This is also sometimes designedly practised in wet-tish ground, at an early season, when it does not readily admit of treading or raking. And by deepening the alleys, and raising the beds, it drains the moisture from the surface.

The method of Bedding-in Sowing, by sifting, as formerly mentioned, is sometimes practised for very small or light seeds of a more delicate nature, that require a very light covering of earth when sowed. So in order to bury them as shallow as possible, cover them in, by sifting fine earth over them out of a wire sieve. Previous to Sowing such seed, the surface of the bed, &c. is raked fine; then either shove the earth thinly off the surface of the bed with the back of the rake into the alley, making the surface as smooth as possible, and then sow the seed, and sift the earth in the alley

evenly over it, some very small sorts only just covered, not more than half a quarter or a quarter of an inch deep: or sometimes the surface being only raked as smooth as may be, without drawing off the earth as above; and may also smooth it with the back of the spade, then sow the seed, and let some fine earth from the alley, or some brought for the purpose, be sifted thinly over it, as just above-mentioned.

SPADE.

A Spade is the most useful garden implement for digging, and preparing the soil for the reception of all sorts of seeds and plants.

There are several sorts and sizes of spades occasionally used, though the common large digging-Spade is, in most places, almost commonly used for all kinds of digging and Spade-work, which however in many instances, cannot be so conveniently used as a middling or small Spade; it is therefore eligible for every good garden to be furnished with three different sizes of Spades, to suit every department of gardening the more commodiously, such as the common large digging Spade, for all common digging and Spade-work as above observed, and a middling, and a small Spade for digging particular narrow compartments, and digging between small plants closely placed in beds and borders, &c.—See each as below.

Common digging Spade, &c.—This is designed for all common digging, and trenching of ground, and all kinds of strong Spade-work; so is of the largest size, being generally from fourteen to sixteen inches long in the plate, and nine or ten broad, generally narrowing half an inch, or an inch less at the bottom. Though in some of the kitchen gardens about London, where the ground is light and deep, they use Spades full sixteen or eighteen inches long in the plate, especially the Battersea Spades; however, for the general part, a Spade of fourteen or fifteen inches, by nine wide, proves the most handy size for all common digging in every district of gardening: but as they are made of different sizes, from fourteen to sixteen or eighteen inches long in the plate, as aforesaid, so every one may suit himself according to the depth and nature of his soil, and method of working.

Middling Spade.—Being as to size, about a foot long in the plate, and seven or eight inches broad; which will prove very useful in digging any narrow compartments, and

between narrow rows of small plants; also in flower beds, and borders; likewise in stirring, and fresh earthing the surface of beds occasionally, between close-placed plants of long standing: planting and transplanting many sorts, both in the ground, and in pots, and for many other sorts of light Spade-work.

Small Spade.—The size ten or twelve inches long in the plate, and five or six wide, and is convenient in pointing up or flight digging, and fresh earthing the surface, between close rows of small plants, in beds and borders, &c. where none of the two former Spades can be readily introduced; likewise is useful in planting and potting many sorts of small plants, taking up small roots, and other light purposes occasionally.

Proper garden Spades have the plate wholly of iron, not above a quarter of an inch thick upward, growing gradually thinner from the middle downward; the tree or handle being generally of ash, about two feet, and a half long, and an inch and half thick, with a firm open handle at top, formed out of the solid wood, just big enough to admit of taking ready hold, one hand at top, and the other below.

Semicircular, or scooped Spade.—Besides the three sorts of Spades above mentioned, there is also another sort, having the plate made semicircular like a scooped garden-trowel, and is very useful in taking up plants with balls of earth, to preserve the ball more firmly about the roots.

All the sorts of Spades are sold by most of the nursery and seedsmen, and by the ironmongers; the prices being according to the sizes, from five shillings to half a crown; the common digging Spades generally from four to five shillings, the middling size ones three shillings and six-pence, and the small spades half a crown, or three shillings; so that the whole price of a set of spades is but trifling.

SPADICEUS *flos*, from *spadix*, a flower, or an aggregate of flowers, produced on that particular receptacle called a *spadix*, which is protruded from a sort of calix called a *spatha* or sheath, as in *Narcissus*, *Amaryllis*, snow-drop, &c. See **SPADIX**, **SPATHA**, and **SPATHACEÆ**.

Many of the bulbous and tuberous rooted tribe, produce Spadiceous Flowers, the principal of which are, *Amaryllis*, or lily daffodil, Guernsey lily, &c.—*Allium*, garlick,

onion, leek, &c.—*Crocus*, all the varieties.—*Colchicum*, meadow saffron.—*Narcissus*, daffodil; jonquils, &c.—*Galanthus*, snow-drop.—*Leucojum*, greater snow-drop.—*Arum*, wake-robin, &c.—*Calla*, Æthiopian Arum.—*Orchis*, fool-stones, &c.—*Satyrion*, bee-flower.—*Ophrys*, twy-blade.—*Dracontium*, dragon-plant.—*Hamantibus*, blood flower.—*Crinum*, Asphodel lily.—*Pancratium*, sea-daffodil, &c. all of which are perennials, sending up stalks annually, terminated at top by that kind of calix denominated a *spatha*, enclosing a *spadix* of flowers, and after obtaining a certain growth, the *spatha* or sheath bursts open, and protrudes the *spadix*, supporting sometimes but one or few flowers, and sometimes many. See **SPADIX**.

Most of these plants are nearly allied, in habit and structure, to the liliaceous tribe; distinguished however, from that tribe of plants by their *spatha* or scabbard, out of which the *spadix* of flowers is protruded; the liliaceous kinds having no *spatha*, nor any other calix whatever.

SPADIX.

The particular receptacle and pedicles of spadiceous or spathaceous flowers above described, being protruded out of that kind of calix called a *spatha*; and sustains from one to many flowers, as in *Narcissus*, &c. See **SPATHA**.

The *Spadix* was originally applied to palms only, but it is now extended to all receptacles and pedicles of flowers, whether single or aggregate, that have a *spatha* or sheath for their calix; which kind of calix being in form of a sheath or scabbard, bursts lengthways and protrudes the *Spadix*. See **SPATHA**.

SPARTIUM, Broom.

Consists of shrubby flexible plants, of the deciduous tribe, both hardy and tender, for diversifying the pleasure-ground, and greenhouse collections; all of upright moderate growth, with long rush-like shoots, thinly garnished with trifoliate, and single spear-shaped leaves, and numerous papilionaceous flowers.

Class and order, *Diadelphia Decandria*.

[*Characters*.] **CALIX** is monophyllous, tubulous, heart-shaped, with a short margin, having five small denticles.—**COROLLA**, is papilionaceous, with five petals, consisting of a large obcordated, wholly reflected vexillum, two oblong oval wings shorter than the standard,

standard, annexed to the filaments, and a dipetalous, oblong, hairy carina, inserted also in the stamina.—STAMINA, ten unequal, diadelphous filaments, with oblong antheræ.—PISTILLUM, an oblong hairy germen, awl-shaped, rising style, having an oblong hairy stigma.—PERICARPIUM, a long, cylindric, obtuse, bivalvous, unilocular pod, containing roundish seeds.

There are about ten species in this genus, all of shrubby growth; the first of which grows wild abundantly in England, &c. all the others are exotics, chiefly from Spain, Portugal, Italy, and other southern parts of Europe, and the Levant; about six or seven species are retained in our gardens for variety and ornament, in the shrubbery and green-house collection. Some of them being very hardy, others somewhat tender, requiring shelter of a green-house in severe winters.

Hardy Kinds.

About three or four species are hardier than the rest, and succeed in the open ground in all weathers the year round: the first of which is our common English Broom, and the others are originally from abroad, the countries above-mentioned.

¹SPARTIUM *Scoparium.*

Common Sweeping Besom Broom.] Rises with a shrubby flexible stem, and numerous, angular, smooth, green, flexible branches, five or six feet high; ternate and single leaves; and numerous bright-yellow flowers all along the sides of the young branches in May and June, succeeded by plenty of ripe seed in Autumn.

This plant grows wild in sterile grounds in England, and most parts of Europe, and not very commonly admitted into gardens, only in some extensive shrubberies, for the variety of its singular growth, and conspicuous bloom of flowers. In the country it being made into besoms, thence denominated Brooms; hence the name *Spartium Scoparium*, Sweeping Broom.

²SPARTIUM *Junceum.*

Rusby Spartium, or Common Yellow Spanish Broom.] Rises with a shrubby stem, and taper, opposite, flexible, rush like, green branches, eight or ten feet high; small lanceolate leaves; and the tops of the branches floriferous, being terminated by loose spikes of large yellow flowers, from July till September, succeeded by plenty of seeds in autumn.

Variety.] Double-flowered Spanish Broom; producing large full double-flowers, but no seed.

³SPARTIUM *Radiatum.*

Radiated, or Starry Italian Broom.] Grows two or three feet high, with numerous angular opposite branches all around, assuming a bushy growth; ternate, linear, close-fitting, opposite leaves, having the folioles spreading round the stalks in a radius; and clusters of yellow flowers at the ends of the branches, appearing in June and July.

Of the above three species, the two latter are the most commonly cultivated; having been long residents of our shrubberies: all three however, succeed any where, producing abundance of flowers and seed annually; and from the scattered, or self-sowed seeds, many young plants often rise without care, the following spring.

Tenderer Kinds.

The following sorts being rather of a more tender nature, especially while young, are often potted, and treated as green-house plants; yet they mostly stand our moderately sharp winters, tolerably in the full ground; it is however, proper to pot some for shelter in winter, and plant some in the full ground in a warm situation, to take their chance.

⁴SPARTIUM *Monospermum.*

Monospermous, or Single-seeded, White Spanish Broom.] Grows six or eight feet high, with numerous angular, rush-shaped, silvery branches; small spear-shaped leaves; and lateral clusters of white flowers at the sides of the branches, in July and August; succeeded by pods containing a single seed only.

Variety.] With yellow flowers.

This species being moderately hardy, is very commonly planted in the open shrubberies, as a hardy flowering shrub; it is however, proper to retain some also in pots, especially while young, to have occasional shelter from severe frost.

⁵SPARTIUM *Spinosum.*

Spinous Italian Maritime Broom, or Prickly Cytisus.] Grows five or six feet high, with angular slender branches, armed with spines; ternate, thinly-placed leaves, and clusters of bright-yellow flowers at the ends of the branches, in June and July.

⁶SPARTIUM *Scopius.*

Scopius, or Spreading Prickly Spanish Broom.] Hath spreading spinous branches, oval leaves,

and largish yellow flowers, in July and August.

⁷*SPARTIUM Angulatum.*

Angulated Eastern Broom.] Grows six or eight feet high, with numerous sexangular branches, garnished with single and ternate leaves; and the tops of the branches floriferous, being terminated by loose spikes of pale-yellow flowers, appearing in July.

All the above seven species of *Spartium*, rise with shrubby durable stems and branches; mostly of a flexible nature, the branches in particular being very slender and pliable, producing long rushy green shoots, generally, however, assuming an erect growth; the leaves generally small, and thinly placed, and the flowers moderately large and conspicuous, all of the papilionaceous or butterfly kind, with five petals, as in the *Characters*, and mostly of a strong agreeable odour; succeeded by long cylindrical leguminous seed-pods, ripening in autumn: though some of the foreign sorts do not always ripen plentifully in England, but are obtained in abundance from Spain, Portugal, and countries adjacent.

They all grow naturally in most of the southern parts of Europe; and the first sort, *Spartium Scoparium*, also in great abundance in this country, in barren uncultivated lands, often proving a most troublesome plant to extirpate in grounds intended for cultivation.

As to the merit of all these shrubs, in gardening they may be all employed as flowering shrubs, or furniture to embellish the shrubbery compartments; the Common Spanish Broom, Radiated, and Monospermous kinds, &c. particularly, are the most common sorts in the English gardens; and the *Spartium Scoparium* is also often thinly interspersed in extensive shrubberies, to encrease the variety: but all the species, both hardy and tenderer kinds, may be exhibited in the shrubbery plantations; being careful however, to station the tenderer sorts in the warmest situation, to take their chance of all weathers the year round, in common with the hardiest kinds.

It is, however, also proper to have some of the tenderer kinds always in pots, to be treated as green-house exotics, for the greater certainty of preserving the species, in case the others in the shrubbery should suffer by the severity of rigorous winters.

Most of these plants having long naked or thinly fibrated roots, often inclining to run down with a long tap-root, should generally be planted where they are finally to remain while young, as they do not succeed well, if removed when large and old.

They are raised in abundance in all the public nurseries for sale.

Method of Propagation, &c.

They are all propagated by seed in the full ground, sowed in the spring of the year; and the double-blossomed varieties, &c. by layers and cuttings.

Some of the sorts ripen plenty of seeds in this country, but that of all the sorts is procured in abundance by the nursery and seedsmen for sale; which should be sowed in the beginning of April, in four-foot-wide beds of common earth, either in drills near an inch deep, or bedded in that depth; they will soon germinate, and the plants rise freely in a short time, giving occasional watering, and weeding all summer; and in winter, it is eligible to hoop the beds of the tenderer sorts, in order to be matted in frosty weather; and in the spring following, it is advisable to prick out the whole in nursery-rows, it being proper to remove them out of the seed-beds, when but one year old, on account of their tap-root aforesaid, which should now be shortened; then plant them in rows two feet asunder, and one foot apart in each row; here to remain two or three years, then transplanted finally into the shrubbery; planting also some of the seedlings of the tenderer kinds, immediately from the seed bed into pots, and placed in the green house in winter.

Observe however, in raising the tenderer sorts, that, for the greater certainty of success, it will also be proper to sow some in pots, plunging them in the shade all summer; where the plants will come up freely, being careful to remove them under a garden-frame, or green-house in winter, to have shelter till spring, then pot the seedlings off separately as above, in order to be managed as hardy green-house plants; and in a year or two, having acquired strength, some of them may be turned out into the full ground.

By Layers and Cuttings.—The double blossomed Spanish Broom, and the other varieties, not continuing the same from seed, must be propagated by layers or cuttings, to preserve the sorts with certainty. Make the
layers

layers in autumn or spring, and plant the cuttings in spring or summer, some in the full ground, others in pots, and plunged in a hot-bed to forward their rooting.

SPATHA, a Sheath.

Being the common calix of the spadiceous flowers; and which, being in form of a sheath or scabbard, bursts open on one side, longitudinally, from bottom to top, and protrudes the *spadix*, a sort of receptacle and pedicles sustaining the flowers, consisting sometimes of but one, and sometimes of many florets.—See SPADICEUS *Flos*, and SPADIX.

Examples of the Spathaceous plants are *Narcissus*, *Amaryllis*, *Galanthus*, and *Crocus*, &c.—See SPADICEUS *Flos*.

The *Spatha* always terminates the main flower-stalk, is mostly of an oblong form, and sometimes globular, as in onion and leek, &c. closely inclosing the *spadix*, till the flower acquires maturity enough to burst it open, and consists either of one piece, as in the greater number of spathaceous plants; of two, as in some few sorts; or of a number of scales placed imbrication, as in the plantain-tree.

SPATHACEÆ *Planta*, (from *spatha*, a sheath).

Spathaceous plants, such whose flowers are protuded from a *spatha* or sheath. See SPATHA.

SPAWN, a progeny or off-spring.

In gardening, is often applied to such small off-sets, suckers, and sprouts that rise numerously from the roots, &c. of certain plants, serving for the purpose of propagation.

Therefore this small Spawn, or off spring of vegetables, may be considered as parts similar to the whole plant, as that being separated from the parent vegetable, and planted, they readily grow, and commence proper plants, and thereby renew or propagate their respective species with great facility and abundance.

But Spawn among gardeners, in the general acceptation, is more peculiarly applied to the progeny of mushrooms, being an off-spring from the root of those *fungi*, consisting of minute white parts, shooting and running in the earth or dung, like small white, thready fibres, assuming the appearance of long white strings, productive of numerous minute white knobs, appearing at first the size of small pin-heads, the whole

smelling strong of the mushroom; and those little knobs being infant plants, they gradually increase in volume to proper mushrooms, which are quick of growth, and of very short duration; but the same Spawn running in the earth, &c. furnishes a plentiful supply of mushrooms from the bottom in regular succession, for a considerable time, sometimes for several months.

So that mushrooms propagate in great abundance by this Spawn detached from the root; and is the only method of propagation yet discovered, for raising them by the progress of horticulture; for the lumps of spawnny earth or dung being planted in a sort of hot-bed of horse-dung, the spawn soon vegetates, and increases considerably, furnishing mushrooms in a short time fit to gather; these hot-beds in which we deposit the mushroom, being always made with new horse-dung from the stables, previously fermented in a heap, to evaporate the first violent heat, then formed in a long narrow ridge five feet-wide and four high, like the roof of an house to shoot off the wet; and having remained open, and exposed to the weather two or three weeks, till the great heat abates, the lumps of Spawn are planted all over every part of the bed at little distances, just within the surface; and the bed is then earthed all over an inch or two thick, and closely covered a foot thick, with dry litter; thus the moderate heat and peculiar quality of the dung, sets the Spawn a-working, so as often to produce plenty of mushrooms in six or eight weeks: and the same bed frequently continues furnishing a supply five or six months, or longer; but new beds must be made every year or oftner; and the old ones pulled to pieces, saving all the good fresh Spawn thereof, for spawning future beds.—See AGARICUS *Campestris* in the *Addenda*.

Thus, through the effects of the peculiar warmth and quality of horse stable-dung, the litter, and plenty of the short stuff together, formed into a hot-bed as above, the mushroom Spawn encreases, furnishing both mushrooms, and a plentiful supply of young Spawn for future beds: likewise any common horse-dung hot-beds, horse-dunghills, &c. moderately rotted, is often productive of a great deal of good mushroom Spawn naturally; probably from some fine spawnny matter, or the mushroom seed having accidentally

cidentally mixed in the dung or earth, &c. And thus the Spawn produced by either of these effects, is the only certain resource yet known for propagating that species by art, no seed having as yet been sufficiently discovered, by which we can raise this plant; but the Spawn from the root, being as it were living foetuses or infant plants, which renew their species as certainly as seed.

However, besides this Spawn or off-spring of the root, the naturalists are agreed that mushrooms have also generative organs, and produce flowers and seed like other plants, and naturally propagate themselves also by seed, as well as by the Spawn; but from the exceeding minuteness both of the genital organs and seed, and their great obscurity, or concealed situation, they yet remain invisible; though it is supposed they are contained in the *lamellæ* or gills of the mushroom, and which, when full-grown, discharges the seed upon the adjacent ground, and thence probably some is disseminated by the winds, &c. to other distant soils and situations adapted to their growth; and penetrating into the earth, grow and become mushrooms, the roots of which multiply and furnish proper Spawn also for the work of propagation.

But it was long the opinion of many, that mushrooms never possessed the power of propagation at all, but supposed to owe their existence to the putrefaction of earth, dung, &c. which doctrine, however, the modern botanists have sufficiently refuted.

For mushrooms being proper plants, they, either by Spawn or seed, or both, propagate themselves like other vegetables; and it is probably from the dissemination of the seed, by some mysterious progress of nature, to peculiar soils and situations, that we often find both mushroom Spawn, and mushrooms growing in obscure places, where none ever grew before.

By Spawn, however, in particular, it is obvious that mushrooms propagate themselves plentifully, and by which, with proper garden culture, we can raise abundance of mushrooms at pleasure.

Therefore the mushroom cultivators always furnish themselves with a sufficient quantity of fresh Spawn every year, for every new bed, procuring it all times of the year, but more plentifully towards the end of summer, and in autumn, from the places of its growth, such as old mushroom-beds; any

old horse-dung hot-beds, and horse-dung-hills, that lay moderately dry, and remained undisturbed at least half a year, or a year or two; also sometimes in old compost heaps, consisting chiefly of horse-dung; in all of which the spawnny substance discovers itself in dry lumps of dung and earth, which lumps should be taken up entire, as hereafter noticed; likewise in stable-yards, in bye dry corners, where any quantity of horse-dung has lain dry and undisturbed any considerable time, lumps of Spawn are often obtained. It is also found in fine perfection, in the horse-rides belonging to great livery stables and horse-dealers in and about London, &c. which rides being under cover to shelter them from wet, and the ground spread thick with the short dung from the stables for the horses to tread on, being generally permitted to remain some considerable time without cleaning out, and being always dry, upon examining towards the sides next the wall, is frequently found most excellent mushroom. Spawn in large cakes; likewise in horse-mill tracks, where horses are constantly employed in working the mill, and they dunging, &c. in the tracks, it being occasionally swept up towards the sides, and the bottom sometimes permitted to lie some considerable thickness a long time, upon turning it up, are frequently found fine lumps of excellent strong Spawn: also in kitchen gardens, where any piece of ground having been well dunged in the spring, with new or but moderately-rotted stable-dung, or old dry hot-bed dung, &c. probably having embryo Spawn already formed therein, and which dungs happening to be but slightly digged in, or covered but a moderate depth with earth, sometimes is productive of clusters of mushrooms in patches, towards autumn in dry seasons, and in which places we often find lumps of very good Spawn: remarking, that in all the above places the Spawn is met with occasionally at all times of the year, but more certain and plentiful towards the end of summer, and in autumn, before perished by the wet and cold in winter; being found in dry lumps, and cakes of dung and earth, appearing, as before said, white and stringy, smelling strong of the mushroom.

I have sometimes had mushroom Spawn produced naturally all over the surface of an old cucumber, or melon hot bed in autumn, and

and having continued the frame and lights constantly over it all winter long, covering the surface of the mould thickly with dry hay in frosty weather, laying also dry litter round the outside of the bed, have, towards spring, had a full crop of very fine mushrooms: in one bed in particular, in which was a fine loamy earth, they were remarkably numerous, large, thick of flesh, and of firm texture; and after this produce, gathered a fine parcel of Spawn.

But mushroom Spawn is also obtained in rich pasture-grounds towards the end of summer, and in autumn, before the rain and cold commences; the months of August and September being generally the proper season when the mushrooms rise naturally, serving as a direction to the place to find the Spawn; then carefully opening the ground, the Spawn will appear in the earth as above, which may be dug up in lumps, and carried home in baskets for use; this field Spawn however, cannot always be so readily obtained in any considerable quantity; and as it is found only in pasture-grounds, it may be very inconvenient to break up, and spoil the sward in search of it; besides, many poisonous sorts of *fungi* grow in the fields, also from Spawn; we ought to be cautious when we are gathering Spawn for mushroom beds.

From the above hints of the places of growth of mushroom Spawn, we may readily know where to obtain it in sufficient quantity for the purpose of spawning mushroom-beds.

But after all, garden or bed Spawn produced in any horse-dung beds, heaps or lays of horse-dung, &c. before-mentioned, is preferable to the field Spawn for garden culture, it generally producing much thicker, more fleshy, and firmer mushrooms, of a richer flavour.

Therefore, in demolishing old mushroom-beds, it is incumbent on us to preserve all the lumps of young fresh Spawn, also all such we occasionally meet with in any old dung hot-beds, dunghills, &c. laying the lumps up in the dry till wanted; rejecting however, any very old worn-out Spawn, as far as it can be distinguished; and the virgin Spawn, or such that has not been worked, generally yields the finest mushrooms; for sometimes, even the young off-spring Spawn, or such that have been long worked from

bed to bed, is apt to degenerate, there being often a very material difference in the goodness of Spawn; that which is fresh and full of heart, will often produce abundance of fine mushrooms for several months in the same bed; but such that is worn-out or degenerated, send up only a flash of trifling little heads at first, of no substance, and probably never produce any more to signify.

There is also a fruitful, and barren sort of mushroom Spawn; the former is distinguished by the substance of the fibry or stringy white shoots, &c. and mushroom-like smell, as before observed; but in the base sort, the thready fibres are considerably more abundant, fine, and downy, often appearing like a fine white down, and being of no substance, produce only a flash of small white *fungi* destitute of the fleshy part, and which by the mushroom-men is commonly called white-cap; and by not perfectly distinguishing it, many have been disappointed in their crop.

It is observable that horse or stable-dung, of all others is the most remarkable for promoting mushroom Spawn, even often alone in the dung-heap, without any addition of earth, though having a small portion of any earthy substance, it may probably have the greater effect; for new horse-dung consisting of the wet litter, and the short stuff together from the stables, but the more short the better, and being collected in any considerable quantity, either in any common cucumber or melon hot-beds, or remaining in the dung-heap a considerable time, it often becomes of a certain agreeable temperament, peculiar to the growth of mushrooms, especially if it does not burn much by the first violent heat; and that after remaining from winter or spring, until autumn or spring following, or longer, it frequently furnishes lumps of excellent Spawn.

Methods are sometimes practised to obtain Spawn more abundantly by art, by the effects of horse-dung, both in hot-beds and in compost heaps; sometimes in the former case, by planting small pieces of Spawn, or spawny earth along the top edge of the later cucumber hot beds in summer, or in the sides of any horse-dung heaps, having a little warmth remaining; so that the moderate heat of the dung in the bed or heap, sets the
Spawn

Spawn a-running, as sometimes both to produce a few mushrooms in autumn, and encrease considerably for future use in spawning proper mushroom beds. And in the second case, it is performed by a compost of dung and loamy earth together; procuring in spring, or early in summer, a quantity of fresh horse-dung, consisting of plenty of short stuff, and a due proportion of long together; and casting it together to ferment a fortnight or a month, that the rank burning vapour may pass away; then having some loamy earth, or other good substantial mould, or any spawny soil from old beds, form the dung into a long narrow ridge, mixing some of the earth occasionally towards the outside, and in a fortnight or three weeks, the heat becoming quite moderate, cover the whole with a dry long litter to defend it from the wet, permitting the whole to remain some considerable time; and thus probably some generating substance of mushrooms, either Spawn, or seed, or both, having by some means previously, and accidentally introduced itself in the compost, which by its certain warmth and quality promotes its vegetation, and encrease, as sometimes in three or four months to furnish a good quantity of eligible Spawn.

Observe, in collecting the mushroom Spawn found occasionally in all the aforementioned places of growth, the lumps of dung and earth, in which it appears should be taken up as entire as possible in a basket, and carried into some dry shed or other apartment, there deposited till wanted; previously observing, that if the lumps of Spawn are any ways wet or very moist, they must be spread on the floor thinly a week, or fortnight, or more, till thoroughly dry: then may either plant it if the bed is ready, or lay it up close in some dry corner of the apartment, or put it up in hampers; covering the whole thickly with dry litter or garden-mats: and here it may remain till wanted, for the purpose of spawning mushroom-beds; as it will retain its vegetating property several months: and the drier it is kept in moderation, the better it will improve in its vegetable faculty, and take more freely with the bed when planted.

About London good mushroom Spawn is a valuable article among the kitchen gardeners, who raise great quantities of mushrooms for the markets; and in consequence thereof, some of their labourers make it their

business, at certain times of the year, but more particularly in summer and autumn, to go about to different places collecting it, which generally pays them well for their trouble, as they find a ready sale for it, from five or six to ten shillings per bushel.

Whosoever may have occasion to purchase Spawn from the environs of London, will meet with it most readily in the Neat-house gardens near Chelsea; also in the neighbourhood of Lambeth, Battersea, Hammer-smith, &c. also in Covent-Garden market.

It may be packed up in hampers, and sent to any distance, either by land or water-carriage.

SPICA, a Spike.

A mode of inflorescence, or manner of flowering peculiar to many plants; consisting of a simple peduncle or flower-stalk, supporting many flowers all along its sides, without any pedicle or partial foot stalk, but are sessile, or set close to the main stalk, generally in alternate arrangement.

But the florets of a Spike are also sometimes single rowed, and sometimes double-rowed, &c.—When single rowed (*Spica secunda*) the flowers are all turned towards one side; and double-rowed (*Spica disticha*) when they stand two ways.

SPINA, a Spine or Thorn.

One of the armature of plants, and are protruded immediately from the wood, being an expansion of the ligneous body; by some compared to the horns of animals, which adhere to the bones of the skull, so that the Spine or Thorn differ from the prickle, *aculeus*, which are detached only from the bark, and not so strong and hard as Spines. See ACULEUS.

Spines are intended by nature as armour to certain plants, to keep off cattle and other animals that would injure them.

Thorns arise either upon the stem and branches, as in buckthorn, box-thorn, white-thorn, sloe, wild-plum, pear, orange, triple-thorned acacia, false-acacia, furze, and many others of the tree and shrub-kind; or on the leaves, as in holly, American aloe, acanthus, thistle, Adam's-needle, juniper, butcher's-broom, &c. On the calix, as in thistle, centaury and mud-apple; or on the seed-vessel and fruit, as in thorn-apple, prickly spinach, &c.

Spines rise either singly, as in most spinous plants; doubly or by pairs, as in many sorts; and triple, as in the three-horned acacia.

By

By culture many plants lose their Spines, as plum, pear, medlar, orange, citron, &c. and the leaves of holly by age.

SPINACIA, Spinach.

Spinach is a noted culinary herb of the annual tribe; valuable as an esculent for its large leaves for various culinary purposes most times of the year; having broad triangular and roundish leaves, rising in clusters close to the ground; succeeded by upright tall stems, supporting spikes and clusters of small apetalous male and female flowers on separate plants.

Class and order, *Dioecia Pentandria*.

Characters.] CALIX, dioecious flowers, having in the males a calix, cut into five oblong, obtuse, concave segments; and in the females is monophyllous and permanent, cut into four acute parts, two of them being very small.—COROLLA, no petals.—STAMINA, five capillary filaments, with oblong didymous antheræ.—PISTILLUM, in the females a roundish compressed germen, and four hair-like styles with simple stigmas. PERICARPIUM, no seed-vessel; the seed is roundish, and lodged in the permanent calix, and is either thorny or smooth in the different varieties.

There are but two species in this genus, one of which only is cultivated, being the common culinary Spinach, comprehending two eminent varieties; namely,—triangular leaved, with prickly seed,—round-leaved, with smooth seed: the former being the hardiest, is more valued for the winter crop; but the latter having larger, thicker, and more succulent leaves, is preferable for spring and summer.

The species is,

SPINACIA *Oleracea*.

Oleraceous, or Common Culinary Spinach.] Hath a somewhat spindly fibrous-root, crowned with a tuft of large, broad, triangular, and roundish leaves on foot-stalks, close to the ground; and when it shoots for seed, rises with upright, hollow branchy stalks three feet high, producing spikes, and clusters of numerous small, apetalous, greenish flowers, male and female, on separate plants; succeeded in the females by roundish close-fitting seeds, in some armed with spines, in others smooth.

Remarking, the male plants generally produce their flowers in spikes, and the females in close clusters at every joint.

Varieties.] There are two remarkable varieties of this species, each of which was formerly considered as a distinct species; but the improved Linnæan system makes them varieties of one and the same species, their specific determination being in the close-fitting seeds, *fructibus sessilibus*, which is exactly the same in both varieties; there is however, a pretty permanent distinction in their leaves and seed; one variety having triangular arrow-pointed leaves, and prickly seed; the other having roundish leaves and smooth seed, as below.

Triangular Spinach with Prickly Seed.] Hath large triangular arrow-pointed leaves, five or six inches long or more, being broad and angular each way at the base, running up to a narrow point at top; and the seeds are mostly armed more or less with short spines.

Round Spinach with Smooth Seed.] Hath large roundish or oval leaves, five or six inches broad or more, of a more thick, fleshy, succulent consistence; and the seeds more round, mostly free from spines, and quite smooth.

Both these varieties admit of some variations in the shape and size of the leaves; the broadest and thickest leaved sorts are consequently superior in goodness; remarking of the Round Spinach in particular, some will have roundish leaves, others oval or oblong, and one sort exhibits itself with much rounder, broader, and thicker leaves than the others, generally of a more stocky and luxuriant growth, and stronger green colour, and is the most valuable variety of the round-leaved kind: but observing both of the triangular and round-leaved varieties, we should endeavour as much as possible, to mark the most stocky and broad-leaved plants to run up for seed, in order to obtain and continue the proper breed of such eligible varieties only, sufficiently for general culture.

As to the merit of each variety;—the triangular Spinach being of a more hardy nature, is generally cultivated for the main winter crops; and the round-leaved sort claims precedence for the size and thick consistence of its leaves, but being not quite so hardy as the other, it is cultivated principally for the spring and summer crops.

Both the varieties are herbaceous annuals, that succeed in the open ground, requiring to be raised annually from seed sowed in an

open situation, in spring, summer, and autumn, to remain when sowed; and the plants coming up in a fortnight, they attain perfection for use in two or three months, then run up to stalk, producing flowers and seed, and totally decay, root and all, the same year; though if sowed in autumn, they come up and stand the winter till next spring, but not longer than April or May, before they run to seed, and perish as soon as it is ripe.

They commonly flower in June, and when in flower, the male and female plants are then distinguishable, the former generally producing the flowers in spikes, having the flowers furnished with the stamina, sustaining a yellow farina, being the male dust for the impregnation of the flowers of the female plants, which have no stamina, only the female organs, the germen and styles, on which the male plants naturally discharge their farina, and soon after decay; but the female plants continuing their growth, and being thus fecundated, the embryo seeds grow fast to perfection, being also thereby fertilized or rendered prolific, as that when sowed they will readily grow, for without the vicinity of the male-flowers, many of the females would prove abortive, and all the seeds sterile, which determines how necessary it is in Spinach, and other dioecious plants, to leave a sufficiency of the males to impregnate the females.

Spinach is obtained for use almost the year round by different sowings, from January till August or September; at about a month's interval between the early sowings, two or three weeks in the main spring crops, and not more than a fortnight in summer; for the plants of each crop of the spring and summer sowings will not continue longer for use, before they will fly up to seed; but the autumn sowings, performed from about the middle or latter end of July, to the middle or end of August, do not run so soon, more especially those sowed in August, which is the only proper season for sowing the winter crops, and which coming in for use in October, continue all winter and spring, until May, then shoot up to seed; being succeeded abundantly by the spring-sowed crops, as above.

As to the culture of Spinach it is very easy: both the varieties may be raised in any situation from seed, sowed either broad-cast

and raked in, or in drills; the plants remaining where raised, require only a little thinning and clearing from weeds; however, there being several material hints necessary to be generally known, in order to obtain Spinach in full perfection in the different seasons of the year, we will therefore treat of its culture pretty fully; first exhibiting hints for its general culture, afterwards the culture of each variety, separately in the different seasons.

Hints of its Propagation and General Culture.

The propagation of Spinach is effected only by seed, as being an annual, sowing it every year in spring and autumn; the former season of sowing furnishing the main-spring and summer-crops; and the autumn sowings in August furnishes Spinach all winter, and for early spring use, until May.

It may be sowed at several intervals of time, from January till August, as every month, three weeks, and fortnight, according to the earliness or advanced period of the season, so as to obtain a regular succession of Spinach most part of the year; the spring and summer sowings attaining perfection for use from April till August or September, and run to seed, and totally perish the same year; but the autumn sowings in August being designed not to come in for use till October, in order that it may remain all winter, and the following spring, until succeeded by the spring-sowed crops, as before remarked.

Observe of the spring sowings, that as the very early sowings in January run soon to seed, should sow but a moderate quantity; but may sow freely in February, March, and April, every three weeks, for the main-spring crops, which will supply plenty of young Spinach in great perfection, from April or May, till towards midsummer.

But if Spinach is required throughout the summer, continue the sowings every fortnight, all May, June, and July; though the summer-sowed Spinach rarely attains full perfection, like the spring sowings, as it runs hastily up to seed; but should sow frequent, and but little at a time.

And as to the autumn sowings, as the plants do not run the same year, should always sow a good full crop to stand for winter, and early spring use, as aforesaid.

With

With respect to the soil and situation for the culture of Spinach, it succeeds in any common soil of a kitchen-garden, but the richer in dung the better; for a well enriched soil makes great difference in the growth of Spinach, by exhibiting the plants of a luxuriant growth, in respect to size and thick consistence of the leaves, a material excellence to be regarded in Spinach; always chusing an open situation, not too near low-spreading trees, &c. for Spinach never succeeds in close or shady places, in which it always draws up weak, and soon runs to seed, without attaining perfection; but having a free exposure open to the sun and air, encourages a stocky growth, and large expansion of its leaves. A warm border may be proper for the early crops, but for the main crops in general, the open quarters is the most eligible; though a broad warm-lying border may also be proper for some part of the later sowed winter-crops occasionally, for the sake of having the advantage of a little shelter of the fence, and benefit of the sun during the winter season.

Let fresh seed not more than a year old be procured for each sowing, for this will be found of much importance in the free growth of the plants; and for the autumn sowings of the winter crops, it is of advantage to procure new seed of the same year's sowing, if possible.

The ground being digged, the seed may either be sowed broad-cast and raked in, or in shallow drills a-foot asunder; though broad-cast is the most expeditious, and probably the most eligible method for the growth of the crop; sowing it all over the surface moderately thin, either in one continued plat, and trodden down evenly, if light ground, and raked or harrowed-in with a large rake, or light harrow; or may divide the ground into four or five-feet-wide beds, with foot-wide alleys between; more especially for the early and winter crops in wet ground, and the seeds being sowed as above, rake them in evenly: but drill-sowing may also be occasionally practised, drawing the drills with an hoe flatways, near an inch deep, and ten or twelve inches asunder, scattering the seeds thinly along the drills, and rake the earth over, full half an inch deep, which mode of sowing Spinach may be more particularly eligible, when obliged to sow between other crops; it also more

readily admits of hoeing up the weeds between the rows; and if sowed thin, and the plants also thinned proportionably, they will grow as large and fine as in the other method of sowing, and the produce very conveniently gathered; so that drill-sowing of Spinach, the spring-crops particularly, may also be effected occasionally, between other crops already growing in rows; as beans, cabbage, cauliflowers, &c. and may likewise be sowed in wide drills alone; i. e. the rows a yard asunder, to admit of intercropping in the intervals with rows of cabbages, beans, and other things occasionally: however, the broad-cast sowing being the most ready and expeditious, and generally also the most advantageous for making the most of the ground when necessary, is the most commonly adopted method of sowing Spinach, for large tracts of ground especially. See SOWING of SEEDS.

Observe, in either of these methods of sowing Spinach, to scatter the seeds moderately thin, as the plants at any rate require to be thinned to three or four inches distance at least; do not however spare seed in a moderate way, and let it be directly raked or harrowed in, previously observing of that sowed broad-cast all over the surface, if in light loose land particularly, it may be proper first to tread the seed evenly down, then rake it effectually with a large rake; and of that sowed in drills, rake the earth evenly over it the depth aforesaid, and rake the surface smooth.

These seeds quickly germinate, and the plants will come up in a fortnight, or perhaps, if sowed very early in spring, it will be three weeks or a month before they come up.

Observing however, in respect to their culture, that when the plants have three or four leaves an inch broad, they should be thinned and cleared from weeds, performed either by hoe or hand, but the former is the most eligible; chusing dry weather, and cut out the plants to three or four inches distance, together with all the weeds in every part; the above distance however, is scarcely sufficient, unless intended to begin thinning out the plants for use while young, otherwise it is adviseable to hoe them out six or eight inches asunder; especially the spring and summer crops of the round Spinach, which having proper room, will grow very

large, and spread its broad leaves widely around, and will not run to seed so soon as if left close; for the spring and summer-sowed Spinach in particular, if left too close, draw up weak and trifling, and soon go to seed: but as to the winter crops of triangular or prickly Spinach, if thinned finally to four or five inches distance will be sufficient. See their *Spring, Summer, and Winter Culture*, under separate heads.

Spinach is often sowed with other crops, for the sake of cropping the ground to the best advantage when necessary; for a full crop of Spinach requires a large space of ground, so as to furnish any sufficient quantity at each gathering; yet as being plants of low growth, and a temporary crop soon acquiring perfection, and each crop soon cleared off the ground for use, most of the London kitchen-gardeners and many others, who find it their interest in having as many crops from every spot of ground as possible, generally, to save ground, contrive to sow the main spring-crops of Spinach mostly with such other crops as admit of its growth without retarding or injuring one another, and grow to perfection in successive order, out of one another's way; such as with radishes and lettuce; and between rows of cabbages, cauliflowers, beans, and some other esculents in wide rows, mixing nearly an equal quantity of the spinach and radishes, and only a small sprinkling of coss-lettuce; sowing the whole together broad-cast, and rake them in; the radishes take the start of the others, arriving to perfection before the Spinach, being then daily thinned out for use; and the lettuces are transplanted while young into another place, leaving the ground at last occupied only by the Spinach; unless the ground was also cropped with cabbages and cauliflowers, as is often practised.

For it is also customary among the kitchen-gardeners, in order to make the most of the ground, to sow the main crops of spring Spinach and radishes, in February, March, and April, in the open quarters, where the general crops of cabbage and cauliflowers are intended; generally sowing the Spinach and radishes first by broad-cast all over the ground, and rake or harrow them in; then either directly, or in a week, fortnight, or a month after, as it suits, plant the cabbages and cauliflowers in rows at

proper distances, as directed under their proper heads. See BRASSICA. They will soon take root, and get the start of the Spinach and radishes, without retarding their growth; and the two latter will be all gathered off for use, by the end of May, and beginning and middle of June; when the ground is hoed to cut up weeds, loosen the soil, and draw up earth to the stems of the cauliflowers and cabbage-plants.

But the above methods of sowing Spinach with other crops, is only recommended for occasional practice in the aforementioned cases; for in gardens where they are not necessitated to make the greatest advantage of the ground, it may be more adviseable to sow the main crops mostly alone, without the incumbrance of other crops; in which the Spinach will most likely attain the greater perfection: in this however, every one will suit his own convenience.

When the plants have leaves two or three inches broad, may begin thinning out some for use.

As to the method of gathering Spinach for use, it may either be cut up with a knife wholly to the bottom, if it wants thinning; or only crop the large outer-leaves, the root and heart remaining, shoots out again.

In gathering the spring crops however, we may at first, if the plants want thinning, cut them up wholly to the root, thinning them out where thickest in a gradual manner, so as to leave the standing plants at last full six or eight inches distant to grow to perfection, which, when beginning to shoot for seed, may also be cut up wholly to the bottom.

And in gathering the winter crop of Spinach, if the plants stand too close at first, some may be thinned out quite to the bottom; afterwards must only crop the larger outer leaves all winter, and early part of the spring; but when the spring is more advanced, and the plants grown large and require thinning, or when they begin to run to seed, may cut them up clean to the bottom.

Having thus exhibited hints for the general culture of Spinach, we now proceed to treat of the culture of each variety separately, in its proper season; first, the spring and summer crops; second, the winter crop.

Spring and Summer Crops.

The round or smooth Spinach being the most eligible sort for the spring and summer culture,

culture, for the reasons before observed, February, March, and April is the principal months for spring-sowing the main crops thereof; though to obtain a succession of this spinach as early and late as possible, several sowings may be performed, from January till August, as already observed.

The first sowings may be performed in the beginning, or any time of January, if the weather is open; or, for the greater chance of success, may sow twice in that month if the weather permits, in a warm dry situation; sowing only a moderate portion at this early season, especially in the beginning of the month, as it may be cut off by inclement weather; or if it survives the frost, the plants are apt to go to seed before they acquire their proper growth.

In February however, for the main spring crops, may sow more freely in almost any open situation, especially towards the middle of the month; it will however, be proper to sow also twice in this month, at two or three weeks interval, which will ensure the greater success of plenty in a regular succession a long time, to succeed the winter crops, which will run to seed in April and May, about the time these sowings arrive to the first state of maturity for the table.

In March and April, it is also adviseable to continue sowing the same sort of Spinach every three weeks, in an open situation, which will furnish a regular supply for the table or market in May and June.

And in the months of May, June, and July, if a constant succession is required all summer, it is proper to repeat the sowings almost every fortnight during those months, for these plants very soon shoot up for seed at this season: chusing for these summer-crops the strongest moist soil the garden affords in a free situation, and if you can have the opportunity of moist weather for sowing, it will be a particular advantage; being careful to sow the seed rather thinner than common: and the plants should also be hoed out thinner in proportion, otherwise will soon draw one another up into stalk for seed. Observing, that if a regular succession is required to be extended also quite through the autumn, we must continue the summer sowings till the middle or latter end of July; and thus we procure a constant succession till the beginning of winter, or till succeeded by the winter crops in October.

With respect to the method of sowing all the above spring and summer crops of Spinach, it may be principally by broad-cast and raked in, or occasionally in drills, as before observed in the *General Culture*.

We already observed some mix radish seed with the Spinach, in sowing the main spring-crop, for the sake of cropping the ground more advantageously; also sowing it occasionally on the ground intended for cabbage and cauliflowers, in all of which every one may suit his own inclination and convenience, agreeable to the hints before given.

As to the culture of these spring and summer crops of Spinach, it is nearly the same as observed in the general culture; that when the plants have three or four leaves an inch broad, hoeing them out in dry weather to about three or four inches distance, cutting up all weeds; and when they are advanced in growth, so as nearly to meet, they will be fit for the table: when they may be thinned out regularly, the largest for use, cutting them up close within the ground; repeating the thinnings according as they are wanted for the family or market, and those remaining at last having full scope, will attain great perfection.

After however, all these spring and summer crops attain perfection for use, they soon shoot up stalks for seed, and become useless; which renders a repetition of several sowings necessary.

Some of the best plants of the February and March sowed crops should be left to run up, and produce seed for next year's sowing. See *Saving the Seed*.

Winter Crop.

Winter Spinach is the triangular or prickly sort, as being the hardiest, sowed in the end of July or beginning of August, and arriving to perfection for use the same year, in the latter end of September, or in October; and stands without running all winter, supplying the table all that season, and the following spring; being however, generally in good perfection all October, November, and December if mild weather, and often in moderate seasons continues growing all winter long; is liable however to suffer by severe frost; but the root and heart remaining sound, it recovers strength apace as the spring advances, and shoots out into large leaves

leaves abundantly till May, then it shoots for seed, being succeeded by the spring-sowed crop.

It is therefore adviseable to chuse principally the triangular or prickly Spinach for this crop, as being the hardiest to endure the frost and wet in winter.

The proper season for sowing this crop, is principally the first and second week in August, for if sowed sooner, it will get too forward, and be apt to run to seed the same autumn, or very early in the spring; however in cold or poor soils, in very exposed situations, it is proper to sow early in the first week of this month, as the forwarding the sowings a few days in such soils and situations is of importance, that the crop may get properly forward and obtain sufficient strength before the approach of winter. But in good rich warm-lying ground, if the sowing is performed any time in the first fortnight of the month, it may be time enough; and in some of the rich grounds about London, they often sow this crop of Spinach in the middle or latter end of this month, especially for the later crop; however, it is most adviseable to sow the main winter crops rather early in August, which generally proves a very successful season in most situations for sowing winter Spinach; observing, if showery weather happen about this time, it will prove an advantageous opportunity for sowing, as if sowed in dry hot weather this seed is apt to rise rather sparingly and straggling: do not however omit the proper sowing season as above.

Chuse generally for this crop an open situation, that lies tolerably dry in winter, and that enjoys the winter's sun.

And the ground being properly digged, immediately sow the seed while the surface is fresh and moist, sowing it generally by broad-cast all over the surface, either in one continued plat to make the most of the ground, or in four or five-feet-wide beds, for the convenience of standing in the alleys to do the necessary culture and gather the produce; and may scatter a sprinkling of brown, Dutch, and common cabbage lettuce, &c. along with the Spinach seed, to take their chance for culling out in winter and spring: directly, as soon as sowed, tread and rake it in evenly. Or the Spinach may be sowed in drills, either at a foot distance for a close crop, or three feet and a half asunder,

to allow of cropping between, in autumn with cabbages, or in winter or spring with beans, &c. But it is the custom with most of the London gardeners, to plant early cabbages in most of their winter Spinach ground, more particularly that sowed in the broad-cast way in one continued plat, or that sowed in wide-placed drills, planting the cabbage-plants generally in October, in rows three feet and a half asunder at least, they will continue their growth without impediment to the Spinach, which in spring being all cleared off for use, there remains a full crop of cabbages, &c. in good forwardness; so we thus both gain time and ground.

But with respect to the culture of this crop of winter Spinach, the plants coming up in a week or fortnight after sowing, will in three or four weeks after that, when their leaves are an inch broad, want thinning and clearing from weeds, performing it if possible by hoeing in dry weather, leaving the plants three or four inches asunder, which will be room enough for the present, as some may afterwards be gradually thinned out for use, so as to leave them finally about four or five inches apart; afterwards, must only crop the leaves for use all winter, taking always the larger outer ones, and the smaller leaves in the center gradually expand themselves in their turn for use in regular succession all winter and spring; but in the spring, when the plants grow large and crowd one another, or begin to shoot for seed, they may be cut up clean to the root.

Particular attention is required to keep this crop clear from weeds by occasional hoeings and hand-weeding as may be convenient, being particularly careful to clear away chickweed, which is apt to infest this crop greatly in winter; always shaking the largest of the weeds entirely off the ground, which if left at this moist season, would soon strike root again and grow.

Towards spring, after the rigours of winter are past, take opportunity of a fine dry mild day, and lightly hoe the surface of the ground about the Spinach, which will greatly recruit the vigour of the plants, and in February and March will shoot out strong, and attain fine perfection again for use: still cropping only the largest outer leaves at first, unless they stand too thick, or when they begin to shoot for seed, as before hinted, then may be cut up by the root, as they are wanted,

wanted, leaving a portion to produce seed as below.

Saving the Seed.

When intended to save Spinach seed, may allot a portion both of the spring and winter crops to stand and run up for that purpose.

Remarking, you may either sow a quantity of both varieties on purpose, in spring and autumn, in an open situation to stand for seed; or may leave a parcel of some of the crops that were raised for use; observing of the spring-crops, chuse principally that of the February or beginning of March sowing, which will run up early, and ripen seed the beginning of autumn following: and as to the winter crops, they being not raised till August, do not shoot till the following spring; though as they run earlier to stalk than the spring-sowed plants, they probably will ripen their seeds somewhat earlier in autumn.

Note, in the plants designed for seed, it may be of some advantage to have the two varieties, round and triangular Spinach, at some distance from another, lest by the intercommunication of the farina it may cause a degeneracy.

Observe likewise, in the plants allotted for seed, should draw out all the bad sorts, preferring those of the most stocky growth, with the largest, most expanded, and thickest leaves; thinning the whole eight or ten inches distance, and cut up all weeds.

They will begin to run up to seed-stalks in April and May: the winter crops generally shoot first, and are soon followed by the spring crops, flowering in June; at which time the male and female plants discover themselves distinctly; leaving however the whole to nature, the males will sufficiently fecundate the flowers of the female plants, so as the latter will be loaded with abundance of ripe fertile seeds, in the end of July or beginning of August.

When the seed is full ripe, which is obvious by its changing brown and hardening, the stalks must be pulled up, and spread to dry a few days, turning them occasionally to dry, and harden all the seed properly: then thresh them out, and bag them for use.

This newly saved seed is excellent to sow for the winter crop, provided it is ripe time enough; it however remains perfectly good for next year's sowing, but is not to be trusted to if more than a year old.

SPIRÆA, *Spiræa frutex*, &c.

This genus is composed of shrubby and herbaceous plants, consisting of many beautiful, deciduous, flowering shrubs, and floriferous herbaceous perennials, all of hardy temperament; and eminent for decorating the pleasure-ground, being of upright growth, adorned with spear-shaped, pinnated, trifoliate, and decomposed leaves in the different species, and terminated by spikes and clusters of pentapetalous flowers.

Class and order. *Icosandria Pentagynia*.

Characters.] **CALIX**, is monophyllous, acutely quinque-dentate, and permanent.—**COROLLA**, five oblong roundish petals inserted into the calix.—**STAMINA**, twenty or more slender filaments, having roundish antheræ.—**PISTILLUM**, five or more germens, supporting five styles, having capitated stigmas.—**PERICARPIUM**, oblong, acuminate, compressed, bivalvular capsules, containing a few small acuminate seeds.

There are eleven species of *Spiræa*, seven of them being shrubby, with durable stems, &c. and the other four are herbaceous, having durable roots, but mostly annual in stalk. All the shrubby kinds are originally exotics, from different parts of the continent of Europe and North America; and of the herbaceous kinds, some are indigenous plants of England, others exotics; but all the sorts, both shrubby and herbaceous, are very hardy, and most of them have been long inhabitants in our gardens for ornamenting the shrubbery, &c.

Shrubby Kinds.

Under this head is exhibited some very eminent hardy, deciduous, flowering shrubs, obtaining from about three or four to six or eight feet stature, mostly with slender pliant shoots, some garnished with oblong simple leaves, others with lobated and pinnated foliage; and the branches terminated by spikes and clusters of flowers of very ornamental appearance; hence these shrubs are in good estimation among the curious for embellishing the shrubbery compartments, particularly the first three or four species, which have been long residents of our gardens.

There being seven species of these shrubby *Spiræas*, are all originally from abroad, in different parts of Europe and America, but are

are all hardy enough to succeed in our open plantations.

The chief species are,

¹*SPIRÆA Salicifolia.*

Willow-leaved Siberian Spiræa, or Common Spiræa frutex.] Rises with many upright straight, slender, reddish stems and suckers from the root, three or four feet high; garnished with spear-shaped, obtuse, serrated, naked leaves; and the stalks terminated at top by doubly-branching racemous spikes of numerous pale-red flowers.

This is the most common sort of *Spiræa*, is in high estimation as a flowering shrub; it flowering beautifully in June and July, and frequently the same year's suckers, from the root, flower also in August.

The young shoots of this plant being straight, pliant, and tough, are often used for tops of fishing rods, and riding switches.

²*SPIRÆA Tomentosa.*

Tomentose Red-flowering Philadelphian Spiræa.] Rises with upright, slender, branchy, purplish stems, three or four feet high; spear-shaped, unequally-sawed leaves, tomentose or downy underneath; and the branches terminated by doubly-branching racemous spikes of beautiful red flowers.

Variety.] With white flowers.

Both the varieties flower in June and July, and are very beautiful.

³*SPIRÆA Hypericifolia.*

Hypericum-leaved Canada Spiræa, Commonly called Hypericum frutex] Rises with slender brown stems, branching numerously and slender almost from the bottom, five or six feet high; garnished with oval entire leaves, and numerous small white flowers all along the branches, to the very ends of the twigs, in small close-fitting umbels.

This shrub has singular beauty when in flower, as every branch and twig is closely covered with flowers their whole length; flowering in May and June, continuing very ornamental about a fortnight.

⁴*SPIRÆA Opulifolia.*

Gelder-Rose-leaved Virginia Spiræa.] Rises with many shrubby stems branching six or seven feet high, having a brown loose bark falling off in winter; garnished with lobated or lobed leaves, like the gelder-rose and currant leaf; and numerous white flowers in corymbeous bunches at the ends of the branches.

⁵*SPIRÆA Sorbifolia.*

Sorbus-leaved Siberian Spiræa.] Rises with

shrubby slender stems and branches, three or four feet high; pinnated leaves of four or five pair of folioles uniformly serrated; and white flowers in panicles at the ends of the branches, in July.

⁶*SPIRÆA Crenata.*

Crenated leaved, Siberian and Spanish Spiræa.] Rises with shrubby slender stems, and numerous, slender, brownish branches, four feet high; having oblong leaves serrated at the end, and white flowers in corymbeous bunches laterally from the sides of the branches in May.

All these shrubby *Spiræas* flower here very ornamentally, from May till July, in different species; but rarely ripen seeds in perfection in England; they however are all easily propagated, some by suckers, and all of them also by layers and cuttings. See their *Propagation*.

Herbaceous Kind.

Consists of four floriferous perennials of the fibrous-rooted tribe, rising with herbaceous annual stalks, from one to three or four feet high, garnished with pinnated, ternate, and decomposed leaves, and terminated by cymose bunches, and panicles of flowers; they are all perennial in root, but renew their stalks annually in spring, arriving to a flowering state in June and July, produce ripe seed in autumn, and the stalks soon after decay.

There being four species of these kinds, the two first grow naturally in England, in pastures, &c. and the others are foreigners, but are both very hardy.

⁷*SPIRÆA Filipendula.*

Filipendula, or Drop-wort.] Hath a fibrous root hung with numerous small oval tubers, and crowned at top with a large tuft of pinnated leaves, of many reniform sawed lobes spreading near the ground; and upright herbaceous stalks a foot or more high, terminated by cymose bunches of white flowers.

Varieties.] Common single-flowered *Filipendula* of the pastures, &c. — Double-flowered of the gardens.

The single sort grows wild in England, in pastures and chalky grounds, but is also retained in gardens as a flowery plant, in assemblage with the double sort, which is very ornamental.

They flower in June and July, and the seeds ripen in autumn.

The

The root of this plant consisting of many thready fibres hung with small oval knobs, it obtained the name *Filipendula*.

¹*SPIRÆA Ulmaria.*

Ulmaria; *Meadow Sweet*, or *Queen of the Meadow*.] Hath a thick, fibrated, spreading root, upright, reddish stalks, three or four feet high; garnished with large pinnated leaves, of two or three pair of indented lobes, and an odd one, which is the largest of all, and lobated; and the stalks terminated by large cymose bunches of white sweet-scented flowers, in June.

Varieties.] Common single flowered of the meadows.—Double-flowered of the gardens.—Variegated-leaved.

The common single sort grows wild in most meadows in England, but is often allowed garden-culture along with the double and variegated-leaved sorts; the flowers of all the varieties being very conspicuous, and agreeably scented; but the double sort in particular makes a fine appearance: they flower in June, and the seeds ripen in autumn.

²*SPIRÆA Trifoliata.*

Trifoliata or *three-leaved Virginia Meadow Sweet*.] Hath a fibrated root, upright, branchy stalks a foot high; garnished with almost equally ternate or trifoliate serrated leaves; and terminated with loose panicles of white flowers in July.

³*SPIRÆA Aruncus.*

Aruncus or *Goat's Beard*, or *Austrian Spiræa*.] Rises with upright firm stalks, three or four feet high; garnished with supra-decompound leaves; each division consisting of three or four pair of foliola, and an odd one; and the stalks terminated by paniculated spikes of dioecious white flowers in July.

All the above ten species of *Spiræa* are very hardy, succeed in any common soil and situation, and are of long duration; the shrubby kinds being durable in root, stem, and branches, and deciduous in leaf; but the herbaceous kinds are durable only in root, and renew their stalks every spring; all the sorts, both shrubby and herbaceous, flower abundantly every summer; the flowers separately are small, composed universally of five small petals each, but being numerous and closely placed, are conspicuous to view; but are rarely succeeded by seed in England in the shrubby kinds, though most of the herbaceous kind furnish tolerable plenty in autumn.

As to the merit of all the sorts in gardening, they are all proper furniture for ornamenting the shrubbery, and other parts of the pleasure-ground occasionally.

The shrubby kinds particularly have great merit as deciduous flowering shrubs, for embellishing the principal shrubbery compartments, placing them somewhat forward, in assemblage with other shrubs of equally moderate growth; and here they will exhibit a proper variety, and flower very ornamentally every summer.

And as to the herbaceous kinds, considered as flowery plants, particularly the doubles, are proper for adorning the common borders, &c. where they will flower every summer, and encrease the variety.

Propagation, &c. of the Shrubby Kinds.

The method of propagating all the shrubby kinds is very easy.—By Suckers, by Layers, and Cuttings.

By Suckers.—Several of these shrubby *Spiræas* are productive of many suckers annually from the root, which being taken off in autumn, commence good plants; but the first species in particular, *Spiræa Salicifolia*, *Willow-leaved Spiræa*, or *Common Spiræa frutex*, is remarkably prolific in suckers, that in one summer grow as high as the parent plant, and generally terminated by spikes of flowers the same year in autumn, and should always be cleared off from the old plants every year or two in winter; as should also the suckers of all the other sorts: most of which suckers readily rising with roots, they immediately commence proper plants, and the largest may be planted at once where they are to remain, and the others in nursery-rows, to have one or two year's growth, and will then be fit for the shrubbery.

By Layers.—All these sorts will grow freely by layers, but is a more particularly eligible mode of propagation for any of the sorts that do not readily afford a sufficiency of suckers; for almost every branch or twig being layed down in the earth, in autumn or winter will be well rooted, fit for transplantation by the autumn following.

By Cuttings.—Any of the shrubby sorts will likewise grow by cuttings, though not to be depended upon like layers; however, in October or November, chusing cuttings of the strongest young shoots of last summer's growth, planting them in a shady border,

many of them will grow; and in one or two years commence good plants for the shrubbery.

Propagation, &c. of the Herbaceous Kinds.

All these sorts may be propagated by seed, and by parting the roots.

By Seed.—This may be sowed either in autumn soon after it is ripe, for the greater certainty of having them come up freely in the spring following, or may be sowed early in the spring, as they will also often rise the same year; keeping the plants thin, and clear from weeds till autumn, then planted out either in nursery-rows for a year, or at once, where they are to remain.

By parting the roots.—All the herbaceous kinds may be propagated by this method in autumn, and is the only method of propagation for continuing the double-flowered and striped varieties; observing, of all the sorts, it may be performed either in autumn when the stalks decay, or early in spring before new ones begin to shoot forth.

SPROUTS.

Sprouts are small young shoots or suckers, emitted from the sides of the stem and heads of certain vegetables; being in many instances a compendium of the plant that produced them, and when detached from the parent and planted, although then destitute of roots, they often in the process of vegetation emit fibres, shoot at top to mature growth, and exhibit leaves, flowers, and seed like the parent plant.

Likewise, in some herbaceous esculents, young Sprouts are excellent eating, such as in cabbages, &c. proving a very profitable after-crop.

But the term Sprouts is more generally applied to the lateral shoots or suckers of certain herbaceous vegetables; such particularly, as most of the *brassica* tribe, comprehending all the sorts of cabbages, favoys, coleworts, borecole, purple broccoli, &c. which after the main head is gathered for use, the stalks remaining shoot forth abundance of Sprouts, that often form heads like the principal one but smaller; and, being detached and planted, will grow, or may be gathered for use as esculents, and will prove equally good, and often superior to the main-head for eating.

These Sprouts however, of the cabbage-tribe, have merit chiefly as esculents, and very little in the work of propagation.

For although they will grow if planted while young, they are only proper to be used occasionally in particular cases; as for example, in planting cabbages for seed in any particular good sort, which having the main-head gathered early in summer for use; and the stalk having produced a quantity of good Sprouts soon after, we sometimes slip off a quantity of the best of them towards autumn, plant them in rows two feet asunder, giving occasional waterings, will grow and shoot up to seed next spring. See **BRASSICA.**

However, the Sprouts of all the cabbage-tribe, considered as esculents, are admirable fine eating, generally boil exceeding green and tender; but those Sprouts produced from the forward cabbage stalks in summer and autumn, are always larger and finer than the winter and spring Sprouts, as sometimes the Sprouts produced on the stalks of the early-cut cabbages, often also cabbage into tolerable little firm heads towards autumn; the sugar-loaf cabbage particularly, producing abundance of fine Sprouts in summer, which being gathered while young and green, are some of the most excellent culinary greens of the season; likewise forward favoys being cut early in autumn, the remaining stalks produce fine large sprouts the same year, fit for use in the early part of winter; later crops of the same plants produce also abundance of small Sprouts in the spring; and the borecole is remarkable for its great production of Sprouts towards spring, emitted all along their tall stems from the very bottom to top; also purple broccoli never fails to produce a secondary crop of excellent Sprouts furnished with little tender heads.

Thus all these cabbage and colewort tribe, that after the main-heads being arrived to perfection and gathered for use, the stalks furnish a plenteous supply of Sprouts, coming in for a second crop; those produced in summer and autumn continuing long in perfection; but the spring Sprouts run smaller, and continue but a short time before they fly up for seed; they are nevertheless very acceptable and useful, at that season of the year.

Therefore, in the culture of all the above varieties of the cabbage kind, it is proper after gathering the main-heads, to leave a quantity of the stalks of the best and forwarder crops, of the respective sorts, to produce

duce Sprouts; and if towards autumn or winter, &c. the ground should be wanted for other crops, the stalks may be removed and trenched in by the roots in another place, not in any shady bye corner as often practised, nor placed too close, as the Sprouts would prove small and trifling, and be liable to be eat up by slugs; but being placed in an open situation, in rows a foot asunder, the Sprouts will continue their growth in much greater perfection, though probably not equally so good as if the stalks had remained undisturbed.

Thus the product of Sprouts will prove a very beneficial and acceptable supply, both for usefulness and variety at table.

The stalks of cauliflowers and cauliflower-broccoli, rarely produce any Sprouts, so it is needless to leave them standing.

STAMINA, the male organs of flowers.

Stamina, consisting of the filaments and antheræ, the male organs of every flower; being the fine chives or thread-shaped parts situated in the center of the *corolla*, in number from one to twelve, or twenty or more; and composed of the three following parts.

¹*Filamentum*, the filaments or thread-shaped parts elevating the antheræ. See FILAMENTUM.

²*Antheræ*, the summit of the filaments, and that part which contains the *pollen* or fecundating dust or farina. See ANTHERÆ.

³*Pollen* or farina, the fine dust, or fecundating male sperm contained in the antheræ; and when ripe, dispersed upon the stigma or female organ, to effect the important office of impregnation.—See ANTHERÆ and FILAMENTUM, &c.

It is observable in most flowers, that the Stamina and pistillum come together; and the antheræ and stigma ripen and becomes of full vigour at the same time to effect the work of fecundation.

For the Stamina containing the genuine male sperm of plants in the antheræ, that without its fecundation aid no plants would be effectually prolific, but mostly abortive; at least, if they produce seeds, they would not vegetate.

In hermaphrodite plants the *Stamina* or male organ being placed in the same flower with the female genitals, are for the most part all of equal height, generally surrounding the pistillum in such situation, as the farina or male sperm lodged in the antheræ, may readily reach the *stigmata* of the female flower

to impregnate it effectually; but in some hermaphrodite flowers the pistillum being shorter than the Stamina, the flowers though nodding before, upon opening generally stand upright, that the powder of the antheræ may fall upon the stigma; and after conception probably resume their drooping or pendulous posture again; and in other hermaphrodite flowers having the style longer than the Stamina, it either bends back like ram's-horns towards the antheræ, or the whole flower droops that the antheræ may drop its dust down upon the female organ. See HERMAPHRODITUS *flos*.

In monoecious plants, the Stamina and pistillum are in different flowers, situated apart on the same plant, as in cucumber and melon; but in many sorts have the male flowers mostly placed above the female, that the farina or fertilizing powder may more readily fall on the stigma of the pistillum: or so situated as to be easily conveyed by the air or flying insects, skipping from flower to flower, sufficiently to effect the impregnation. And in some plants, such as cucumbers, growing in hot-beds at an early season, we often perform the fecundation by art, carrying the male blossom to the female, and discharge the contents of the antheræ upon the stigma; but when the warm season is advanced to admit of the plants being fully exposed, that operation is effected by the air, or bees, conveying the prolific dust of the antheræ to the female blossom. See CUCUMIS and MONOECIA.

And in the dioecious plants the Stamina and pistillum are in separate flowers, situated on different plants, species of the same genus, as in spinach, hemp, hops, &c. but so wonderfully contrived by the great Author of Nature, that the male dust of the antheræ is conveyed to the female flowers by the gentle breezes of air, &c. and impregnate them. See the Class DIOECIA, under the head CLASSIS. See also SEXUS, PISTILLUM, STIGMA, and STYLUS.

STANDARD Trees.

Standard-trees are to be considered as all trees with upright single stems, and stand detached without being trained to any wall, &c. or other support.

The name Standard-trees is applicable both to all sorts of fruit and forest-trees, and all other tree and shrub kinds that, having upright stems, stand detached erectly without aid of support; though the word Standard

Standard is more generally understood of such trees as grow with tall erect stems, six or eight feet high, or more, before they branch out to form the head; such as the common Standard apples, pears, and other fruit-trees in orchards and gardens, and the common forest-trees of the woods and fields; in gardening, however, we commonly distinguish three sorts of Standard trees; namely, Full Standards, Half Standards, and Dwarf Standards; fruit-trees particularly, being occasionally trained in all these ways; but forest and tall ornamental trees rarely in any other than Full Standards; though in the shrub tribe they are occasionally formed both into half and Dwarf Standards, according to their natural stature of growth. See each as below.

FULL STANDARDS.

Full Standards—These are such trees that are trained with tall, straight, clean stems, six or seven feet high or more, clear of branches, then suffered to branch out at that height all around to form a head, as in common Standard apples, and pear-trees, forest-trees, &c.

All trees designed as Full Standards, should be trained accordingly in their minor state, by trimming off all lower laterals gradually as the stem advances in height, to encourage a clean straight growth to the proper height, and promote the aspiring of the top or leading shoot more expeditiously; suffering the leader always to remain entire, especially in all forest-trees; or if it should happen to fork, take off the worst, and leave the straightest shoot to run up, to continue the prolongation of the stem; and having thus run them up with clean stems six or seven feet, suffer them at that height to branch out into a head, and run in height as fast as possible; though in fruit-trees the stem is often topped at six or seven feet height, to force out a set of laterals in that part, to form a regular spreading head of but moderate height, for the greater convenience of gathering the fruit: however, for all kinds of forest-tree Standards never reduce the top, but permit the leader to remain ever entire to run up in height; for the beauty and worth of such trees consists in their lofty stature.

However in several forest and ornamental Standards of the evergreen-tribe, the trimming their stems from laterals while young, as above, must be but sparingly practised; such as the pines, firs, cedars, and several others of the coniferous tribe, which being

all of a resinous nature, do not succeed if too close pruned; so in training all these sorts of standards, trim only any lower stragglers occasionally. Besides, the disposition of the branches of these sorts covering the stem in circular rays to the very bottom, is thought additionally ornamental in their growth.

Almost all sorts of fruit-trees may be trained for full Standards, except vines, though all sorts will not ripen their fruit on Standards in this country; such as peach, nectarines, apricots, and figs; on the other hand, all sorts of apples, pears, plums, and cherries, ripen their fruit freely on Standards.

All fruit-trees designed as full Standards, are raised by grafting, &c on the freest strong-shooting stocks, and trained with straight clean stems full five or six feet high, either the stock trained up to that stature, and so grafted or budded at the desired height, and the graft or bud branching out forms the head; or the stock may be grafted, &c. near the ground, and the first shoot from the graft or bud, trained up for a stem to the height aforesaid; then suffered to send forth branches: observing in either method, it is next to be considered whether you intend the tree shall form a spreading open head, or assume a more erect and aspiring growth; in the former case, if you top the leading shoot of the graft or bud, at six or seven feet from the ground, it will force out lateral shoots at that height, and commence a spreading head open in the middle, suffering however, the whole afterwards to take their own growth; and in the second instance, that by permitting the leading shoot to remain entire, it will aspire in height, and the whole head will assume a more upright and lofty stature; in both methods the heads will afterwards naturally branch out abundantly, and furnish themselves sufficiently with bearing wood, producing fruit in two or three years from the grafting and budding; suffering them generally to take their own growth without shortening, and but very little other pruning, except the regulating any very irregular or bad growths, as below.

It being expedient to train most of our principal hardy fruit-trees as full Standards, as that when planted in continued rows, either in gardens or orchards, by having tall stems elevating the head considerably from the ground, it both admits the influence of the sun and air more freely to the head all around; and admits of obtaining crops of esculents,

esculents, grafs, &c. on the ground, under their spreading branches.

With respect to the general culture of full Standard fruit-trees, in regard to pruning, &c. very little is required after the first training, to form the stem to the proper height, and the first shoots advanced at top to give the head its first formation; they should afterwards generally be allowed to take their own growth, except reducing any very irregular growths, &c. not shortening the general branches, but permit the whole to shoot both in length and branch laterally in their own way; and they will thus all naturally form fruit spurs all along their sides upward for bearing; remarking, however, when any very irregular growing branch occasionally occurs, it should be retrenched; also if the head is much crowded, some should be judiciously thinned out to keep the middle open, long ramblers reduced, and all suckers from the root, stem, and middle of the head, cleared away, and all dead wood; which occasional prunings may be performed any time in winter.—See the culture of different fruit-trees, as apples, pears, plums, cherries, &c. under their proper heads; also PRUNING.

But sometimes Full Standard fruit-trees are also planted against walls, and trained as wall trees; this being frequently practised for high walls, as the Standards having tall stems elevating the head six or eight feet, so as immediately to cover the upper part of the wall, whilst dwarfs and Half Standards cover the bottom and middle part, and thus may every part of the wall be fully occupied at once; but the dwarf-trees being designed as the principal residents, that after they begin to advance considerably, and the Standards having borne a few years, the latter have their under branches gradually reduced to make room for the dwarfs, and at last are either wholly transplanted or destroyed, leaving the dwarfs in entire possession of the wall, covering it effectually from bottom to top with their branches. See the different sorts of wall-trees, as peaches, nectarines, apricots, &c. — Also the article WALL-TREES.

HALF STANDARDS.

Half Standards.—These are trees trained with short stems only three or four feet high, then suffered to branch out at that height to form heads; being practised for many sorts of fruit-trees, sometimes both as detached

Standards by way of variety, and by having low heads the fruit is more easily gathered; and likewise are often designed as wall-trees for high walls; that, as observed of the full Standards, they may cover the middle or upper part of the wall, whilst dwarfs occupy the lower part.

As to the method of raising these Half-Standard fruit-trees, it is nearly the same as observed for the Full Standards only, they being grafted, or budded upon lower stocks, training them with upright single stems only three or four feet high, either the stocks on which they are to be grafted trained up to that height for a stem; or being grafted or budded low in the stock, and the first main shoot of the graft, &c. led up for a stem, and so top it at the aforesaid height to force out branches to form the head; suffering the head in all those designed as detached Standards to branch out all around, and permitted to run up to a full spread, nearly according to their natural mode of growth, except just reforming any ill-growing branch, as hereafter noticed; for shortening the branches should be very sparingly practised, which would force out numerous useless shoots, and prevent the formation of bearing wood, especially in the apple, pear, plum, and cherry kinds; remarking those intended for walls should have the head trained in a somewhat fanned manner, to spread to the wall like a common wall-tree; and as to the after-pruning, the same is to be observed as hinted in the general culture of the respective sorts under their proper genera, whether in detached Standard or against walls.

It may sometimes be proper to have these Half Standards so trained as to form heads of as moderate growth as possible, especially the detached Standards, when designed for small compartments; in which case they are grafted or budded upon the more dwarfish sort of stocks, as apples upon codlins, and pears upon quinces, and so of other fruits; in which the head will always shoot moderate, and never ramble wide or grow high. See STOCKS.

But although a few Half Standard fruit-trees may be eligible as detached Standards for variety, they are not proper for any general plantation in the open quarters of the garden; because their branches coming out low may impede the growth of under-crops; may however have a range thinly planted along the boundary or division of any wide compartment, and their heads

suffered

suffered to run as hinted for the Full Standards.

For walls however that are eight or nine feet high, it is very proper to have a sufficiency of Half Standards to plant between the dwarfs or principal residents, to cover the middle or upper half of the wall, whilst the dwarfs occupy the lower space, as remarked of the full Standards.—See WALL-TREES.

Half Standard fruit-trees are also proper to plant in forcing frames to produce early fruit. See FORCING FRAMES.

The culture of detached Half Standards, in respect to pruning, is nearly as the Full Standards; that having shot out at top to form the head, permit them to branch away both in length and laterally nearly in their own way, except just reducing any considerable irregularity, crowding branches in the middle, long ramblers, and all suckers from the root, stem, and head, and all dead wood; and thus the regular branches remaining at length, will emit fruit-spurs abundantly in every part for bearing.

And as to the Half Standards against walls, they are to be pruned and managed as other wall-trees, each according to its nature, as directed under their proper heads.

Forest-trees, and the taller ornamental tree kinds, are rarely ever trained as Half Standards, but mostly always suffered to run up in height to their full stature, unless any particular sort may be required to form bushy Half Standards for some particular purpose; in which case if topped at three, four, or five feet height, it will branch out into a bushy head.

Many of the shrub kind in their natural growth assume the appearance of Half Standards, though some are often branchy to the very bottom, or rise with several stems; but might readily be trained with a single clear stem, three or four feet high, and then suffered to branch out into a full head.

DWARF STANDARDS.

Dwarf Standards.—They are trained with low stems only one or two feet high, being then topped to force out branches at that height to form the head.

Formerly several sorts of choice fruit-trees were trained as Dwarf Standards, with stems seldom more than one foot high branching out at that height, forming proportionably low heads; being generally planted round the great quarters of the kitchen-garden, &c.

instead of espaliers, and the heads kept down low by close pruning, whereby they never produced much fruit; they however greatly prevailed in ancient gardening, and consisted of three sorts.—Concave dwarfs, having the middle of the head hollow or concave.—Convex dwarfs having the head full from the middle all round.—Horizontal dwarfs, having all the branches extended all round, in a flat or horizontal position; but the concave dwarf was in most esteem; all of which Dwarf Standards being raised by grafting, &c. upon the most dwarfish stocks, such as apples on paradise stocks, and pears on quinces, &c. in order to dwarf them as much as possible in their growth (see STOCKS); and as they shot in height, each year's shoots were generally pruned short; and to keep the head down, and confine it within a small compass; but by this severe pruning, they were forced into numerous useless shoots annually, and seldom formed a sufficiency of bearing wood; so that they never answered the end effectually; and their branches growing so low, no small crops could be obtained on the ground under them, on which consideration they are become in disrepute, especially since espaliers have been brought to such perfection.—See DWARF TREES and ESPALIERS.

However, for the sake of variety and curiosity, a few Dwarf Standards of all sorts of fruit-trees might be admitted, one here and there, and by a judicious moderate pruning, according to their nature as directed for the respective sorts under their proper heads, and the article DWARF TREES, they will bear abundantly in proportion to their size.

Likewise may have some Dwarf Standard fruit-trees in pots, for the purpose of forcing in hot-houses, forcing-frames, hot-beds, &c. particularly early May, and May duke-cherries, nutmeg-peaches, masculine apricots, figs, vines, gooseberries, currants, &c. which being placed in the above departments at the proper season, i. e. January or early in February; they will often ripen a few fruit very early in tolerable perfection, which might be brought to table growing on the trees in the pots. But dwarf Standard fruit are also proper to plant fully in the borders in forcing frames. See FORCING-FRAME.

For the particular method of raising and training the different sorts of these Dwarf Standards. See DWARF TREES.

Numbers of the upright shrub tribe naturally form themselves of the Dwarf Standard kind,

kind, as rising with low, erect, firm stems, perhaps but half a foot, or a foot or two high, branching out near the ground into bushy heads, such as the gooseberry, currant, and numerous flowering shrubs and evergreens; though great numbers of the shrub kind are apt to rise with several stems immediately from or near the root, forming a bushy growth quite from the bottom, which in many cases in the shrubbery way may be allowable; in others, it may be proper to train them with one stem, which is easily effected by retrenching the superfluities and trimming away low stragglers, forming a clear single stem half a foot, or a foot or two high, according to their nature, then suffered to branch out into a full head.

For many of the low Standard flowering shrubs and evergreens appear to the best advantage, when trained as Standards to a single stem a foot or two high, terminated by a branchy full head.

Likewise, all the fructiferous shrubs, such as all the varieties of currants and gooseberries, should generally be trained with a single stem a foot or more high, then permitted to branch out at that height into a regular head, keeping the internal part always tolerably open, and the branches moderately thin, and shorten them but sparingly, particularly the gooseberry.—See RIBES.

STAPHYLÆA, Bladder-nut.

Two hardy deciduous flowering shrubs compose this genus, both of which are proper furniture for the shrubbery, being of largish upright growth, generally obtaining eight or ten feet stature, adorned with pinnated and ternate five, and three-lobed leaves; and long slender bunches of pentapetalous flowers, succeeded by bladder-like capsules; whence the name Bladder-nut.

Class and order, *Pentandria Trigynia*.

Characters.] CALIX, is roundish, concave, coloured, and almost as large as the corolla.—COROLLA, five oblong erect petals, nearly like the calix, and a pitcher shaped nectarium at the bottom.—STAMINA, five oblong erect filaments, crowned with simple antheræ.—PISTILLUM, a thick three-parted germen, and three styles, having obtuse stigmas contiguous.—PERICARPIUM, three inflated shaped-shaped capsules, joined together by a longitudinal future or seam, having acuminate tops, and open inwardly,

inclosing two almost globular, hard, nut-like seeds.

There are only two species, both very hardy deciduous shrubs, the first of which is a native of England and other parts of Europe, the other is from America; are distinguished by the names of five-leaved, and three-leaved Bladder-nut.

The species are,

¹STAPHYLÆA *Pinnata*.

Pinnated five-lobed European Bladder-nut.—

Rises with upright, shrubby, smooth, brownish stems, branching eight or ten feet high or more, with very pithy shoots; garnished with pinnated leaves of two pair of large, oblong, oval lobes, and an odd one; and at the axillas along the sides of the branches, long pendulous bunches of white flowers, succeeded by large, inflated, or swollen, bladder-shaped capsules, containing roundish hard seeds or nuts ripening in autumn.

This sort grows wild in England, and many other parts of Europe; and is cultivated in gardens to encrease the variety, in ornamental plantations, where it flowers and ripens seed annually.

The seeds or nuts are in some countries eaten, but have a very unpalatable relish.

²STAPHYLÆA *trifoliata*.

Trifoliate or Three-leaved Virginia Bladder-

nut.] Rises with upright, shrubby, smooth, greyish stems, branching eight or ten feet high; garnished with ternate or trifoliate leaves, being composed each of three large oval lobes; and at the sides of the branches, long, hanging bunches of white flowers, succeeded by large inflated capsules, containing roundish hard seeds, ripe in autumn.

Both the species flower annually in May, numerously in pendulous bunches, each flower having five oblong petals; and the seeds ripen in autumn, proper to sow for propagation.

These shrubs are very eligible furniture for diversifying any of the hardy ornamental deciduous plantations, but particularly the larger shrubbery compartments, where being planted in assemblage with other shrubs, principally of the deciduous tribe, they will agreeably multiply the variety with their pentaphyllous and ternate foliage, long pendulous bunches of flowers, and bladder-shaped capsules, which exhibit a singular appearance in autumn.

Method

Method of Propagation.

The propagation of both these shrubs is most easily accomplished by three or four different methods, viz. by seed, suckers, layers, and cuttings.

By Seed.—This ripens plentifully in autumn, when it should be sowed soon after it is ripe, in a bed or border of any common earth, either in drills or promiscuously on the surface, covering them near an inch deep; and being thus sowed early in autumn, they will come up the following spring, though probably not all of them till that time twelvemonth, keeping them clean from weeds; and, if in the early part of summer, very dry weather prevails, refresh them with frequent waterings, repeating those operations during summer as occasion may require; and by autumn or spring following, the largest plants will be fit to plant out in nursery-rows, or at least in the second autumn they may be wholly planted out, placing them in rows two feet asunder, and one foot distance in each row; here to have two or three years growth, or till wanted for the shrubbery, &c.

By Suckers.—The plants of a few year's standing generally send up suckers from the bottom in tolerable plenty, which may be easily taken up in autumn or winter with roots, and planted in nursery-lines, to have one or two years growth, then transplanted into the shrubbery, when required.

By Layers.—In autumn or winter chusing the younger branches, lay them either by slit or twist-laying (see *LAYERS*), and they will be properly rooted by the following autumn; when they should be planted off in nursery-rows for a year or two, to gain due strength for the shrubbery.

By Cuttings.—In October or November procure a quantity of young shoots of the former summer's growth, chusing principally the lower part of the shoots; plant them in a shady border, giving occasional waterings the following spring and summer in dry weather, and they will be mostly well rooted by the following autumn.

STATICE, Thrift or Sea Pink, and Sea Lavender.

Consists of low, hardy, herbaceous, and under-shrubby plants for ornament and variety; some of which being flowery perennials are employed in the decoration of the

pleasure ground; they rising, some sorts with very low, close, tufty heads, of numerous, small, narrow, grassy, evergreen leaves close to the earth, and very slender single flower-stalks but half a foot, or a little more or less high; others having much larger, broad, radical leaves, and stronger stalks dividing into branches; all the stalks and branches of the sorts in general terminated with globular and spiked aggregate heads, of numerous small, infundibuliforme, pentapetalous flowers.

Class and order, *Pentandria Pentagynia*.

Characters.] CALIX, an aggregate of florets collected into globular or spiked heads, included wholly in one common cup of divers structures in the different species, each floret having also its proper calix, which is monophyllous and funnel-shaped.—COROLLA, is funnel shaped, consisting of five small petals, narrow at the base; but broad, obtuse, and spreading above.—STAMINA, five subulate filaments that adhere to the unguis or claws of the petals, and incumbent antheræ.—PISTILLUM, a small germen, and five filiform distant styles, crowned with acute stigmas. PERICARPIUM none, the seeds one in each floret, are lodged in the general calix, each seed coronated by its own proper cup.

Since to this genus has been added the *Limonium* or Sea Lavender, the species are multiplied to fourteen in number; the first of which is the common Thrift or Sea Pink, a small hardy herbaceous evergreen, well known to all for its use, occasionally as an edging to borders, &c. comprehends several varieties, all very low, close-growing, grassy-leaved plants: the other thirteen species, being mostly of the Sea Lavender kinds, are of larger growth, with broadish leaves; and consist of herbaceous and under-shrubby perennials and annuals; but not possessing any great merit for general garden culture, are not much attended to; so that only one species, common Thrift, and varieties above hinted, are commonly cultivated: however, some of the most material of the Sea Lavender kinds, as below, may also be introduced for variety where large collections are required.

Common Thrift Kinds.

One species only comes under this head, comprising however several varieties; some of which were formerly considered as distinct species,

Species, but prove all varieties only of *Statice Armaria*, or common Thrift, differing somewhat in their size and colour of the flowers, as noticed below.

¹STATICE *Armeria*.

Armeria, Common Thrift or Sea Pink.]

Hath a thick, fibrated, spreading, perennial root, dividing into heads at top, closely crowned with thick tufty heads of numerous linear, grassy, evergreen leaves close to the ground; and among them numerous slender single stalks, from five or six to eight or ten inches or more; each crowned with a globular aggregate of red and other coloured flowers in the varieties, appearing in June and July.

Varieties.] Common smaller Thrift with pale-red flowers.—With scarlet flowers, and with white flowers.—Greater Thrift with red flowers.—Greater Thrift with white flowers.—Least Sea Pink with small flesh-coloured flowers.—All of which flower profusely from the end of May until July or August.

Remarking, as to the difference in size and growth of these varieties.—The common smaller Thrift is distinguished by its leaves being more narrow, grassy, and of lower growth, and the flower stalks only five or six inches high, being the sort most commonly used for edgings; the greater Thrift having longer and broader leaves, and flower-stalks near a foot high; and the least Thrift have exceeding narrow, short leaves, flower-stalks only three or four inches high, and very small heads of flowers.

All the sorts are inhabitants of plains and meadows, chiefly near the sea in most countries in Europe and North America; but have been long admitted into gardens as flowery plants, and were formerly in great estimation to plant for edgings to beds and borders, as being of very low close growth, and always green: and also to plant in tufts about the flower borders and other compartments of the pleasure ground, as they succeed in any soil and situation, and flower very abundantly in June and July, making a good ornamental appearance, more particularly the red and scarlet sorts; but they make the grandest show when disposed in long close ranges, either in single rows, as edgings to borders along the sides of the walks, or in one or more ranges together, extended lengthways, of any bed or border in some conspicuous situation; and for all of

which purposes they are very expeditiously raised by slipping the heads and roots at almost any season, but principally in autumn and spring.—See their *Propagation*.

However, for edgings in particular is the principal merit of these plants, and as they grow very close, low, and continue in verdure all the year, they form the most useful and eligible edging, next to box; and in some cases, in rural works particularly, are sometimes preferred to box edgings, especially as they flower very ornamentally for two months in summer; but are not however so proper for general use; as being rather apt to spread soon out of bounds and require to be reduced, either by cutting it inconsiderably on each side, or by taking it up and replanting it afresh every two or three years.—See EDGINGS.

Sea Lavender Kinds.

These sorts assume a different appearance from the common Thrift kinds, both in their foliage and mode of flowering; their leaves not being so small and grassy, but mostly plane and broadish, and the stalks generally dividing into panicles terminated by the flowers, not in globular heads like the Thrift, but chiefly in spiked aggregates; but their general *characters* proving the same as in the Thrift, they are all considered as true species of *Statice*.

²STATICE *Limonium*.

Limonium, or Sea Lavender.] Hath thick, reddish, fibrated roots, crowned with oval, spear-shaped, smooth leaves; and upright, firm, taper, naked stalks a foot or more high, dividing into paniculated branches, all terminated by spiked heads of pale-blue flowers, in July and August.

Varieties.]—Common great Sea Lavender.—Narbonne great late-flowering Sea Lavender.—Olive-leaved Sea Lavender.—Deep blue-flowered Sea Lavender.—White flowered Sea Lavender.

This species grows naturally on the sea-shores of England, &c. and is sometimes retained in the gardens for variety.

³STATICE *Tartarica*.

Tartarean Sea Lavender.] Hath long, spear-shaped, sharp pointed leaves; and forked, branchy, spreading stalks six or eight inches high, terminated by spiked heads of whitish alternate flowers at a distance, in August and September.

⁴STATICE *Reticulatum*.

Netted Sea Lavender.] Hath cuneiform or wedge-shaped lower leaves; prostrate slender stalks, and retroflexed naked sterile branches netted or matted together; and the stalks terminated by panicles of pale blue flowers, in July and August.

This is a sea-side plant of England, and most parts of Europe.

⁵STATICE *Cordata*.

Cordated or Heart-leaved Mediterranean Sea Lavender.] Hath thick, spatulate, heart-shaped, retuse, smooth leaves close to the ground; and slender naked stalks six inches high, terminating in panicles of pale red flowers, in August.

⁶STATICE *Flexuosa*.

Flexuose Siberian Sea Lavender.] — Hath oval nervous leaves from the roots; and weak, flexuose, branchy stalks eight or ten inches long, terminated by corymbus bunches of flowers, in August and September.

⁷STATICE *Suffruticosa*.

Under-shrubby Siberian Sea Lavender.] Hath under-shrubby stalks, naked and branching near the top, rising near two feet high; spear-shaped variegated leaves; and close-sitting round heads of pale-blue or whitish flowers, in August and September.

All these seven species, both of the Thrift and Sea Lavender kinds, are very hardy fibrous-rooted perennials, six of them being herbaceous, and the seventh is under-shrubby; all of which flower abundantly in summer, but not all very ornamentally; the flowers are numerous, but separately small; and are universally funnel-shaped, and pentapetalous; and many collected together into aggregates, within one general cup (see the *characters*); being generally produced at the ends of the stalks and branches, in some singly, in others in panicles as before described in each species; but are not all commonly succeeded by seeds in the gardens.

The first species, *Statice Armeria*, and varieties, being considerably the most material, both for their use as edgings, and flowering plants, are almost the only species of this genus that is generally cultivated.

The other six species are at present not common in the gardens, except in those of some curious botanists for observation and variety; however, all the sorts of them that can be obtained, may with propriety be admitted, to encrease the variety, as they take

up but little room, will grow in almost any common soil and situation, though if but moderately exposed to the sun, they will probably be the more successful and durable.

All the sorts, both the Thrift and other kinds, may be planted any time in autumn or spring.

The Thrift kinds, as we before noticed, are proper both to form edgings, and to plant in detached tufts about the borders: the scarlet Thrift is the most beautiful in regard to its flowering, but for variety should also admit the pale-reds, and white kinds, all of which succeed almost any where, and may be planted at almost any season when not in flower; though the autumn and spring are the most successful seasons for planting them.

As to the method of planting Thrift edgings, a quantity of slips being obtained in the seasons above-mentioned from old plants, by slipping or dividing the off-sets of their roots, not however too small, and each slip furnished with roots and top; then having made up the edge of the bed or border even and firm, proceed to plant them with a dibble in one range, two or three inches distance in the row; or to form at once a close edging, may plant them so near as to touch one another; and some, to perform this more effectually, form a small trench, as in planting box edgings; so plant the Thrift in the trenches quite close together, to form immediately a compact uniform edging, in the manner of a box-edging aforesaid. See *BUXUS*, *SUFFRUTICOSA*, and *EDGINGS*.

And as to the culture of these edgings, they should every summer immediately after flowering, be trimmed with garden-shears or the like, to cut off all the decayed flower-stalks close to the bottom; likewise, to trim in any projecting irregularity of the edging at sides or top: also when it spreads considerably out of bounds, should be cut in evenly on each side, in due proportion; observing to perform those occasional trimmings generally in moist weather, and not too late in autumn, otherwise the drought of summer, or the cold in winter may injure it when newly cut, and cause it to assume a shabby disagreeable appearance.

Observe however, that when these edgings grow considerably out of bounds, or become very irregular, it is proper to take them up,

slip

slip the plants small, and immediately re-plant them again as before, in a neat regular edging.

Sometimes these edgings require replanting, as above, every two or three years.

Method of propagating all the Species.

All the sorts are very easily propagated, by slipping or parting the roots, in autumn and spring.

Thrift kinds.—All the varieties of Thrift propagate abundantly by off-sets of the root and head; which in early autumn, or in the spring, &c. may either be slipped off from any growing plants, or any large old plants taken up and wholly divided, each into as many separate slips, as it admits preserving the root and top to each slip; and plant them directly, either in an edging or where wanted.

Sea Lavender kinds.—They may be propagated by parting their roots, in autumn or spring; also some of them by slips or cuttings of their shoots in summer, planted in a shady border, or shaded and watered, and they will be rooted by autumn.

These sorts may also be raised from seeds when they can be obtained from the places where they ripen, in England and abroad; sowing them in autumn, or early in spring on an east border, and in warm dry weather give frequent waterings, both before and after the plants come up; and in autumn plant them out.

STELLATA, or Starry Plants.

Such as have their leaves disposed in rays or whirls round the stem at intervals, and point different ways like the figure of a radiant star; exemplified in *Rubia tinctorum*, or common madder, &c.

STEWARTIA, *Stewartia*.

There is but one species, a hardy deciduous flowering shrub from North America, proper for the shrubbery compartments, rising several feet high, adorned with largish simple leaves, and large pentapetalous flowers.

Class and order, *Monadelphia Polyandria*.

Characters.] **CALIX**, is monophyllous, divided into five oval-spreading segments, and permanent.—**COROLLA**, five large oval, spreading petals.—**STAMINA**, many filiform monadelphous filaments, being united into a cylinder at bottom, connected to the petals at their base, and crowned with roundish incumbent antheræ.—**PISTILLUM**, a roundish

hairy germen, five slender styles, having obtuse stigmas.—**PERICARPIUM**, a quinquelobate pomaceous capsule of five cells, each having an oval compressed seed.

STEWARTIA *Malacodendron*.

Stewartia or *Malacodendron*.] Rises with a shrubby stem branching irregularly on every side, eight or ten feet high, having the branches covered with a brownish bark; oval, spear-shaped, sawed, veined, alternate leaves, two or three inches long, and half as broad; and at the sides of the branches large white flowers, having numerous purple stamina surrounding the five styles; flowering early in June, but do not perfect seeds in England.

This elegant shrub is a native of Virginia, from which country it was introduced into our gardens to encrease the variety in the shrubbery collection; though it is not as yet near so plentiful here as many other American shrubs; but is raised in most of the nurseries for sale.

It is a hardy shrub, though young seedling plants of it are rather a little tender, the first year or two requiring shelter from frost, but after having acquired more strength, will stand very well in the open shrubbery the year round.

It is propagated by seed and by layers, and sometimes by cuttings.

By Seed.—This the seedsmen procure annually from abroad; sow it as soon as possible in pots of light earth half an inch deep, and plunge them in a hot-bed, either of dung or bark, under glasses, giving occasional waterings, and moderate shade from the sun, both before and after the plants come up; being careful to harden them gradually in due time to the open air in summer; but in winter place them under a garden-frame, to remain till spring; when, in order to forward them as much as possible, may plunge them again in a bark-bed for a month or two, till towards summer, then gradually hardened, and plunged in a shady border till autumn, at which time removed again under shelter all winter; and in March following, may pot them off separately into small pots plunging them also in a bark-bed to strike them more expeditiously, bestowing proper waterings and occasional shade; not forgetting to harden them as before, and indulge them with shelter another winter or two; and in spring following, when the weather is settled, may

may venture to turn them with the balls of earth about their roots into the full ground.

By Layers.—Chuse the young shoots for laying, which may be performed early in autumn, generally by slit-laying; and in the following spring and summer in dry weather, do not fail to give frequent waterings; and if indulged with a moderate shade in the heat of summer, they will root more freely, which they sometimes effect in one year, when in March pot them off separately; and if then plunged in a bark-bed, or in any moderate heat for a few weeks, will forward them considerably; removing them to a shady border all summer, to shelter of a frame in winter; and in spring after, transplant them with balls into the open ground, finally to remain.

By Cuttings.—Young shoots in spring and summer being planted in pots of good earth, and plunged in a bark-bed, some of them will probably strike and commence proper plants, which must be timely inured to the open air, and managed as the seedlings and layers.

STIGMA of the flower,

Is the extremity or summit of the pistillum, or female organs of flowers.

The Stigma forms the head or summit of the style, and is accounted the principal female organ of plants, designed for the reception of the farina or fecundatory dust of the antheræ or male organs, which being discharged upon the moist Stigma, the particles burst, and shed their fertilizing seminal virtue; and being absorbed by the Stigmata, its effluvia or essence is transmitted through the style or vagina, into the heart of the germen, ovary, or seed-bud, for the purpose of impregnating the seeds.—See PISTILLUM, FILAMENTUM, and STYLUS.

As to figure, the Stigma is various in different plants; it being in some formed into a round or globular head; in others, it is either oval, orbicular, angular, crown-shaped, target-shaped, cross-shaped, stump-shaped, hook-shaped, petal-shaped (as in *Iris*), obtuse, depressed, concave, channelled, ribbed, streaked, feathered, hairy, downy, &c.

In respect to number, the Stigma is either single or but one, as in the generality of flowers; bifid or two, as in lilac; three, as in *campanula*; four, as in *epilobium* or French willow-herb; five, as in some plants.

With regard to situation, the Stigma generally terminates or crowns the style, as in

most plants; sometimes when there are many Stigmata, they are disposed with admirable symmetry along the sides of the style; and when the style is wanting, as in poppy and some other flowers, the Stigma rests immediately on the germen or seed-bud.

In general, the surface of the Stigma is covered with a viscous or clammy moisture, serving to attract, retain, and dissolve the particles of the fecundating powder, and thereby more easily transmit its effluvia to the seeds below.

For in the vegetable kingdom the genital dust of the antheræ being carried by the air to the moist Stigmata, where the particles burst, as before observed, and discharge their exceeding fine or subtle contents, and impregnate the ovary; as is often obvious to sight in many plants when in flower, and the farina flying about, that part thereof lights upon and clings to the Stigma; which some flowers shew in a most agreeable manner, such as in the pansies, that when the flower is scarcely opened, we shall see the Stigma like a concave globe gaping open on one side, and of a pure white colour; but as soon as the antheræ of the five stamina have discharged their genital male dust, you may observe the whole Stigma filled with this dust, or fertilizing powder, and covered all over with a yellowish-brown colour.

With respect to duration, the Stigma most commonly withers after the impregnation is effected, except in some few genera, such as poppy and water-lily, &c. in which the Stigmata is permanent or abiding.

STIPULA of the leaves, &c.

Is a scale or very small leaf on each side the base of the foot-stalk of some leaves and flowers.

These Stipula are defined to be one of the *fulcræ* or props of plants, designed to support more firmly the bud of the leaf, &c. on which they are attendant, as they are generally stationed one on each side; though some plants have only one, and a great many none at all; they are however common to a great number of plants, both trees and herbaceous vegetables; their situation is mostly on the outside of the leaves, and in some few plants on the inside; being of divers figures, and sizes in different species; and in some plants they grow free, loose, and detached; in others, they grow close to the plant; in some plants they are deciduous or

fall off before the leaves; others are permanent, continuing till the general fall of the leaf.

Thus the *Stipula* often afford excellent marks of distinction in discriminating the species; as from its situation, number, size, duration, &c. on the particular species, their difference is frequently more essentially distinguished.

The *Stipula* is in many plants very distinguishable and conspicuous, such as in rose, apricot, peach, cassia, tamarind tree, tulip-tree, bird-cherry, and all the papilionaceous or leguminous plants, and many others.

STOCKS, for Grafting and Budding.

Stocks, when alluding to the operation of grafting and budding, are young trees raised from seed, suckers, layers, and cuttings occasionally, designedly for the reception of grafts or buds of other trees, of any select or approved sort, to propagate and continue them the same without variation, by their uniting with the said young trees or Stocks, shoot out into branches, and become trees in all respects like the approved parent trees from which they were taken, and they thus remain supported and nourished by the trees on which they are grafted, commonly termed Stocks.

For as numerous trees, particularly the varieties of certain species, not continuing the same from seed, but often vary exceedingly to very different sorts, in order to continue them of the same approved varieties with certainty, recourse is had to propagating them by the operation of grafting or budding, being the insertion of shoots or buds of the said approved kinds of trees into the Stock or stem, or even the branches of other trees, which when intended for the purpose of grafting, &c. are always denominated Stocks, and should generally be species or varieties of the same genus as the trees with which they are to be grafted, or very nearly allied in their general characters, otherwise they will not grow upon one another: but the Stocks and grafts being of the same family, and the grafting and budding properly executed, the grafts, &c. unite firmly with the Stock, shoot and branch out into full heads, commencing trees in every respect like the select kinds from which the grafts or bud were cut, producing shoots, leaves, flowers, fruit, and seed, exactly the same as

the said parent trees; whether fruit-trees, forest trees, shrubs, &c. always retaining their respective properties distinct from the Stock, the Stock also continuing its inferior quality distinct from the graft, not interfering with the nature or quality of the trees grafted thereon; only supporting and nourishing them as effectually, as if upon their own roots; sometimes however, particular sorts of Stocks affect some varieties of trees, so far as to render them of longer or shorter duration; also in some sorts of trees improve or diminish the quality of the fruit: so that it is of consequence to be acquainted with the proper Stocks on which to graft or bud the different trees for general service, not only the trees of different genera, but also those of particular species, and varieties of each respective genus, as hinted hereafter in the general list of Stocks.

So that all trees, whether young or old, designed for grafting or budding upon, from the size of a large goose's quill, to one, two, or three inches in diameter, are distinguished by the appellation of Stocks; because the graft or bud is inserted into the stock or stem, sometimes occasionally into the branches, when intended to renew any old fruit-tree, or change the sort of fruit, or have two, three, or more sorts of flowers, fruit, &c. on the same tree; in all of which cases, the part receiving the graft or bud is styled the Stock.

Remarking, that Stocks for general use, may be used as such either for grafting or budding, when from the size of a good goose-quill, to half an inch, or not more than an inch thick in the part where the graft, &c. is to be inserted; likewise Stocks of two, or three inches or more diameter, either the stems or branches are also occasionally grafted or budded with success, not proper however for general practice; for the small young Stocks, of from two, to three or four years growth in the nursery, &c. and from about a quarter to half an inch thick, or but a little more or less in the part to be grafted, whether dwarf or standards, are generally the most successful for general grafting or budding in the nursery plantations, to raise any considerable quantity of trees for transplantation, either for private or public supply.

Observing likewise, Stocks for grafting and budding, are employed both for most kinds of fruit-trees, some varieties of forest and ornamental trees, and many of the shrub kind occasionally; as is generally exhibited in the culture of the respective sorts in the proper genera.

Remark also, that Stocks almost in general, when intended for grafting and budding, should be species or varieties of the same genus as the trees with which they are to be ingrafted; for most of the tree and shrub kind, whether fruit-trees, forest-trees, &c. succeed principally upon Stocks of their own family only, or such that are very near kindred by the *characters* of their flowers; their being but very few instances in which trees of different genera will grow by grafting or budding upon one another, except in some similar cases as follow; for example, the peach, nectarine, and almond being all of the genus *Amygdalus*, will take upon one another; and on Stocks of the *prunus* or plum, generally succeeding best upon that kind of Stock; that though of two distinct genera, are all icosandrious plants of the drupaceous stone-fruited tribe, nearly allied in their general *characters*; the same is also observable of the pear, which will take upon some species of the *Mespilus* and *Sorbus*, also on some of the species of *Crataegus*, such as white-thorn or haw-thorn Stocks; and all of those upon one another: but neither of these, nor the pear, however, are equally successful as upon Stocks of their own family; and even all the species of the same family do not succeed equally well upon one another, some sorts requiring Stocks principally of their own species, others those of some particular species or variety in the same genus.

For it being also remarkable, that although all the species of any particular genus grow by grafting or budding upon Stocks of one another, yet most sorts succeed best upon their own Stocks, except in a few instances; for example, the apple, pear, and quince being three distinct species all of the genus *Pyrus*, and will take upon Stocks of one another as above observed, but improper for general practice, as the apple always succeeds best upon its own species, i. e. any kind of apple or crab Stocks raised from the kernels of the fruit; the pear upon pear Stocks raised in the

same manner, and occasionally upon quince Stocks to form dwarf-trees; and the quince grows free enough on their own, or pear Stocks; again, the plum, cherry, and apricot, being all species of the genus *prunus*, and the grafts and buds of all three species will grow upon Stocks of one another, yet not all equally prosperous; for the cherry is always the most thriving upon cherry stocks, and plums and apricots best upon plum Stocks.

And in several instances some sorts are the most thriving on some particular variety of their respective favourite Stocks, exemplified in the peach and nectarine, which being generally more thriving and durable on plum Stocks than their own, yet on one particular variety of plum, namely the muscle-plum-Stock, they are generally the most prosperous and durable; the same is also observed of some other trees, both fruit and forest-tree kinds, as hereafter hinted in the list of Stocks.

Likewise, some sorts are the most prosperous on crab Stocks, others succeed well only on free Stocks, and some require dwarf Stocks, to dwarf them more or less, either for walls, espaliers, or forcing-frames, &c. See Crab Stocks, Free Stocks, &c. below described.

Of the different Kinds.

For the various kinds of Stocks may for distinction sake, be divided into three classes, agreeable to their different natures, viz. Crab Stocks, Free Stocks, and Dwarf Stocks; each of which comprehending various sorts, both of the same and different genera, species, and varieties; and those of each class, although they may prove species or varieties of the same genus, yet often assume different properties requisite to be known previous to their being grafted or budded, as described below each under its own head.

Crab Stocks.—The sort of Stocks generally considered as crabs, are all such that are raised from seeds, &c. of any wild ungrafted trees, particularly of the fruit-tree kind; such as the wild crab-apple of the woods and hedges, any kind of wild thorny uncultivated pears, plums, wild black and red cherry, and of such other trees as have not been grafted or budded; and as to the merit of these wild
Crab

Crab Stocks, some sorts being strong shooters and hardy, are preferred, on which to graft some particular species, as supposed to improve the size and duration of the trees; for example, apples are very commonly worked upon the common wild Crab Stock, and cherries on the great wild black and red cherry Stock, as tending to promote a large, hardy, and durable growth proper for common standards, and the larger kinds of dwarf trees; remarking however, in using Crab Stocks for general use, on which to graft any sorts of fruit-trees, it is proper to reject such of them as assume a very wild crab-like growth, or of a stumpy, thorny nature, preferring those that are the freest clean growers.

However, the appellation of Crab Stocks, is also often given to all Stocks indiscriminately, before being grafted; whether raised from the seed, &c. of wild or cultivated trees, being very commonly all denominated crabs until worked with grafts or buds; though probably with some distinction, as wild crabs, and free crabs.

Free Stocks.—The name Free Stocks is commonly applied to such as are raised from the kernels of the fruit, layers, &c. of any of the cultivated garden and orchard fruit-trees and others, which as they often prove in general more free clean shooters than the generality of wild crabs, have the appellation of Free Stocks, and in several instances when proving free clean growers, are more eligible Stocks than the wild crabs, particularly for choice pears, peaches, nectarines, apricots, and plums, both to improve the growth of the trees and quality of the fruit, as is observed below in the List of Stocks, and in the culture of the respective sorts under their proper head; observing however, that as also in these seedling Free Stocks, some may appear of a wild crab-like growth, or of a stumpy thorny nature, as aforesaid; which, when the real Free Stock is intended, should be all eradicated, reserving only the free clean shooters of a cultivated-like growth for grafting and budding.

But as we noticed above of the crab Stocks, all Stocks raised from seed particularly, both of the wild, and cultivated garden fruits, are before they are worked very commonly termed crabs; either wild crabs or free crabs, as before observed, and with some

propriety; since all seedling Stocks though raised from the finest fruit, vary so greatly from the original, many of them often assuming a wild crab-like growth, and if permitted to stand long enough without grafting to bear, it is probable the fruit would prove also of the crab nature, intolerably hard and austere; hence the necessity of grafting and budding: but on the other hand, many of them assume a free, cultivated-like growth, and if trained up without grafting to a bearing state, some out of a great many may produce tolerable good fruit, though probably not above one or two, in a hundred or more; which however, is the method by which all our fine varieties of fruit were first obtained, and the sorts afterwards encreased and continued the same by grafting and budding them upon proper Stocks; so that for experiment, might select a few of the most promising of any of these seedling Free Stocks if thought convenient, transplanting them by themselves, to try to gain new varieties; but allotting however, the general supply to remain for Stocks, for the reception of grafts and buds of the choicer kinds of the already-acquired fruits for farther propagation.

Dwarf Stocks.—These are raised from low-growing trees, some nearly of a shrub-like nature, and others of but a very moderate tree-growth, being occasionally employed as Stocks on which to graft and bud trees, intended as the lower and middling sorts of dwarfs, either for walls or espaliers, or as dwarf standards in small gardens, and to plant in forcing-frames, or to pot for forcing, or curiosity, &c. such for instance, the paradise apple and codlin Stock for dwarfing apples, the quince Stock for pears, the bird-cherry and morello cherry Stock for cherries, the black bullace and muscle Stock for dwarfing apricots, dwarf almond for peaches and nectarines, when designed to have these trees of a very dwarfish growth, either to pot for curiosity, or for forcing in small forcing-frames.

Observing, the most dwarfish kinds of Stocks of the above are, the paradise Stock, bird-cherry, black bullace, and dwarf almond; all of which being of very moderate growth, when used as Stocks, they dwarf the trees grafted thereon exceedingly, the head remaining within very small compass, and shooting moderately into wood, soon forms for bearing abundantly in proportion.

portion to their size; they however are not proper for any general use as common dwarf-trees, as they never attain a due size sufficient to produce any considerable quantity of fruit, and are rarely of long duration; so that a few only are proper for variety, or for very small gardens, or to pot, or for forcing as aforesaid.

But as to the codlin dwarf Stocks, quince Stock, morello cherry, and musclem-plum Stocks, they being but moderately dwarf, are proper Stocks for the middling, or larger kinds of dwarf trees, either for walls or espaliers, or dwarf standards.

All of which dwarf Stocks both of the most dwarfish growers, and middling growth, are generally raised either from suckers, layers, and cuttings, as hereafter directed.

But we now proceed to exhibit the list of all the principal sorts of Stocks comprehended in the above three kinds; crab Stocks, free Stocks, and dwarf Stocks, under the names of the respective genus, species, &c. in which they are used for grafting and budding.

List of the various Sorts.

As it is therefore of importance to know all the different sorts of Stocks eligibly adapted for the reception of grafts and buds of the various genera, species, and varieties of trees usually propagated by grafting and budding; particularly, all the fruit-tree kinds, and some others, we will exhibit under this head a list of all the principal sorts in general use, arranging them separately under the name of the species or variety to which each sort is peculiarly adapted as Stocks, for the reception of their respective grafts and buds.

For apples (*Pyrus malus*).

The Stocks for all kinds of apples, are their own kind, raised from the kernels of any of the cultivated apples or crab for common standards, and the larger kinds of dwarfs; though the wild crab Stock is often esteemed preferable to the free Stock for its hardy and durable nature, on which to graft common standards, and dwarfs for espaliers, as being supposed to render them of more hardy growth and longer duration; and for lower dwarfs, the codlin and paradise Stock are occasionally used; the former for middling dwarfs, and the latter for the smallest dwarfs, when required for small gardens, &c.

All these Stocks for apples are easily raised, the free Stock and crabs from the kernels of the fruit, and the codlin and paradise Stock from suckers, layers, and cuttings. See *PYRUS MALUS*.

For the pear, (*Pyrus Communis*).

The pear-tree is grafted and budded principally on pear Stocks for general use, and occasionally on quince Stocks for dwarfs; raised, the former chiefly from the kernels of any sort of pears; and the latter freely by suckers, layers, and cuttings.

Though the pear Stock is always to be preferred for the general supply; raised from the kernels of the best summer and early autumn pears, being the most eligible Stock on which to graft or bud for all common Standards, and the larger dwarf pears for high walls and espaliers.

But to raise either standards or dwarfs of a more moderate growth, they are occasionally worked on quince Stocks, generally raised from suckers, layers, or cuttings as aforesaid; for the quince-trees being low moderate growers, when used as Stocks for any kind of pears, they dwarf the trees pretty considerably, rendering them more proper for small gardens, and for low walls and espaliers, or dwarf standards; and the trees often commence a bearing state sooner than on strong-growing pear Stocks: remarking however, this sort of Stock is in more estimation for the melting pears, than the hard breaking kinds, being supposed to improve the fruit of the former, and render the latter stony; but the quince Stock at any rate, unless growing on a strong moist soil, rarely furnish such prosperous pear-trees as the pear Stock, nor prove of so long duration.

Sometimes, also to form dwarf pears, white-thorn Stocks, raised from seed, were formerly in repute, but are very improper, as they have a bad effect in rendering the fruit small and hard, and the trees are rarely prosperous for any long duration.

Therefore the pear Stock is greatly preferable to use for grafting or budding all the sorts of pears for the general supply; observing however, as the goodness of a pear is often improved or diminished by the nature of the Stock on which it is grafted, so it is of importance to use principally free Stocks raised from the kernels of the best summer and autumn pears, and being raised, if any
among

among them assume a wild crab-like appearance, reject them, especially for the prime pears, which should be worked always on the finest free-shooting Stocks of the most cultivated-like growth.

And sometimes to improve the quality of any particular choice kind of pears as much as possible, some double work them, i. e. graft the best sorts into free Stocks in the spring, which shooting the same year, then about midsummer or soon after, bud the young shoots of the graft with buds of the prime sorts of pear, suffering only the shoots from the budding to run up to form the tree: thus the breaking kind of pears are often rendered less hard and stony, and the melting property of others considerably improved; but this double working is not intended for general propagation.

Both the sorts of Stocks for pears are easily raised by the methods above noticed, and as hereafter directed.—See *PYRUS Communis*.

For quinces (*Pyrus Cydonia*.)

Two sorts of Stocks are occasionally used for this tree, viz. that of its own kind, and the pear Stock raised, the quince Stocks from suckers and cuttings, &c. and the pear kinds from the kernels of any sort of pears: but as all the varieties of quinces are so expeditiously raised the same with certainty by layers and cuttings, renders the raising of Stocks for grafting or budding them on, almost unnecessary. See *PYRUS Cydonia*.

For plums (*Prunus domestica*.)

This tree is worked only upon plum Stocks, raised from the stones of any sort of cultivated plum, and by suckers and layers thereof; as plums propagate also freely by these methods, and are certain methods of propagation to obtain any particular variety of free plum Stock when required; such for instance, as the muscle-plum Stock, which many prefer as the best Stock of all on which to work the finer kinds of plums, as generally producing very thriving and durable trees, raising it, not from seed which would vary exceedingly, but principally by suckers from the root of real muscle plum-trees, or of those worked upon the true muscle Stock; or from layers also of the muscle-plum tree: observe however, plums almost in general succeed equally well on any kind of free plum Stock; and therefore, the general supply may be raised from any sort

of plum, either by seed or suckers, &c. as may be convenient; as directed hereafter.

The plum will also grow upon the apricot and cherry Stock, but not thrivingly for any great duration.—See *PRUNUS domestica*.

For cherries (*Prunus Cerasus*.)

The proper Stock for this tree, is that of the cherry kind only; viz. the great wild cherry Stock for large trees, the cultivated garden cherries for more moderate growths, and the bird cherry Stock for small dwarfs; raised, the two former from the stones of the fruit, and the latter also by seed, or by layers and cuttings.

But as for general use, the wild black and red cherry Stocks, being strong free growers, are preferable, on which to raise all common large standard cherries particularly; also the larger dwarf-trees for high walls and espaliers; as these Stocks being of strong hardy growth, generally produce larger, more hardy, and durable trees than the cultivated cherry Stocks; though in default of these wild Stocks, may use Stocks raised from any of the cultivated garden cherries, to raise moderate standards and smaller dwarf-trees; it is however of importance to raise the general supply of large trees on the wild cherry Stock, for the reasons abovementioned.

Sometimes Stocks of the morello cherry, as being but a moderate grower are used, on which to raise the smaller dwarf cherry-trees for low walls and espaliers, or moderate standards, for small gardens, &c. but remarking of the morello Stock, that if raised from layers you will be more certain of having the real sort in its naturally moderate growth.

And Stocks of the common bird-cherry (*Prunus pudus*), being the lowest grower of the cherry kind, is used, on which to raise very dwarf cherry-trees, either to plant in forcing frames, or to pot for forcing, &c. are raised plentifully from cuttings, and have the effect of dwarfing trees worked thereon exceedingly, so as to bear fruit when but one or two feet high; and they shooting very little to wood, generally bear abundantly for their size.

Cherries will also grow upon plum, apricot, and laurel Stocks as being all of the same genus, but not proper for general propagation, only by way of curiosity or experiment.

All the varieties of cherry Stocks are raised with great facility by the methods

above hinted and hereafter exhibited.—See *PRUNUS Cerasus*.

For apricots (*Prunus Armeniaca*.)

The apricot proves the most durable on Stocks of the plum kind only, viz. common plum Stocks of any variety for all common wall, espalier, and standard trees; and the black-bullace Stock for small dwarfs; raised, the plum Stocks from the stones of any kind of cultivated plum, or by suckers from the root; and the bullace from seed, suckers, and layers.

But always chuse the plum Stock on which to raise the general supply of apricots for common use, which succeed almost equally well upon Stocks of any kind of plum, though they probably may prove the most successful on the muscle-plum Stock, like peaches, &c. but as no great difference is discovered, we may use any kind of plum Stocks that can be the most readily obtained, on which to raise all our principal apricot-trees, for walls, espaliers, and standards.

And the bullace Stock is only used occasionally on which to raise very small dwarfs for low walls, or to plant in pots, or in forcing frames for forcing.

Note, the apricot will grow on its own, and on peach and almond Stocks raised from the stones, but never so prosperous for any duration.—See *PRUNUS Armeniaca*.

For peaches (*Amygdalus Persica*.)

Several sorts of Stocks are occasionally used for peaches; viz. almond Stocks, peach, nectarine, apricot, and plum Stocks, all raised from the stones of the fruit, and the latter also by suckers and layers; but the plum Stock being the most hardy, is the most eligible for general use.

For the peach is not equally successful and durable on all those kinds of Stocks; on those of the almond, peach, nectarine, and apricot, although they take freely, shoot fair and promising for some years, yet are frequently apt to gum exceedingly, and prove but of middling duration; so that the free plum Stock is preferable for all the sorts of peaches and nectarines, as being productive of the most hardy, thriving, and durable trees; though it is remarkable, one sort of plum Stock in particular, is generally preferable to all the others on which to work peaches, as producing the most prosperous trees, and improving the fruit; which is that of the muscle-plum, formerly hinted, if raised genuine; not from the stones, for,

as observed before, the seedlings run into many varieties very different from the original; but should be raised real, from suckers or layers of the true muscle-plum-tree, or by suckers from the roots of such old peach, nectarine, plum, &c. as are worked on muscle-plum Stocks, which generally send up plenty from the roots annually; planting them off at one year's growth into the nursery to train for use: however, for want of a sufficiency of this approved Stock, recourse must be had either to seedling Stocks raised from the stones of the muscle or any other kind of plum, or suckers, or layer Stocks of any of the plum varieties; but always giving preference to the true muscle-plum Stock where it can be obtained.

Double Stocks or double working, is sometimes used for the more delicate peaches, to improve their bearing and flavour of the fruit; and consists of first budding in the common way, by inserting buds of any strong shooting peach, almond, or apricot into a plum Stock; and the buds shooting out strongly next summer, then upon the main shoot from the bud, perform the second or final inoculation with buds of the approved sort intended for propagation, suffering the shoots from the second budding only to grow up and form the tree; and by this practice the delicate flavour of some sorts of peach fruit is more certainly preserved, and sometimes improved.

For nectarines (*Amygdalus Nucipersica*.)

The nectarine is worked upon the same Stocks as the peach, viz. almond, peach, nectarine, apricot, and plum; all raised as observed above for the peach-tree: preferring however, the plum Stock for general propagation, and if the true muscle-plum Stock, as for peaches, it may improve the prosperity of the trees.—See the Stocks for peach trees above.

For almond-trees (*Amygdalus communis*.)

The almond-tree when raised for its fruit, the approved varieties may be budded into Stocks of any sort of almond, peach, nectarine, apricot, or plum, raised from the stones, and the latter also from suckers, &c. but the trees are generally the most hardy and durable on plum Stocks.

For medlars (*Mespilus Germanica*.)

About three or four different Stocks are occasionally used, on which to raise the approved varieties of eatable medlars, viz. medlar Stocks, white-thorn, pear, and quince Stocks,

Stocks, raised, the three former from seed, and the latter expeditiously from suckers, layers, and cuttings; the white-thorn Stock is very commonly used for these trees, but free pear Stocks raised from the kernels of good summer or autumn pears are rather preferable for all the varieties of common medlar, which on these Stocks generally assume a more free growth, and produce the fruit in greater perfection.

For sweet Service-trees (*Sorbus domestica*.)

The household or sweet service when designed as a fruit-tree, have the approved varieties grafted or budded upon proper Stocks; either their own Stocks raised from the seed, or on pear or quince Stocks raised as mentioned just above for medlar and other trees; though the pear Stock is preferable to the quince on which to work this tree to have it large and durable.

For the wild maple-leaved Service berry-trees (*Crataegus torminalis*.)

This tree being sometimes cultivated in the garden and orchard for its eatable berries; and to obtain or continue any particular good variety with certainty, they are occasionally raised by grafting or budding, and the proper Stocks are either their own kind, or hawthorn Stocks, raised from the seed; they will also take upon pear Stocks, &c.

For hazel nuts, filbert nut, &c. (*Corylus avellana*).

Any approved variety may be continued the same with certainty, by grafting and budding upon Stocks of the common nut-tree, raised from the nuts or suckers from the root; though as all the varieties may be readily encreased, and continued the same by layers, &c. with great facility and abundance, the grafting or budding is not commonly practised in their propagation, only in particular cases, in default of layers or suckers of any particular good sort of nut, and that cuttings or buds for grafting or budding, can be more readily obtained from neighbouring trees of the sorts intended; and having raised a few trees by this method, they in two or three years furnishing plenty of branches to raise a more plentiful supply by layers; and these layer-raised trees, being wholly the same top and root, suckers from the bottom are equally eligible as grafting and laying, for continuing any approved variety.—See *CORYLUS avellana*.

For orange-trees (*Citrus Aurantium*.)

The orange-tree is worked upon Stocks of

their own kind only, viz. either any kind of orange, lemon, or citron Stocks, raised from the kernels of the fruit; though of the orange kinds, the Seville orange, as being a very free strong shooter, is generally preferred for orange Stocks; but the lemon and citron being also free growers form very proper Stocks on which to raise any variety of orange. See *CITRUS Aurantium*.

For lemon and citron trees (*Citrus Medica*.)

Both these varieties are also budded or inarched upon lemon, citron, or orange Stocks, raised from the kernels of the fruit, as observed above for oranges. See *CITRUS Medica*.

Thus far is principally all the sorts of Stocks commonly used for fruit-trees, that are either generally, or occasionally raised by grafting and budding.

For the several other sorts of fruit-trees, not mentioned in the above list of Stocks, such as the vine, fig, mulberry, currant, gooseberry, barberry, walnut, chesnut, &c. in their several varieties, being, in the first six sorts particularly, raised and continued the same with greater facility by layers, suckers, and cuttings, which renders the propagation by grafting and budding unnecessary; and the walnut and chesnut not succeeding perfectly by these methods to become large thriving trees, are raised from the nuts: however, any approved variety of most of the above-mentioned sorts, may also be tried occasionally by grafting and budding upon proper Stocks by way of experiment; and the eligible Stocks are principally those of their own kind, raised some from suckers, layers, and cuttings; others also from seed, as exhibited in the culture of the respective sorts, under their proper genera.

For forest and ornamental trees, flowering shrubs, &c.

As to the Stocks proper for such forest-trees, ornamental trees, and flowering shrubs, &c. that are occasionally raised by grafting and budding, either to improve or continue any particular variety, they are for the general part each worked on Stocks of its own kind, as observed above for the generality of fruit-trees; but as in these kind of trees, the variation of the seedlings being not so numerous and material as in the fruit-tree kind, they do not require to be so generally raised by grafting or budding, only for some particularly valuable variety, or any of peculiar property, such as variegated, or other remarkable leaved kinds, double-

flowering variety, or other curious flowering sorts, &c. that cannot be continued the same by seed, but only either by grafting or budding, or by layers and cuttings; though as the two latter methods are not convenient in all sorts, recourse is had to grafting and budding to encrease the above varieties with certainty of the kinds intended, without farther variation: working the respective sorts principally each upon Stocks of its own kind, chusing the strongest free shooters, raised either from seed or suckers, &c. as mentioned in their culture, each sort under its proper genus as observed on former occasions.

General Hints for Experiment.

Sometimes for variety and curiosity in any sort of fruit-trees and others, the same Stock is made to support two, three, or more different varieties of fruit, grafted or budded, either all into the Stock, being previously trained with branches forking off for that purpose one for each graft, or by cleft, or crown-grafting single large Stocks with two or more different sorts; or in smaller single Stocks by inserting two or more different buds; likewise any Stock being singly grafted or budded, may insert different sorts into the shoots arising from the said graft, or buds; and thus may have two, three, or more sorts of apples, on the same root for curiosity; the same of pears, plums, cherries, and most other fruits, &c. that are chiefly species or varieties of the respective sorts in the same genus, or that which is very nearly allied, as we have already exhibited; and in several instances, by the same rule and method, may have different sorts of fruit upon the same Stock, as plum, cherries, and apricots all on a plum Stock, or peaches, nectarines, and apricots on the same, or on Stocks of their own kind; and pear, medlars, and quinces upon the pear Stock; also red and white currants, or currants and gooseberries, both on a currant or gooseberry Stock; or white and red grapes on any vine Stock: likewise red and white roses, or other different sorts, upon any common rose Stock; and the same of numerous other trees and shrubs, species and varieties of one genus; remarking however, this is not recommended for any general practice, but only for a tree or two of any particular genus or species, by way of experiment, variety, and curiosity.

Method of raising the Stocks in general.

With respect to the method of raising all the different sorts of Stocks, it is occasionally by seed, layers, suckers and cuttings, as hinted above in the list for each particular sort.

By Seed. — Numerous sorts of Stocks are easily raised from seed, consisting of the kernels and stones of the fruit, of the respective trees, such as the kernels of the crab-apple, and all the other apple kinds; kernels of all the sorts of pears; and the stones of plums, cherries, apricots, peaches, nectarines; the seeds or stones of medlars, services, haws, &c. when designed for Stocks; all of which are to be obtained in autumn from their respective fruits when fully ripened; previously laying the larger fruits together in an heap, and bruise them; suffering them to lie some time to decay as the different sorts may require, in order that the pulp may be more readily cleared from the kernels and stones proper for sowing; or, the kernels of apples and pears may also be procured from any of the accidentally rotten fruits in the fruitery; and sometimes both apple, pear, and crab kernels are occasionally obtained from the cyder presses after the fruit have been pressed for cyder, perry, verjuice, &c. but the stones of plums, cherries, apricots, and the like must be procured from the fruits as above, as soon as they are ripe; which together with all the other sorts, may be sowed as soon as possible, each sort separate.

All the sorts, both kernels, stones and other seeds, are to be sowed in beds of common earth in the nursery, either directly in autumn, or preserved in sand till February, and then sowed.

Observing however, that for the general part, it is eligible to sow them principally in autumn or early part of winter, as October, November, or December, unless the ground proves of such a wet cold nature, as to endanger their rotting in winter; and that it shall seem necessary to preserve them in sand in a dry apartment until February, as before observed.

However, in any common moderately dry soil, it is adviseable to sow them at once in autumn, or as soon as they can be obtained, as it will be both less trouble, and may prove more successful in forwarding their

their germination; and if the winter should prove severe, the beds of the more tender kinds, as almonds, and peaches, &c. may be covered with dry litter to defend the seed from the frost.

The method of sowing all the sorts is in beds of any common light earth in the open nursery or seminary, sowed either by bedding in, or in drills, as below. — See NURSERY.

Having however previously digged the ground, then if intended to bed in the seeds, divide the ground into four-feet-wide beds, with foot-wide alleys between; and then with a rake or spade trim the earth from off the top of the beds evenly, into the alleys from about an inch, to an inch and half, or two or three inches deep, according to the size of the different seeds; this done, sow the seeds all over the surface moderately thick, and after pressing them all evenly down into the earth with the back of the spade, cover them in with the earth from the alleys evenly, the depth as above; the kernels of apples, crabs, pears, &c. near an inch deep, the smaller stones about an inch and a half, and the larger sorts full two inches deep. But if it is designed to sow them in drills proceed thus, having digged the ground, and formed it into four-feet-wide beds as above advised, then draw drills with an hoe, either lengthways or cross the bed, from one to two or three inches deep, and six inches asunder at least, sowing the seeds, &c. in the drills, and directly cover them in with the earth the depth of the drills. — See SOWING of SEED.

After having performed the sowings as above, if the ground is much infested with mice or other destructive animals which often attack these kind of seeds in winter, it is adviseable to set different sorts of traps and baits, for their destruction.

The different seeds being thus sowed, they will all germinate freely in the spring, and soon come up the same season; observing previous to the sprouting or appearance of the seedlings above ground, that if the surface of the bed proves mossy, or that the top is hard bound or caked, it is beneficial culture to stir the surface lightly with a small iron rake, also if harsh dry weather prevails, to give frequent moderate waterings both before and after the plants are up; repeating the waterings occasionally in dry wea-

ther all spring and early part of summer, to encourage a free strong growth; being likewise careful to keep the beds very clean from weeds by diligent hand weedings; and by thus giving every encouragement of culture, the seedling Stocks will grow so freely all summer, as by autumn or spring following, will be mostly of proper size to plant out into nursery-lines in the open quarters, in rows two feet asunder, to remain for grafting and budding; though if they have made but middling progress this first summer in the seed-bed, and are rather small and weakly, may plant out only the strongest, leaving the rest growing until next autumn, when they will be all of full size for planting out wholly into the nursery quarters.

Therefore when the Stocks are of due size for removal from the seed-bed, chuse for their reception some of the open quarters of the nursery, preparing the ground by trenching two moderate spades deep; then forking the seedlings up out of the seed-bed, shorten any perpendicular tap-root and long stragglers, but leave all their tops entire, and then proceed to plant them in lines, either by trench-planting, slit planting, or dibble-planting, as the size of the plants admit (see PLANTING), marking out the rows two feet asunder, and set the plants one foot or fifteen inches apart in each row, all in an upright position; and having planted one row, then tread the earth gently all along close to the roots of the plants, to fix them firmly in the earth all evenly in a strait range and erect posture; and so proceed row and row till all is planted, leveling the surface of the ground between all the rows with your spades.

As to their future culture till grafted or budded, it consists in occasional waterings the first spring, hoeing the ground every summer to kill weeds; digging between the rows annually in winter or spring; and of training the Stocks each to one stem, preserving their top always entire; but trimming off strong laterals below, to encourage the strength of the main stem, and the aspiring of the top as fast as possible; whereby they will be fit for grafting or budding in, from one to two or three years after planting.

They are generally of proper size for working, when from about the size of a large goose-

goose-quill already observed, to the thickness of a man's little finger or a little more; but the sooner they are worked after having obtained due size, the better they will succeed, and the sooner you will have them form trees of the sorts intended. — See **GRAFTING** and **INOCULATION**.

But supposing the Stocks to have shot freely the first summer after planting out from the seed-bed, many of them will probably be of due size to graft the following spring and summer, at five or six inches height, to form dwarfs for walls and espaliers, &c. or even in some sorts, for full or half Standards; provided the first main shoot from the graft or bud is trained up singly, two or three years to form the stem, or from four or five, to six or seven feet stature: however, if the Stocks have growed but moderately the first season, and that they are not generally in a condition for the operation of grafting or budding, let them have another year's growth, or till arrived to the before-mentioned size, which may be sufficient for dwarf-trees; also occasionally for standards, when the graft or bud is to form the stem, as above observed; but when designed for standards, and the Stock to form the stem, they must be permitted to stand two or three years longer, trimming off strong shoots below, and still preserving the leading top shoot entire to continue the elongation of the stem to an eligible stature, to receive the graft or bud at five or six feet height for full standards, and three or four for half standards; so that these standard Stocks being arrived to about seven feet height for full, and five or six feet for half standards, and of the before-mentioned thickness at top, in the place where the graft or bud is to be inserted, they are of due size for working.

By Suckers.—Several sorts of fruit and forest-trees, &c. furnish many suckers from the root annually, very proper to be transplanted for Stocks; such for instance, as codlins, plums, and quinces; also peach, nectarine, and apricots on plum Stocks, pears on quince Stocks, any sort of apples on codlin Stocks; likewise most sorts of elms, and many other forest and ornamental kinds. And the suckers of all these trees being planted off at one year's growth in autumn or winter, is a very expeditious and eligible method of raising several sorts of Stocks;

as that after being transplanted into the nursery, they often in one year commence proper Stocks for the reception of grafts and buds; and sometimes many of them will be fit for budding in the summer following at the proper budding season, or for grafting the spring after.

Likewise in some instances, suckers afford an opportunity of raising Stocks of any particular variety required with certainty, such as the muscle-plum for peach Stocks, codlin for dwarf apples, and the like particular kinds; for when the trees productive of the suckers are either wholly top and root of the variety intended, or that they form Stocks to other trees, the Stock and root still remaining of the intended sort: and in either case, all the suckers prove invariably the same as the parent-tree; but this is only to be particularly regarded when any particular variety of Stock is required; in other cases may use suckers of all other fruit-trees, &c. indifferently for Stocks.

They are generally fit to take up for the purpose of Stocks when of one year's growth, about the size of a tobacco-pipe or but little bigger, and should be collected in autumn or early part of winter; taking them up as well rooted as possible, cutting off all knots or knobbed woody parts of the old roots that may adhere to their bottom, trim straggling fibres, and cut off all side-shoots from the stem, then plant them in rows two feet asunder, and one foot distant in the lines; treading the mould gently to their roots, and finish the work by levelling the surface between the rows: thus they will readily take root, and in spring soon shew signs of free growth.

Then as to culture till grafted or budded, it is nearly the same as the seedling Stocks, keeping them clean from weeds in summer by hoeing; and probably some of the strongest shooters may be fit to bud in July or August following; though the general part will require two years growth before they are proper for working, still continuing them all to one stem, by timely displacing strong laterals; and preserve their top or leading shoot generally entire until grafted, &c. which may be performed when they are of the sizes before mentioned.

By Layers.—Some sort of Stocks, both of fruit and other trees, may also be raised occasionally by layers; and when any particular

particular variety of Stock is required, such as the paradise Stock for apples, musclem-plum for peaches, &c. they may be obtained of the real sort always with certainty, by layers of the shoots of such trees as are wholly of the intended sort; but as this method of raising Stocks would be attended with great trouble for general grafting and budding, it is only practised occasionally when a sufficiency of any particular sort of Stock intended, cannot be obtained by suckers, &c. so that in autumn or winter, chusing the young shoots either of such trees whose branches naturally grow near the ground, or have been cut down low while young, to force out branches near the bottom, furnishing shoots properly situated for laying; which being slit-layed in the common method, they will be rooted by autumn following, and fit to plant into the nursery; managing them as directed for the seedling and sucker Stocks.

By Cuttings.—As some sorts of trees proper for Stocks, grow freely by cuttings; such as codlins, quinces, bird-cherry, paradise Stock, &c. a supply of Stocks of these sorts are sometimes raised by this method; chusing cuttings of the year's shoots in autumn, plant them in the nursery in a somewhat shady border, giving occasional waterings the following spring and beginning of summer in dry weather, and they will be well rooted by next autumn, then transplanted in nursery-rows two feet asunder, managing them as the others.

Remarking of the Stocks in general, raised in either or by all the above methods; that as we formerly observed they must always be continued to one upright stem, with their top entire; except any should assume a stunted or crooked growth, in which case, head them down to the ground in spring, they will push out strong from the bottom the ensuing summer, training them to one stem, and with their leading top-shoot entire as abovesaid; and according as all the sorts advance in growth, divest them of strong lateral shoots below, repeating it particularly in the taller standard Stocks to encourage their upright direction more expeditiously to the proper grafting and budding height.

With respect to the different methods of grafting and budding the several sorts and sizes of Stocks, the grafting them is occa-

sionally performed different ways according to the size of the Stock; and the budding them is performed only by one method to all sorts; remarking as to grafting, the method called whip-grafting is considerably the most eligible for general practice, and is always performed upon small Stocks: likewise budding is also the most successfully performed upon small or moderate sized Stocks; for example, young Stocks from the size of a large goosequill, to the thickness of the little finger, in the part where the graft or bud is to be inserted, are of the most eligible size for general working; for all nursery Stocks, performed either by whip-grafting, or by inoculation as the different trees may require: though cleft-grafting is also occasionally performed on small Stocks, but not so successfully as whip-grafting, so is more commonly practised for such Stocks as are too large for that method of grafting; but large Stocks of an inch or more diameter, succeed very well by cleft grafting; also sometimes tolerably by budding, but not in general so effectually as smaller Stocks, &c. above mentioned. And such Stocks as have stood to grow very large, perhaps two or three inches or more in diameter, may also be grafted occasionally with tolerable success, but do not succeed by inoculation: and crown-grafting is generally the best method for such large Stocks; sometimes also cleft-grafting is practised by making several clefts round the top of the Stock, and insert one graft in each, though the working of these very large Stocks is the most generally, and successfully practised when they are growing in the places where they are finally to remain; but for the methods of performing the operations of grafting and budding the various sorts of Stocks for raising the several kinds of dwarf and standard trees, see GRAFTING and INOCULATION; also the several sorts of trees raised by these methods, as apples, pears, plums, peaches, &c. each in its respective genus.—Also DWARF TREES, STANDARD TREES, WALL and ESPALIER TREES.

After grafting and budding the several sorts of Stocks, they may be then said to commence trees of the name of the respective sorts with which they are worked, especially after the graft and bud begins to shoot, which growing up into branches, forms the new tree of the sort intended.

STOOLS,

STOOLS, to furnish layers.

Stools are headed-down trees and shrubs in the nursery, appropriated for the production of an annual supply of lower shoots or branches near the ground, eligibly situated for effecting the propagation of the respective sorts by layers. See LAYING.

Such trees and shrubs as are designed for Stools to furnish layers for the work of propagation, are generally headed down to the bottom in the nursery, &c. in order to force out more effectually a plenteous supply of branches near the ground, to afford layers conveniently situated for laying down in the earth as aforesaid; which being layed in autumn, winter, or spring, they striking root in a year or two; and each layer commencing a distinct plant, are planted off into the nursery in autumn following; the Stools remaining, send out a farther supply of lower shoots the following summer for laying as before; and thus the remaining Stools continue affording a plentiful supply of branches from the bottom, fit for laying annually, or every other year at least; and hereby propagate the sorts intended with great facility and abundance.

Therefore, as many sorts of trees and shrubs are with great facility propagated by layers, a sufficient number of the respective sorts in the nursery, &c. should be appropriated for Stools, in proportion to the supply required of the sorts intended, whether in the public nurseries for sale or for private plantations; chusing for this purpose some strong young trees and shrubs, which being planted in the nursery, &c. at from five or six, to eight or ten feet distance, according to their size or nature of growth, and after having remained a year or two till firmly rooted, and acquired some substance, then all those of the tree kind, or such others as run up with tall stems without affording lower branches near the ground for laying, should in autumn, winter, or early in spring, be headed down within a few inches of the ground; by which operation they in summer following will push out from the bottom plenty of strong young shoots commodiously placed near the ground for laying, which may be performed the succeeding autumn or winter, or if you wait till the second autumn, the first shoots sending out many lateral or side shoots the ensuing summer, and thereby probably furnish five or ten

times more shoots for laying; and these small laterals are often better adapted for rooting, than the first vigorous shoots that rise immediately from the stool, and each of which layed will form a new plant; however you will order this as it shall seem convenient, as some sorts may afford a sufficiency for laying the autumn after they are produced; others may require to grow till the second or third autumn before they are eligible for laying.

As to the method of performing the operation of laying, it being fully explained in all the various ways in practice under its proper head, we will not repeat it here, so refer the reader to the article LAYING.

In most sort of Stools where the laying is performed in autumn, or early in winter, the layers are for the general part well rooted in one year, commencing proper plants fit for separation from the Stools in the autumn following, in order for planting out in nursery rows to be trained for the purpose intended; though some very hard-wooded sorts require two summers growth in the layer-bed before they are sufficiently rooted; on the other hand, some sorts being laid in summer in the young shoots of the year, often effect their rooting freely the same season, fit for planting off the following October.

However, in all sorts it is proper to examine the layers in the autumn after they are layed; and all those sorts that are rooted should then be taken off, separating them with a knife from the Stools, with as much root as possible; and directly planted in nursery-rows a foot or two asunder; and the more tender sorts plant in pots for moving under shelter in winter, as directed for each sort under its respective genus; then when the layers are all thus planted off, let the remaining Stools be trimmed and dressed as below, for providing a fresh supply of layers the succeeding year.

Every year soon after the layers are separated from the Stools, the latter should be dressed, which consists of trimming the head by cutting off all parts of old branches and scraggy stumps within an inch or two of the main Stool; and then dig and level the ground neatly about and between the whole, and in spring and summer, give occasional hoeings in dry weather to destroy weeds; thus repeating the same work of trimming,

trimming, digging, and hoeing every year; and the Stools still remaining, supply you with plenty of layers for years to come.

But sometimes Stools for layers are formed occasionally of trees, &c. that are considerably grown up, not having been headed down to form low Stools, but whose branches are of some considerable height from the ground; and in which case, the branches, if flexible and long enough, are bowed down to the earth; or if inflexible and too stubborn to bend, are splashed by making a gash or cut on the upper side; or if too large for splashing, or that the nature of the wood will not bear that operation, they are thrown on their sides by opening the earth about the roots, loosening or cutting those on one side to admit of lowering the head sufficiently for laying the branches in the ground.

Sometimes also Stools being formed of grown-up trees, whose branches are too high for laying in the full ground, a temporary stage or scaffold is erected on which to place pots or tubs of earth for the reception of the layers.—See LAYING.

STOVE, or Hot-house.

Stoves in gardens are ranges of buildings constructed with brick walling behind on the north, and fronted and roofed wholly with glass sashes next the south, full upon the sun; furnished internally with a pit or long, wide, and deep cavity for a bark hot-bed; and with flues round the inside of the walls for fires: the whole calculated to produce a certain temperature of heat at all seasons, peculiarly adapted to the culture of the tenderest exotic plants from the hot parts of the world; also for forcing various plants, both hardy and tender, into flower and fruit, &c. at an early season.

Formerly, before the use of bark-beds was introduced, all Stoves or Hot-houses were worked by fire heat only, hence they obtained the name of Stoves.

These Stove departments are generally constructed in an oblong manner, ranging in a straight line lengthways nearly east and west, with the glass front, and top, full upon the south sun, or inclining a little to the south-east; and in dimensions, may be from fifteen or twenty, to fifty or an hundred feet long; by twelve or fourteen, to sixteen feet wide or more in the clear, and from ten to fourteen feet height commonly in the back wall, by five or six in front, including the wall, and upright

glass-work together; and with the whole roof over-head sloping to the south entirely of glass-work, supported on proper cross bearers.

Observing however, as to its general structure, a wall of brick-work is first formed all round, raised behind from ten to twelve, or fourteen feet height, as just observed; and only two or three feet in the front and both ends, on which to support the glass-work; previously forming the furnace or fire-place of the flues near the foundation of the back wall outward, at one or both ends according to the length of the building, or may be in the back part of the end walls; the flues, for conducting the fire-heat, to be ranged internally close along the inside of the back wall, &c. above one another; but as before noticed, the front and end walling is raised only from about one to two or three feet height, for the support of the timber framing for the upright glasses, nearly head high all along the front, both ends corresponding; a door-way for entrance being formed at one or both ends near the back wall; finishing the timber framing of the top or roof over-head in one continued slope, from the top of the back wall to that of the crown timber of the front, erecting cross bars for the support of the slope sashes in two or more tiers sliding one over the other quite home to the crown timbers behind; having no dead roof or cieling in the back part as sometimes practised, but wholly of glass to admit the rays of light, &c. equally in every part; all the glass-work, both front and top sashes being made to slide open occasionally to admit air, &c.

Within side is formed the pit or cavity for the bark bed, and flues for the fire-heat; the pit being ranged nearly the length of the building, six or eight feet wide or more, and three deep; either sunk a little, or raised the greater part above ground, nearly equal to the outer front walls, and formed by a surrounding thin brick wall, and in which is made the bark hot-bed, both for the reception of tender plants plunged therein in pots, and to assist in warming the internal air; next to the bark-pit wall, is a path or walk two feet wide generally continued all round; then along against the inside of the main walling are continued the flues constructed of brick-work on edge; each flue only eight or nine inches wide in the clear, by two or three bricks on edge deep, ranged horizontally one over the other the whole length

of the back wall, in three or four returns communicating with each other; continued also along the end and front walls in one or two ranges, to be used occasionally; furnished with a regulator accordingly, to slide open and shut as required; the whole proceeding from the first lowermost flue, which communicates immediately from the furnace or fire-place, without side, behind, in the bottom, either of the back wall at one end, or in the back part of the end walls as before hinted, and as the situation admits; or if very long stoves of more than forty feet length, two fire places are requisite, one at each end; each having its set of flues ranging half way; each set of flues terminating in an upright chimney at the ends of the back wall without, to discharge the smoke after having spent its heat in its passage through all the returns, for the purpose of heating the whole sufficiently to warm the air within; for in winter and early spring, fires being made in the furnaces every night, the smoke and heat passing immediately into the first bottom flue, thence quickly transmitted through all the others in their several returns, heating them in its passage so effectually, as to warm the internal air in the most agreeable manner, which together with the bark-bed heat, produces a temperature of warmth proper for the growth of all sorts of tender exotics, both woody, herbaceous, and succulent, from the hottest parts of the globe; as some succeed principally in the bark-bed, others best upon the top of the flues and shelves, &c. as is generally noticed in the culture of the respective sorts under their proper genera; hinted also in the article STOVE PLANTS.

The above is a general sketch of the dimensions and formation of a common Stove or Hot-house for general use, proper for the culture of pine apples, and numerous other tender exotics; as well as for forcing flowers, fruits, &c. but for farther particulars of its construction, see the article of its *General Structure*.

But some Stoves are built considerably more lofty and capacious than the above-hinted dimensions, when intended to cultivate the taller exotics in the greatest perfection possible, according to their nature of growth: and for which purpose there are Stoves erected twenty or thirty feet high in the back wall, with width in proportion; by

only five or six feet height in the front glasses, in order to suit low as well as high plants; and with the roof sloped quite from the top of the back wall to the front, and wholly of glass-work, having a capacious bark-pit within, formed mostly towards the front; behind which is sometimes a border of earth to receive tall plants in the full ground; so in this kind of Stove may cultivate exotics, &c. from the lowest to almost the highest stature, placing the shortest growth forward, and the tallest behind, according to their several gradations of height.

However, these very lofty and capacious Stoves are not recommended for general use, they being both very expensive in erecting, requiring also a great force of fire-heat to warm the internal air in winter; and not so well calculated for the growth of the general run of exotics, as Stoves of a moderate height: but persons of fortune and curiosity can indulge their fancy in this respect as they think proper.

But the common Stove first described, of from ten to twelve or fourteen feet high behind, and fourteen in width, by five or six feet height in front, will prove sufficient to raise a great collection of curious tender plants of middling growth.

Thus in these Stove departments, by the constant moderate heat of the bark-bed obtained the year round, and occasional heat of the flues in cold weather, we are able to produce such a temperature of growing warmth in the internal air equally throughout the building, as is eligible for the growth of all sorts of tender exotics from the hottest regions of the East and West Indies, &c. which in this country could not possibly exist, in winter especially, without the constant shelter of such a conservatory, assisted by the above artificial heats of bark hot-beds and actual fire, by which we can imitate the hot climates of Africa, Asia, and America so nearly, as to raise the plants of those countries and make them flourish as in their native soil, and some of them made to yield their fruit in high perfection; exemplified in the *ananas* or pine apple particularly.

Likewise, by the aid of Stoves we are enabled to forward many of our hardy plants to early perfection, such as various sorts of curious flowers, fruits, fallads, kidney beans, strawberries, &c. probably one, two

or three months sooner than they could possibly be obtained in the open ground.

Also many sorts of seeds, cuttings, and layers of exotics are made to grow freely in the bark-bed of the Stove, that without such aids would not grow at all in this country; likewise, even cuttings, &c. of many curious hardy plants that root tolerably in the full ground, may be facilitated very considerably in their rooting by the Stove bark-bed.

Of the different sorts of Stoves.

There are however, different sorts of Stoves used occasionally for different purposes, viz. a Bark Stove for common use, being accommodated both with a bark-bed and flues: a Dry Stove for some particular very succulent plants, &c. is furnished only with flues for fires, and no bark-bed: a Forcing Stove purposely for forcing hardy fruits, flowers, &c. to early perfection; being constructed, some both with bark-bed and flues, and some only with flues and no bark-bed. See each sort described below under their respective heads; BARK STOVE, DRY STOVE, and FORCING STOVE.

BARK STOVE.

The Bark Stove is so called, as being furnished with a pit for a bark-bed, as well as with flues for fire-heat; its general construction has already been described; and is the most universally used, as the most eligible Stove for the general culture of all kinds of the tenderest exotics, as well as for forcing hardy plants, flowers, and fruits occasionally to early perfection; for the bark-bed being designed to effect a constant moderate moist heat the year round; and the flues are used occasionally for fire-heat in winter, or during the cold weather, to produce an additional warmth in the internal air, as may be requisite at that season; the bark-bed being formed of that useful material tanner's bark, commonly called tan, (see BARK BED); and being made the whole width, depth, and length of the bark-pit, is productive of a uniform moderate growing heat of long duration, peculiarly adapted for the immediate reception of many of the tenderest exotics, that require to be constantly plunged in their pots in the bark-bed; such as the pine-apple, &c. in order to enjoy the benefit of that durable, moist, bottom heat about their roots, peculiar to bark hot-beds only, whose heat also evaporates and warms the air of the Stove at all

times; and when the cold in autumn and winter commences, the bark-bed alone not producing a sufficient temperature of heat to warm the internal air effectually, fires are made in the furnace of the flues every night, also on days occasionally during the winter season, to produce an additional internal heat, as before observed; so as the whole may both effectually keep out frosts and the effects of cold damps, and support a constant regular temperature of heat within adapted to the nature of the plants of this department; being generally directed in this by a well graduated botanical thermometer placed constantly in the Stove, distant from the fire-place, and as much in the shade as possible, that neither the fire nor sun may effect it, and only raised by the air of the house; supporting always such a state of heat, as to raise the spirit in the tube to the degree marked *ananas*, the standard for pine-apple Stoves, not exceeding five or ten degrees under or over that standard; which thermometers are certain guides to regulate the proper growing heat requisite for the culture of Stove exotics in this country.

There are hardly any exotics from the hottest parts of the world, either woody, herbaceous, or succulents, but may be cultivated in this kind of Stove (Bark-stove) by placing them in different situations as their natures may require; and many sorts of hardy plants, forwarded in growth, both esculents, flowers, and fruits.

In the arrangement of the plants in this Stove, some require the bark-bed, others succeed in any part of the house; and others, such as the succulents, require the driest situation near the flues: all the more tender, herbaceous, and shrubby plants, natives of the hottest countries generally succeed best plunged in the bark bed; such as the *ananas*, or pine apple; *anacardium*, or cashew-nut; cocoa-nut tree, and many others: though many sorts, both herbaceous and woody, succeed well enough in any part of the Bark Stove; and most of the succulents particularly, may be stationed mostly on the top of the flues or shelves out of the way of moisture, as being of themselves naturally very replete with humidity. And as to many hardy plants designed for forcing, such as strawberries, kidney beans, and various sorts of flowers, &c. that being potted, may be placed upon shelves, or on the parapet wall of the bark-bed; but the nearer the glasses the

the better, particularly the strawberries; but may raise good early kidney beans in almost any part of the Stove; though when intended to forward any sort of flowers, such as roses, pinks, &c. or any bulbous flowers as early as possible, may plunge some in the bark-bed, the others placed upon shelves, &c. will succeed them: thus in this kind of Stove, besides its use for raising pines and other tender plants, may forward numerous hardy plants both for use and curiosity.

DRY STOVE.

This is called a Dry Stove, because it is furnished only with flues for fires and no bark bed; and consequently produces a more dry heat in the air within, than the bark Stoves; intended however, principally for the culture of some very succulent tender exotics of parched soils, that require to be kept always dry; though this was the first invented Stove for general use, before the use of bark-beds was introduced and brought to such perfection in Stoves, where, by their moderate, durable, moist heat we are able to cultivate most sorts of tender exotics generally in greater perfection than in dry Stoves; in which by the constant fire-heat all winter, night and day the fibres of the roots are subject to dry too fast, and prove injurious to many sorts of plants that are not of the very succulent tribe; however, some persons who cultivate full collections of exotics, erect dry Stoves in which to deposite the most succulent plants separate, for fear the other plants which perspire more freely, should occasion a damp air in winter, and be imbibed by the succulents, and injure them, as being impatient of moisture in that season particularly.

In this kind of Stove some moveable stands, or shelves are erected above one another, theatre-ways, on which to place the pots of plants, such as the tenderer sorts of aloes, cereuses, euphorbiums, melon-thistle, and other very tender succulent plants, &c.

FORCING STOVE,

Is intended principally for forcing various sorts of hardy flowers and fruits, &c. to early perfection; some Forcing Stoves being designed entirely for flowers, as is common about London, to force large quantities of early roses, pinks, and numerous other flowers for Covent-Garden market, where they fetch a very great price at an early season. Other forcing Stoves are intended principally for fruit-trees, and some serve

both for forcing flowers and fruits; so that these forcing Stoves consist of two kinds, viz a bark Forcing Stove being furnished both with a bark-bed and flues; a fire Forcing Stove having only flues for fires and no bark-bed.

The former of which, the bark Forcing Stove, is constructed like a common bark Stove already described, being furnished with a pit for a bark-bed to receive the pots of flower-plants intended for forcing, and with flues for fire-heat occasionally; and sometimes is formed capacious enough in width to admit of a border of earth behind the bark-bed next the back wall; sometimes also, a small one in front, both of which serving for fruit-trees, to be planted in the full ground; such as cherries, peaches, apricots, &c. for early forcing; and the bark-bed is for receiving various sorts of flower plants in pots in winter, for forcing into bloom early in spring; such as the finest roses, honeysuckles, pinks, narcissus, early tulips, and other flower plants, both shrubby, herbaceous, and bulbous, that may be required early in flower; also may forward any curious tender annual flowers in the bark-bed, such as balsamines, &c. likewise may have pots of strawberries, dwarf cherries, and other small fruits plunged either in the bark bed, or placed any where towards the glasses; also pots or boxes of kidney-beans, sallading, &c.

Observing, the season to begin forcing or fire-working this Stove, is principally from about Christmas to Candlemas, according to the earliness the flowers and fruits may be required; having the plants intended for forcing, previously potted either in the preceding spring or autumn, and in winter sheltered from severe frost till the forcing time arrives; but the shrub and tree kinds in particular, if potted the former year, to be well rooted and established in the pots will be an advantage; remarking, the fruit-trees should all be previously trained in the open ground to a bearing state; then those intended for the borders of earth behind the bark-pit, &c. may be planted fully therein early in autumn, without being potted; some of which, such as peaches, nectarines, apricots, &c. to be there trained as wall-trees, others as low standards, particularly cherries. And vines planted also against the front without-side, may be trained in; as directed below in the fire Forcing Stove.

That

That therefore, the forcing season being arrived; having previously prepared the bark-bed accordingly, and plunged the plants you intend therein, also many small kinds, such as pinks, strawberries, and any other low flower plants, &c. in pots placed upon shelves near the front and top glasses; and the fruit-trees being some in pots, placed any where the most convenient, others planted fully in the borders, if any; they will all soon be set in motion by the bark-bed heat; afterwards begin also making moderate fires on cold nights, likewise on days occasionally, in very severe weather, to support a constant proper warmth to continue the plants always in growth moderately; and thus may obtain various flowers and fruits two or three months before their natural season in the open air.

The other kind of Forcing Stove, worked by fire-heat only, is furnished with flues and no bark-bed, but otherwise constructed like any other common Stove, having flues all round the inside walls for fire-heat; and is designed principally for forcing fruit-trees, having the whole bottom space within formed of good rich earth full two feet deep, in order to plant the fruit-trees entirely in the ground to remain; an alley or walk being either formed next the back wall, or carried along the middle, or continued quite round the back and front, allotting a small border however close along the back and front, for the reception of the choicer fruits to be trained as wall-trees; and the main middle space for standards of moderate growth.

Here may be planted for forcing, the best sorts of apricots, peaches, nectarines, cherries, plums, vines, and figs; likewise, any small fruit-plants, as gooseberries, currants, raspberries; also tufts of strawberries. All of which being first trained in the open ground to a bearing state.

For in this kind of Stove, having the whole bottom space formed of good rich earth as before observed, it admits of planting the trees, in the full ground; peaches, nectarines, apricots, grapes, and figs principally against the back wall and front, and trained to a trellis as wall-trees; others, such as cherries, are planted as standards, both moderate full standards, half standards, and dwarfs, ranged in lines from the back to the front, the tallest behind, and the lowest forward; and between them may have smaller plants, planted also in the ground; also pots of

strawberries and low flowers, upon shelves near the glasses: and vines being also planted without side, close against the front wall, are drawn in through a small hole made for each, either in the wall, or in the timber of the front erections; and the branches within are trained up to the inside of the slope glass upon trellis work, where they often produce abundance of fine fruit at an early time.

This kind of Stove is worked entirely by fire-heat, and the season to begin forcing or make the fires, is January or early in February, continuing it moderately every night during the cold weather in winter and spring, to forward the different fruits to as early perfection as possible.

Some other sort of forcing Stoves for fruit-trees, are contrived also with a low pit for a bark or dung hot-bed, or dung and bark together; beginning first to force the trees moderately with only the hot-bed heat; afterwards, gradually apply the fire-heat on nights, encreasing its strength by degrees.

In all these kind of forcing frames, every summer after their trees have yielded their produce, the top glasses should be removed to admit the free air, showers, &c. to strengthen and harden the shoots of the year properly, and should remain open until winter; but for more particulars in respect to forcing fruit-trees, see the article FORCING FRAME.

The different structures of Stoves.

Stoves for the various purposes above noted, are formed upon different plans, according to the fancy of the owner or inventor; though there is only one good plan we would recommend for general use.

We formerly noticed that Stoves are for the general part ranged lengthways nearly east and west, that the glasses of the front and roof may be full upon the sun; this will be found to be the most convenient and eligible plan for a common Stove for general use, for the purposes before mentioned, either for a common bark Stove for pines and other exotics; a dry Stove, or any kind of forcing Stove.

There are however, Stoves of late inventions erected on the following plans.

Some, instead of ranging lengthways east and west, are ranged directly south and north, having a double sloped glass roof, being sloped to each side like the roof of an house, sloped also at the front or south end; both

both sides and the front end being of glass; which kind of Stove, as to dimensions, is from twelve to sixteen or twenty feet wide, the length at pleasure; and from ten to twelve or fourteen feet high in the middle, both sides nearly head height; is formed by a brick wall all round, raised only two or three feet on both sides, and south end; but raised at the north end like the gable end of a house, to correspond with the above-mentioned double sloped glass roof; and upon the top of the side and south walling, is erected the framing for the glass-work, which is sometimes formed with a two feet upright, immediately on the top of the wall, and sloped to each side above; and sometimes is wholly of a continued slope on both sides, immediately from the wall to the top or ridge: within, it is furnished either with one or two bark pits; but if of any considerable width, generally with two pits ranging parallel, one under each slope of the top glass; separated by a two-feet path running along the middle of the Stove; may also be continued all round each pit; and with flues ranged along against the inside walls, or round that of the pit; sometimes also, under the pavement of the walk or alley; the whole terminating in an upright funnel or chimney at the north end.

Other kinds of Stoves are formed entirely square, having a ten or twelve foot brick wall behind; that of the front and both sides, only two or three feet high for the support of the glass-work, placed upright nearly the same height, and sloped above on both sides and front, also wholly of glass; and is furnished within with bark-pit and flues like the others.

And some Stoves are made semicircular, others entirely circular, formed with a two or three-feet brick wall supporting the glass framing, which is continued quite round; having the bark-pit also circular, and flues carried all round the inside of the walling, terminating in a chimney on the northern side.

However, we have in general observed, that the common straight Stoves ranging in a line nearly east and west, with the main range of glass work in front and top full upon the south, as before hinted, are the most commodious, as well as generally prove the most successful in the end, take summer and winter, both for the culture of all kinds of Stove exotics; also for forcing any kinds

of fruits, flowers, and esculents; and is the plan we would recommend for general use: there are however, hot-houses or Stoves of this plan of different dimensions and constructions, according to the sizes of the plants they are designed to contain: though the most general Stoves for all the aforementioned purposes are but of moderate height, not exceeding ten or twelve, or fourteen feet at most behind, and five or six in front, as in all common pine-apple Stoves; but some are built very lofty behind, perhaps twenty or thirty feet height as before observed, to admit of the taller exotics being placed towards the back part, and grow up to their full stature; but Stoves of a moderate height as above, are best adapted to the culture of pines and other moderate-growing plants, as well as for forcing. Very lofty Stoves require both a greater force of heat to warm the enclosed air effectually, and the glasses being so high, the plants receive less benefit of the sun, and are apt to draw the pines, &c. up too fast into long slender leaves, as they naturally aspire towards the glasses as fast as possible; but in lower Stoves, where the top glasses are but a moderate distance from the plants, they receive the benefit of the sun's heat better, and do not draw so fast in stature, but become more stocky at bottom, and assume a more robust firm growth, particularly the *ananas* or pine apple, and thereby more capable of producing large fruit: on which consideration, such Stoves or hot-houses that are intended principally for the culture of the *ananas*, and other moderate exotics, and for forcing flowers, fruits, &c. should never be built very lofty, but of the moderate height before observed, which will be found very eligible dimensions.

It may be observed from the hints already exhibited, that a Stove may be large or small, according to fancy or convenience; for in a small or moderate sized Stove, a person may indulge his fancy with a great number of the more curious sorts of tender exotics, as well as forward many sorts of hardy flowers and fruits to early perfection, at a moderate expence for bark and fuel; but where a more general or grander collection is required, either for pleasure or profit, the dimensions of the Stove must be enlarged proportionably; so that a common Stove for either, or all of the aforementioned purposes, may be of any length, from fifteen or twenty, to fifty or an hundred feet, as already hinted,
by

by twelve to fourteen or sixteen feet wide; ten to fourteen feet high behind, by five or six in front, wall, and upright glass-work together, as before observed. — See the particulars below.

Its General Structure, &c.

Having however determined on the size or dimensions, as to length and width, &c. of the intended Stove, the following are some more full and general sketches of the dimensions and construction of the different parts of the building, supposing it is designed as a common bark Stove for general use; being furnished with a bark-pit and flues, &c. which may also serve as hints for the erection of any other sort of Stove.

Proceeding therefore to set out the foundations of the walls accordingly of brick-work, allowing also due width at bottom to support the flues a foot wide, wholly on the brick foundation; then setting off the back or north wall a brick and half or two bricks thick; and the front and end walls nine inches, carrying up the back wall from ten to fourteen feet high; but that of the front and ends only from one or two feet to a yard high, upon which to erect the upright timber framing for the perpendicular glasses; previously observing in carrying up the walls, to allot a proper space for a door-way at one or both ends towards the back part; setting out also the furnace or fire-place of the flues near the bottom, generally towards one end of the back-wall behind, formed also of brick-work, and made to communicate with the lowermost flue within; though if a very long Stove, of more than forty feet length, a fire-place at each end will be necessary; or if more convenient, may have them in the back part of the end walls; in either case, forming them wholly on the outside of the walls, about fourteen or sixteen inches wide in the clear, but more in lengthways inward; the inner end terminating in a funnel to communicate internally with the flues as above observed; fixing an iron-barred grate at bottom to support the fuel; calculated either for coal, wood, peat, turf, &c. as may be the most conveniently obtained; an ash-hole being underneath, and just above it, is the mouth or fuel door to admit the fuel, &c. being about ten or twelve inches square, having an iron frame and door fixed to shut with an iron latch as close as possible; raising the whole furnace

sixteen or eighteen inches in the clear, finishing the top archways; carrying up the main walls as you go on.

Thus far observed, continue carrying up the walls of the building the thickness and height above mentioned; and within-side, erect the flues close along the walls a foot-wide, formed with brick-work on edge, the first lower flue communicating with the furnace or fire-place without, and raised a little above it to promote the draught of heat more freely; continuing it along nearly even with the intended level of the floor of the Stove, close to the wall, only eight or nine inches wide in the clear, as before observed, and three bricks on edge deep, returning it three or four times over one another in the back wall, and in the others, one or two as they admit, each return two bricks on edge deep; and may contrive a sliding iron regulator to draw outward in the beginning of the first flues to admit more or less heat as may be required; being careful that the brick-work of each flue, as they proceed, is closely jointed with the best mortar, and well plaistered within that no smoke can break out, having each return closely covered with broad paving tiles; and the uppermost or last flue to terminate in an upright chimney at one end of the back wall; or if two sets of flues, a chimney at each end as formerly observed, contriving an iron slider outward at the end of the last flue next the chimney, to confine the heat more or less occasionally as required, either by the heat going off too fast, or is become too low and weak.

Some in erecting the flues, to make the most of the fire-heat with as little fuel as possible, form one or two spare flues to use occasionally, by means of sliding iron regulators to admit the heat as may be required for the smoke to spend itself wholly in the flues before it discharges itself at the chimney; which spare flues are sometimes carried along under the pavement of the floor of the walks; and sometimes carried up against the outside of the parapet wall of the bark-pit, but detached an inch or two to form a vacancy for the heat to come up without drying the bark too much.

Sometimes also, all the flues of some Stoves are built entirely detached, perhaps two or three inches from the walls, in order that the fire-heat may diffuse itself from both sides of the flue.

Should

Should be very careful, that neither the fire-place or flues is carried too near any of the wood-work, lest it should take fire.

Proceeding however within, to set out the cavity for the bark-pit, first allowing a space next the flues for a two-foot path or walk all round, and then of the whole middle space is formed the pit for the bark-bed, six or eight feet wide, the length in proportion to that of the Stove, and a yard deep; being formed by a surrounding wall, and may either be sunk at bottom a foot or more in the ground, raising the rest above, by means of the raised parapet wall; or if there is danger of wet below, it should be raised mostly above the general surface; and in either case, surrounding it wholly in width, length, and depth with a nine-inch wall; though a brick-wide wall is often made to do, especially that which forms the parapet above ground; coping it all round with a timber, plate, or kirb, framed and mortised together, which effectually secures the brick-work.

Then the bottom of the pit should be levelled and well rammed, and if paved with any coarse materials, it would be an advantage in preserving the bark.

The path or alley round the pit should also be neatly paved with brick or stone; this walk being very necessary for the convenience of performing the occasional operations of culture, as well as to admit of walking round to view the plants and gather the produce of such as yield any; though sometimes to save room, the path is only continued along the back and end of the pit, having the pit continued in width quite up to the front wall, which is previously raised a little in proportion; though it is considerably the most convenient to have a walk quite round the bark-bed.

Next, in respect to the timber framing, and glass-work for enclosing the whole, consisting wholly of a close-continued range of glass sashes all along the front, both ends, and roof, quite to the top of the back wall; each sash being a yard, or three feet six inches wide; and for the support of which, framings of timber are erected on the brick-walling conformable to the width and length of the sashes.

So that for the reception of the perpendicular glasses in the front and ends, a substantial timber plate is placed along the top of the front and end walls, upon which is erected upright bars at eligible distances, framed to a plate or crown-piece above, of

sufficient height to raise the whole front head high, both ends corresponding with the front and back; a plate of timber being also framed into the top of the back wall, to receive the sloping bars from the framework in front; proper grooves or channels being formed in the front plates below and above, to receive the perpendicular sashes, sliding close against the outside of the uprights all the way along the front, or may be contrived for only every other sash to slide one beside the other, as may be convenient, for admitting fresh air, &c.

From the top of the upright framing in front, are carried substantial cross bars or bearers sloping to the top of the back wall, where being also a timber-plate, are framed at both ends to the wood-work at due distances, to receive and support the slope glasses of the roof, ranging generally in two or more tiers, sliding one over the other, of sufficient length to reach quite from the top of the upright framing in front, to the top of the back wall: the cross bars being grooved for the sashes to slide up and down occasionally over one another, making the upper end of the top tier of glasses, shut close up to the plate in the wall behind, running under a proper coping of wood or lead, fixed along above close to the wall, and lapped down of due width to cover, and shoot off the wet sufficiently from the upper termination of the said top sashes; though some very wide Stoves, exclusive of the main slope sliding glasses, have a shorter upper tier of glass always fixed in the same place; the upper ends close to the back wall secured under a coping as above, and the lower ends lapping over the top ends of the upper sliding tier, and this over that below in the same manner, to shoot the wet clear over each upper end or termination; likewise along the under outer edge of the top plate, or crown-piece in front, may be a small channel to receive the water from the slope glasses, and convey it to one or both ends without running down upon the upright sashes; being careful that the top of all behind is well framed and secured water-tight, and finish the top of the back wall with a neat coping the whole length.

In every part, the bars of wood which support the glasses should be neatly formed, neither made very broad nor thick to intercept the rays of the sun; making those however at top strong enough to support the glasses without bending under them.

The

The glazing of the sashes should generally be in the imbricated manner, more especially the slope sashes of the roof; so that the panes of glass should be laid in putty, with the ends lapping over each other about half an inch; the vacancies of which are by some closed up at bottom with putty, others leave each lapping of the panes open, in order both for the air to enter moderately between the squares of glass, and likewise that the rancid vapours arising from the fermentation of the bark-bed, &c. within, may be kept in constant motion without condensing much; and that such as condense against the glasses, may discharge itself at those places without dropping upon the plants; but as to the upright sashes in front, they may be either glazed as above, or the panes laid in lead work; being very careful in both places to have the glazing well performed proof against wet.

A door way for general entrance having been formed at one end of the building near the back wall, the door of which may either be wholly of wood, or the upper half may be sashed and glazed to correspond with the other adjoining glass-work of the ends.

Within-side of the building, the walls should be plaistered, pargetered, and white-washed; and all the wood-work, both within and without, painted white in oil colour for its preservation, and to give the whole a lively appearance, as well as to reflect the rays of light upon the plants on nights, which is supposed proves of some importance in improving their growth.

As to any necessary internal erections, there may be one or two ranges of shelves for pots of small plants, erected near the top glasses towards the back part, supported either by brackets suspended from the cross bars, or by uprights erected on the parapet wall of the bark-pit: a range or two of narrow shelves may also be placed occasionally along the front-glasses, and both ends; all of which shelves will serve for holding pots of many sorts of small plants, that do not require to be plunged in the bark-bed; also for pots or boxes of strawberries, cucumbers, flowers, &c. in winter, and early in spring for forcing; which being placed as near the glasses as possible, are generally the most prosperous and successful in their respective crops.

In very wide Stoves, if the cross bars or bearers of the slope or top glasses appear to

want support, some neat uprights either of wood or iron, may be erected upon the bark-bed walling, at convenient distances, and high enough to reach the bearers above, and support them effectually in their proper position without bending under the glasses.

Without side of the Stove over each fireplace, should generally be erected a small covered shed with a door to shut, for the convenience of attending the fires, and keeping them regularly burning.

Or if the situation admitted, a close shed might be erected all the way against the north side of the back wall, which will defend the back of the Stove from the outward air; and if the fire places are behind, it will be convenient for attending and preserving the fires as aforesaid; serving also to stow fuel for the general use of the Stove, also for garden tools, and all garden utensils when not in use, to preserve them from the weather.

It is likewise of importance to have covers for the glasses, to draw over occasionally in severe frosts and hail storms, more particularly the top sashes; for which purpose some use wooden, or canvas sliding shutters fitted to the width, &c. of the frames of the sashes so as to slide on and off presently; others use rollers of painted canvas or tarpaulin rolled up on long poles or rollers, and fixed lengthways all along the top of the Stove just above the upper ends of the top sashes; which, by means of lines and pullies, are let down all at once in a minute, and by the same means are rolled up again almost as expeditiously: some Stoves however, have neither shutters nor rollers for covering; using only either large bafs mats or reed mats occasionally for the slope glasses, especially in severe frosts; though it is also proper to defend the upright glasses on nights particularly, in very rigorous weather.

Thus far is principally all we have to say concerning the general structure of a bark Stove, which may serve to convey some necessary hints, both for the erecting of this, and any other sort of Stove; and as most builders are now well acquainted with the general plan, by giving the intended dimensions as to size, &c. to the different workmen concerned, such as bricklayers, carpenters, and glaziers, they can readily execute it, and finish the whole completely, as in other buildings.

The above kind of Stove is calculated not only as a pinery for the culture of the
6 H pine-

pine-apple, but for all sorts of tender exotics of similar quality; some requiring to be plunged in the bark-bed, others placed on the top of the flues and shelves, and others nearer the glasses: the same Stove serves also to force fruits, and flowers, &c. as already hinted.—See STOVE PLANTS.

Remark however, that such Stoves as are intended principally for pine-apples, and for forcing flowers, strawberries, dwarf fruit-trees, and small culinary esculents, &c. may be only ten feet high behind, and which generally succeed better for these plants than stoves of more lofty dimensions, for the reasons already observed.

Likewise, by raising the bark-pit within wholly above the surface, elevates the plants plunged therein nearer the glasses, and proves advantageous in their growth.

In erecting Stoves, to save some expence, any garden-wall already built in an eligible exposure may be made to serve as the back wall to the building.

Nursery and Succession Stove.

Besides the main bark Stove above described, it is very convenient to have one or two smaller, as a nursery-pit, and a succession Stove, particularly where large collections are required, and more especially in the culture of large quantities of pine apples; one serving as a nursery-pit, in which to strike and nurse the young off-spring crowns, and suckers of the old pines for propagation; the other as a succession-house for receiving the year old plants from the nursery-pit, and forwarding them a year to a proper size for fruiting, as succession plants, to furnish the main Stove or fruiting-house every autumn, to succeed the old plants then done fruiting.

These smaller Stove departments prove materially useful in the culture of pines, particularly to raise and nurse the young plants, until arrived to a proper age and size to produce fruit; then moved into the main Stove or fruiting-house, which being thus supplied from these smaller Stoves, with a succession of fruiting plants annually, without being crowded or incommoded with the rearing of the said succession plants, proves a particular advantage, not only in the culture of the fruiting plants, as they often require a higher degree of heat than the succession plants at particular times, in order

to forward and improve the growth of fruit properly; but it is also making the best advantage of this main department, to have the bark-bed always filled with fruiting plants only, producing a full crop of proper sized pine-apples every year, which could not always be effected with such certainty and perfection without the aid of these succession Stoves; because the pine-plants in their infant state require sometimes different management from the fruiting plants, particularly in respect to the degree of fire-heat as abovesaid, which in general should be more moderate than for the fruiting plants, lest too much heat force them into fruit in their minor growth, when incapable of producing it in any tolerable perfection.

Therefore, these smaller succession Stoves may be erected as appendages to the main house, or may be detached at some distance as may be convenient; though if the situation admits, it may be both more convenient and ornamental to join them in a line with the main Stove, one at each end, and nearly of the same construction; but may be smaller, both in length, width, and height, if thought proper; and sometimes for cheapness, are formed without any upright glasses in front, having a wall all round, five or six feet; behind gradually sloping at each end, to three or four in front; and with only sliding glasses at top, more particularly the nursery Stove, commonly called simply the pit, because the whole internal space in length and width, is often allotted intirely as a pit for a bark-bed, frequently without any walk within, or door for entrance; the necessary culture being performed by sliding open the glasses at top, and the flues for the fires being formed in the upper part of the back wall: however, it may be more eligible to form the succession Stove particularly, nearly like the main one, with erect glasses in front, and sloping sashes at top, with a door for entrance, and an alley or walk next the back wall at least.

Observing however, if these smaller Stoves are joined to the end of the main one, they may be divided from it only by a sliding glass partition for communication with each other, particularly the succession and main Stove; but with separate furnaces, and flues to each department; because the young pine-plants do not at all times require the same degree of fire-heat as the older pines, especially those of proper size for fruiting; so that

that by having separate fires, the heat can be regulated accordingly.

The nursery Stove or pit, may be of smaller dimensions in respect to width and height, than the succession house, if thought convenient: and if designed wholly as a pit without any path or walk within, six or eight feet width may be sufficient, by five or six high in the back wall, and four in front, the whole internal space being filled with tan three feet deep to form the bark-bed: serving chiefly as a nursery in which to strike and nurse the annual increase of crowns and suckers, of the *ananas* or pine-plants the first year; also to raise many tender plants from seeds, cuttings, &c. without incumbering the main Stove; and when they are forwarded to such a state of growth as to require more room, they are removed to the succession-house.

But the succession-house may be nearly on the plan of the main Stove, though of smaller dimensions both in width and height; and is intended to receive the year-old pine-plants from the pit or nursery Stove, in order to plunge them at greater distances, sufficient to give the whole proper scope to take their full growth another year, when they will generally be arrived to a proper size for fruiting the year following; being previously removed in autumn to the main fruiting Stove to succeed the old fruiting plants, which generally by October have all yielded their produce, are then removed away, and their place supplied by a sufficient quantity of large plants from the succession house, being arrived to a proper state of growth to produce fruit next summer: and the succession-house is at the same time replenished with the largest plants from the nursery-pit, which next autumn will probably be also arrived to a proper size for removing to the fruiting-house to succeed the others.

Thus by having the different Stove departments always furnished with pine plants of three different stages of growth, succeeding one another regularly, i. e. the nursery pit containing the yearly crowns and suckers, the succession pit the one and two-year plants, and the main Stove the fruiting plants, a constant succession of fruiting plants is thereby annually obtained; for the same individual plants never produce fruit but once; they however, produce a plentiful supply of crowns and suckers which commence proper plants, attaining a fruiting state in regular succession.

However, in many places the situation or convenience not admitting but of one common Stove to raise and forward the pines and other exotics, in their different stages of growth, or at least with probably the assistance only of a small detached bark-pit, or a bark and dung hot-bed under a large garden frame, to strike and nurse the yearling crowns and suckers of the pines, &c. of each year, until they are about a year old, then moved into the Stove: yet with proper care and ingenuity often produce very good pine apples, as well as raise many other curious exotics, and forward flowers to early bloom; also early fruit and some culinary esculents.

But having a main Stove with two smaller ones adjoining, nearly on the same plan as above hinted, we can always with greater certainty, obtain a regular annual succession of fruiting pines in perfection.

Remarking, that in all these Stoves there may, besides pine apples which generally occupy the bark-bed, either wholly or in part, be retained numerous other tender curious exotics from the hot parts of the world, that require aid of a hot-house in this country; some placed in the bark-bed as their nature may require, others upon the top of the flues, top of the bark-pit wall, and upon shelves; all of which is generally hinted in the culture of the respective sorts, a list of which is exhibited below, being collected into one point of view under the head *Stove Plants*; shewing at once all the principal Stove or hot-house plants, from the hot parts of Africa, Asia, and America, now inhabitants of the English gardens; with hints for their general culture, referring to their proper genera for particulars; likewise, a list of such hardy flowers, fruits, and culinary esculents, as may be forwarded to early perfection by the assistance of these departments.

Supposing however, the Stove or Stoves are now erected, and ready for the reception of the various plants intended; then observing of the bark Stove, that preparations must be made early in autumn, to fill the bark-pit thereof with tanner's bark to form the bark hot-bed, for the immediate reception of the tenderer kinds of plants, to be plunged therein, each in its proper pot; this kind of hot-bed being the most eligible for all kinds of Stoves or hot-houses, as by its moderate and durable fermentation, no

material

material yet known equals it for a hot-bed ; it effecting a uniform lasting heat, of a temperature peculiarly adapted to the growth of pine-apples, and many other tender exotics of similar quality. — See BARK BED.

The autumn, about September or early part of October, is the general season for filling or replenishing the bark-pit with fresh bark or tan, that the bed may support a constant lively heat during the winter : however, the work may also be performed occasionally in spring, or any time of the year, as occasion may require.

But for the general management of the Stove or hot-house, and the plants thereof, see STOVE PLANTS below ; in the article of their *General Culture*.

STOVE PLANTS.

Having exhibited in the foregoing head general hints of the form, dimensions, and construction of the different sorts of Stoves, and their respective uses in the culture of plants, we now proceed to a list of all the principal Stove plants, or such tender exotics from the hot parts of the world, that require the aid of a Stove to preserve them in this country ; and although they are separately and fully treated of under their respective genera, yet by collecting them under one point of view in this place, each under its generical name, with short hints of their nature, by distinguishing which are shrubby, herbaceous, and succulent, will, we presume, assist the memory in making a collection ; referring to their respective genera, for the particulars of their respective description and culture.

ACANTHUS, Bear's-breech. — Shrubby, holly-leaved *Acanthus*. (*Undershrubby*.)

ACHRAS, Sapota or Mammee-tree. — Common Sapota. — Mammee Sapota. (*Trees*.)

ACHYRANTHES, Bloody or Red Indian *Achyranthes*. — Woolly-cupped Indian *Achyranthes*. — Lapaceous or Bur-flowered Indian *Achyranthes*. — Prickly-cupped shrubby Indian *Achyranthes*. — (*Mostly herbaceous, and the last shrubby*.)

ADANSONIA, Æthiopian Sour Gourd. (*Tree*.)

ADENANTHERA, Bastard Flower Fence. — *Pavonina*. — *Falcataria*. (*Trees*.)

ÆSCHYNOMENE, Bastard Sensitive plant. — Tree *Æschynomene*. — Grandiflorous *Æschy-*

nomene. — Sesban, or Ægyptian *Æschynomene*. (*Woody*.)

AGAVE, American Aloe. — Viviparous American Aloe. — Stinking American Aloe. (*Succulents*.)

ALETIS, Guinea Aloe. — Hyacinth-flowered *Aletis*. — Ceylon *Aletis*. — Cape *Aletis*. — Fragrant *Aletis*. (*Succulents*.)

ALOE, African Aloe. Most of the species, except the *Aloe Uvaria*, may be considered both as green-house and Stove plants ; for, although they may all be wintered tolerably well in a green-house, yet if placed in the Stove, in winter particularly, they more certainly flower annually in greater perfection. (*Succulent*.)

AMARYLLIS, Lily Daffodil. — Jacobæan Lily. — Mexican Lily. — Zelon Lily. (*Herbaceous and Bulbous*.)

AMOMUM, Ginger. — Common Ginger. Broad-leaved wild Ginger, &c. (*Herbaceous*.)

ANACARDIUM, Acajou or Cashew-nut. (*Tree*.)

ANNONA, Custard-apple. — Netted Custard apple. — Prickly Custard apple. — Scaley Custard apple, or Sweet Sop. — Marsh *Annona*, or Water apple. — Broad-leaved *Annona*. (*Tree and Shrub kinds*.)

APOCYNUM, Dog's-bane. — Shrubby upright Ceylon *Apocynum*, with varieties. — Climbing Dog's-bane, with varieties. — (*Shrubby*.)

ARUM, Wake-Robin, &c. — Ægyptian *Arum* or Colocasia. — Trilobate Indian *Arum*. — Tree *Arum*. — (*Two first herbaceous, the other somewhat ligneous*.)

ARUNDO, Reed. — Bamboo Cane, or Indian tree-Reed. (*Ligneous*.)

ASCLEPIAS, Swallow-wort. — American Scarlet *Asclepias*, &c. — (*Herbaceous but ligneous stalked*.)

ASPARAGUS, Sparagras. — Tree *asparagus*, or Dragon-tree. (*Woody*.)

BARLERIA, several Species. (*Herbaceous and Shrubby*.)

BASELLA, Malabar Nightshade. — Red Malabar Nightshade. — White Malabar Nightshade. (*Herbaceous*.)

BAUHINIA, Mountain Ebony. — Prickly *Bauhinia*. — Tomentose *Bauhinia*. (*Shrubby*.)

BIGNONIA, Trumpet-flower. — Several species. (*Chiefly Woody*.)

BIXA, Dying Metella, &c. (*Shrubby*.)

BOCCONIA, Tree-celandine. (*Shrubby*.)

BOMBAX, Silk Cotton-tree. — Thorny *Bombax*, or Ceiba. — Pentandrous, smooth *Bom-*

Bombax. — Heptaphyllous smooth *Bombax*. (Trees.)

BONTIA, Barbadoes Wild Olive. (Shrubby.)

BROMELIA, *Ananas*, Pine-apple. — Common *Ananas* or Pine-apple. — Wild Pine-apple or Pinguin. — *Karatas*, or Acaulous wild Pine-apple. — Pyramidal *Bromelia*. — Lingulated *Bromelia*. (Herbaceous.)

BRUNSFELSIA, *Brunsfelsia*. (Shrubby.)

BUDDLEJA, American *Buddleja*. — Occidental *Buddleja*. (Shrubby.)

CACTUS, Melon-thistle, Torch-thistle, &c. — Greater Hedge-hog Melon-thistle, with Varieties. — Mammillary, or Smaller Melon-thistle. — Torch thistle, several upright sorts. — Creeping or trailing Torch-thistle. — Climbling Torch-thistle. — *Ficus Indica*, or Indian Fig. — Greater Indian Fig. — Cochineal Indian Fig. — Indian Fig of Curassoa. — Sword-leaved *Opuntia*. — *Periskia*, or American Gooseberry. (All of the Succulent tribe.)

CAPSICUM, Guinea-Pepper. — Shrubby *Capsicum*, with many varieties. (Shrubby.)

CARICA, Papaw or Pepo-tree. — Common Indian Papaw-tree. — Posoposa, or Branching Surinam Papaw-tree. (Tree like.)

CASSIA, Wild Sena. — Purgine-tree *Cassia*. — Biflorous shrub *Cassia*. (Tree and Shrub kinds.)

CATESBEA, Lily-thorn. (Shrubby.)

CEANOETHUS, New Jersey Tea. — Asiatic *Ceanothus*. (Shrubby.)

CESTRUM, Bastard Jasmine, or Jasminoides. — Nocturnal *Cestrum*. — Diurnal *Cestrum*. (Shrubby.)

CHAMÆROPS, Dwarf Palm or Palmetto. (Frondose.)

CITHAREXYLON, Fiddle Wood. (Shrubby.)

CLUTIA, *Elutaria*, or Indian *Clutia*. (Shrubby.)

COCOS, Cocoa-nut-tree. (Frondose Tree-kind.)

COFFEA, Coffee-tree. (Shrub-like.)

COTYLEDON, Navel-wort. — Cut or jagged-leaved *Cotyledon*. (Succulent.)

CRESCENTIA, Calabash-tree. (Tree kind.)

CRINUM, Asphodel-lily. — American Asphodel-lily. — Asiatic Asphodel-lily. (Bulbous herbaceous plants.)

ELÆAGNUS, Wild Olive, or Oleaster. — Thorny *Elæagnus*. (Woody.)

ERYTHRINA, Coral-tree. — *Corallodendron*, or Smooth Coral-tree. — Spinous Coral-tree.

—Herbaceous *Erythrina*. (Shrubby and Herbaceous.)

EUPHORBIA, Burning Thorny Plant. — *Euphorbia* of the Ancients. — Canary *Euphorbia*. — Oleander-leaved *Euphorbia*. — Medusa's-Head *Euphorbia*. — Tithymaloide *Euphorbia*, or Bastard Spurge. (All Succulent.)

FICUS, Fig tree. — Sacred Fig, or Indian God-tree. — Sycamore Fig-tree. — Bengal Fig-tree. — Indian long-leaved Fig tree. — Dwarf Indian Fig-tree. (Tree kinds.)

GARDENIA, Cape Jasmine. (Shrubby.)

GLORIOSA, Superb Lily. (Herbaceous.)

GOSSYPIUM, Cotton-plant. — Consists of herbaceous and shrubby species. See *Gossypium*.

GREWIA, Oriental *Grewia*. (Shrubby.)

HÆMANTHUS, Blood-flower. — Scarlet *Hæmanthus*. — Reddish *Hæmanthus*. — Carinated *Hæmanthus*. — Ciliated *Hæmanthus*. (Herbaceous bulbs.)

HÆMATOXYLUM, Blood-wood, or Logwood. (Tree-like.)

HERNANDIA, Jack-in-a-box-tree. — Sonorous *Hernandia*. — Oriental *Hernandia*. (Trees.)

HIBISCUS, Syrian Mallow. — Mutable-flowered *Hibiscus*, or China Rose. — *Rosa Sinensis*, or Rose of China. — Viscous Mallow, or Scarlet *Hibiscus*. (Shrubby.)

HURA, Sand Box-tree. (Woody.)

IATROPHA, Cassada, or Cassava Plant. — Most of the species are Stove-plants. (Woody and herbaceous.)

JUSTICIA, Malabar-nut. — Hyssop-leaved *Justicia*, &c. (Woody.)

KÆMPFERIA, *Galangale*. — Both the species (Herbaceous.)

LANTANA, American *Viburnum*. — Trifoliate *Lantana*. — Involucrum-headed *Lantana*. — Camara, or leafless-headed *Lantana*. — Prickly *Lantana*. (Shrubby.)

LOBELIA, Cardinal flower. — Plumier's *Lobelia*. — Surinam *Lobelia*. — Pine-leaved *Lobelia*. (Shrubby.)

MALPIGHIA, Barbadoes Cherry. — All the species. (Woody.)

MAMMEA, Mammee-tree. — American Mammee tree. — Asiatic Mammee Tree. (Trees.)

MARANTA, Indian Arrow-root. — Arundinaceous *Maranta*. — Galanga, or Indian Arrow-root. (Herbaceous.)

MARTYNIA. — Perennial *Martynia*. (Herbaceous.)

MELIA, Bead-tree.—Evergreen Bead-tree of Ceylon.—*Azadirachta*, or Indian Bead-tree. (*Tree kinds.*)

MESEMBRYANTHEMUM, (*Ficoides*) Fig Marigold.—Diamond *Ficoides*, or Ice-plant. (*Herbaceous and Succulent.*)

MIMOSA, Sensitive plant.—All the species. (*Shrubby and Herbaceous.*)

MUSA, Plantain-tree.—All the three species. (*Of a Tree-like growth, but Herbaceous nature.*)

MYRTUS, Myrtle-tree.—Pimento or Allspice-tree.—Dioecious Myrtle.—Brazilian Myrtle, &c.—(*Tree and Shrub kinds.*)

NERIUM, Oleander.—Double-flowered.—Striped-leaved, &c. (*Shrubby.*)

NYCTANTHES, Arabian Jasmine.—Sambac, or Common Arabian Jasmine.—Undulate-leaved *Nyctantes*, or Malabar Jasmine.—*Arbor Tristis*, or Sorrowful-tree.—Hairy Sorrowful-tree. (*Shrubby.*)

PANCRATIUM, (*Pancratium lily*) Sea Daffodil.—Ceylon uniflorous *Pancratium*.—Mexican biflorous *Pancratium*.—Caribbean multiflorous *Pancratium*.—Carolina multiflorous *Pancratium*.—Amboyna broad-leaved *Pancratium*. (*Bulbous Herbaceous perennials.*)

PASSIFLORA, Passion-flower.—Sawed-leaved Passion-flower.—Laurus-leaved Passion-flower.—Vespertilion, or Bat's wing Passion-flower.—Red Passion flower.—Maliformous, or apple-fruited Passion-flower.—Silky Passion-flower.—Multiflorous Passion-flower.—Quadrangular Passion-flower.—Suberosous, or Cork-barked Passion-flower. (*Woody, and Herbaceous climbers.*)

PERIPLOCA, Virginia Silk, &c.—Indian *Periploca*. (*Woody.*)

PHOENIX, Great Palm, or Date-tree. (*Ligneous.*)

PHYSALIS, Winter-cherry.—*Arborescent*, or Tree *Physalis*.—Winter-cherry of *Gurassao*. (*Woody.*)

PLUMBAGO, Lead-wort.—Ceylon *Plumbago*.—Rose *Plumbago*. (*Ligneous or Undershrubby.*)

PLUMERIA, Red Jasmine.—Red *Plumeria*.—White *Plumeria*.—Obtuse *Plumeria*. (*Woody Succulents.*)

POINCIANA, Barbadoes Flower-fence, &c.—Fair *Poinciana*, or Double-spined Barbadoes Flower-fence.—Bijugated Single-spined *Poinciana*.—Spineless *Poinciana*.—(*Shrubby.*)

POLYANTHES, Tuberose, or Indian Tuberous Hyacinth. (*Herbaceous.*)

PTELEA, Shrub trefoil.—Viscous Indian *Ptelea*. (*Shrubby.*)

RHAMNUS, Buckthorn.—*Spina Christa*, or Ethiopian Jujube.—*Oenoplia*, or Ceylon Jujube. (*Shrubby.*)

RHUS, Sumach.—Cobbe, or Ceylon Sumach. (*Shrubby.*)

RIVINIA, Dwarf Tetrandrous *Rivinia*.—Climbing Octandrous *Rivinia*. (*Ligneous.*)

ROBINIA, False Acacia.—Violet American *Robinia*.—Smooth Indian *Robinia*. (*Tree and Shrub kinds.*)

SACCHARUM, Sugar-cane.—Common Sugar-cane.—Spiked Sugar-cane. (*Herbaceous, of the Arundinaceous tribe.*)

SCHINUS, Indian Mastic-tree.—Molletree of Clusius, or Peruvian Mastic-tree.—Areira, or Brazilian Mastic-tree. (*Woody.*)

SIDEROXYLON, Iron-wood.—Inormous, or Smooth Ethiopian *Sideroxylon*.—Spinous, Malabar *Sideroxylon*. (*Shrubby.*)

SOLANUM, Nightshade.—Guinea Nightshade.—Fiery-thorned Nightshade.—Bahama Nightshade.—Trilobate Nightshade, &c. (*Shrubby.*)

STAPELIA, Variegated *Stapelia*.—Hairy *Stapelia*. (*Succulent, and ligneous.*)

TAMARINDUS, Tamarind-tree. (*Tree.*)

THEOBROMA, Chocolate nut-tree.—Cacao, or Chocolate-nut-tree.—Guazuma, or Bastard Cedar of Jamaica. (*Shrub and Tree kind.*)

TOLUIFERA, Balsam of Tolu-tree.

TOURNEFORTIA, Shrubby *Tournefortia*.—Volubilate, or Twining *Tournefortia*.—Fœtid, or Stinking *Tournefortia*.—Hairy *Tournefortia*.—Serrated *Tournefortia*.—Cymose *Tournefortia*. (*Shrubby.*)

TRIUMFETTA, Lappula, or *Triumfetta*. (*Ligneous.*)

TURNERIA, Elm-leaved. (*Ligneous.*)

VINCA, Periwinkle.—Rose Periwinkle of Madagascar. (*Shrubby.*)

VITIS, Vine.—Indian wild Vine.—Trifoliate Indian Vine. (*Shrubby.*)

VOLKAMERIA, Prickly *Volkameria*.—Unarmed or Smooth *Volkameria*. (*Shrubby, and Undershrubby.*)

URENA, Angular-leaved *Urena*.—Sinuated *Urena*.—Procumbent *Urena*. (*Woody.*)

WALTHERIA, American *Waltheria*.—Indian *Waltheria*.—Narrow-leaved *Waltheria*. (*Ligneous.*)

WINTERANIA, (*Shrubby.*)

XIMENIA, American Prickly *Ximenia*.—Unarmed Jamaica *Ximenia*. (*Trees.*)

ZAMIA,

ZAMIA, Dwarf American Palm. (*Fron-
dose.*)

Of the above list of Stove plants, a few of the sorts are also inserted in the green-house list; because, in default of a Stove, they may be preserved tolerably well in a good green-house, though probably brought to greater perfection in a Stove, as is generally noticed in the culture of the respective sorts, each in its proper genus.

General Management.

As to the general management of the bark Stove and culture of the plants; the pit of the Stove must always be filled with bark to produce a continual heat, making fires only in winter, &c. and all the plants must be kept constantly in pots, in order to move to different situations in the house occasionally, some in the bark-bed, others on the shelves, top of the flues, &c.

But to prepare the Stove for the reception of the plants, the bark-bed must be formed by filling the pit with new tanner's bark early in autumn, or any time else when the most convenient to obtain the plants.

The bark for this purpose is procured from the tan-yards, after having been used in tanning, and cast out of the tan-pits; chusing that which is fresh, not having lain long to exhaust itself, or become black and earthy; but the fresher it is from the tan-pits the better, preferring the larger or middling sort to the small-cut bark, which soon becomes earthy and declines its fermentation; but the larger sort will retain its heat several months: having however obtained the proper quantity, it is proper, previous to committing it to the pit, to spread it abroad or dispose it in small heaps or ridges, two or three days in dry weather, to drain and dry moderately; or if copiously wet, may afterwards be formed into an heap to drain off the redundant moisture more effectually, and promote its fermentation; and in a few days, or perhaps a week or more, it will be in good preparation for use; then fill it into the bark-pit, being careful as it is thrown in, to shake it up well together with the bark fork equally in every part, not beating or treading it down, raising the whole half a foot above the top of the pit to allow for settling, suffering it to settle gradually of itself; and thus the fermentation will come on regularly perhaps in a week or ten days; though may probably be a fortnight or more, before it becomes of a due temperature for the re-

ception of the plants: having some long sticks thrust into the bed, drawing them up daily, and feel them with the hand, you will more easily discover the progress of the fermentation, and proper degree of heat; observing, if the heat should prove violent, to defer plunging the plants till it is become of a more moderate temperature.

When therefore the bark-bed is ready, prepare to plunge the plants, such as pines and other exotics that require the aid of the bark-bed; and the other less tender kinds, to be placed in different parts of the house as their nature may require; all the sorts being previously planted in pots.

In potting the different kinds, allot proper sized pots according to the size and nature of the plants, not too large at first, for as they advance in growth they may be shifted into others, a size larger, &c.

Being careful also, to pot them in proper earth adapted to the nature of the respective sorts; though most of the shrubby or woody kinds, and the common herbaceous tribe, succeed in any common rich light earth; but all the succulent plants should be planted in a dry, sandy, or rubbishy soil, on account of their humid quality: however, as to the different soils requisite for any particular sort, it is exhibited in their culture under their respective heads.

In proceeding to plunge the pines and other sorts intended in the bark-bed, it is proper to have a broad plank or board to lay across the bed, on which to stand or kneel without treading the bark hard; likewise a hand-fork for opening the apertures more expeditiously to plunge the pots, which may be plunged to their rims, if the fermentation is not too violent; arranging the plants regularly in respect to their different gradation of height, the tallest behind, gradually down to the lowest in front; and if disposed in the quincunx way, they will receive the advantage of more room, and benefit of the air and rays of the sun more equally, plunging the whole down to the rims of the pots, as above observed; and at the same time, let all the other less tender kinds, be disposed in different parts of the house, as their temperature may require: many of the woody and herbaceous kinds succeed well enough any where within the Stove; but most of the succulent tribe succeed best in the driest part near the flues, distant from moisture, especially in winter, being;

being placed either on the top of the flues, or on shelves ranged above them; though almost any sorts of Stove plants when intended to forward them faster in growth, or into bloom, may be plunged in the bark-bed occasionally; however, as to the *ananas* or pine-apple, although they will grow in any part within the Stove out of the bark-bed, yet never so prosperously, nor produce any but small trifling fruit, therefore require to be continued always plunged in the bark-bed the year round; several other of the more tender curious exotics, not succulents, are also the most prosperous if plunged in the bark-bed, where there is room enough without incommoding the pine-plants.

Observe, if after the plants are plunged in the bark-bed, the bark should happen to heat violently, it is proper to draw up the pots half way, or far enough to save the roots of the plants from being by vehemence of the heat damaged, replunging them again down to their rims when the heat becomes more moderate.

Most of these kinds of Stove plants require to be continued almost constantly in the Stove the year round; though, if the Stove is much crowded, some of the less tender kinds will bear to be almost fully exposed to the open air, six weeks or two months in the heat of summer, in warm dry seasons; at least, may remove some into the green-house or under frames, &c. towards the latter end of June, or beginning of July, to thin the Stove; the green-house being then vacant, and in which these hardier Stove plants may enjoy the free air more copiously to promote strength, by opening all the windows daily, yet be sheltered on nights and bad weather; which would change the colour of their leaves disagreeably; removing them however, into the Stove again early in September, or as soon as the nights prove cold.

The Stove must always be kept nearly to a certain regular temperature of heat as marked on the botanical thermometer (*ananas*); observing, that in summer from April or May until October, the bark-bed heat alone, aided by the heat of the sun through the glasses, will sufficiently warm the internal air: but from October or beginning of November, to April or May aforesaid, the additional assistance of fire-heat is requisite to expel the cold within, and support a due warmth in the internal air, nearly equal to that in summer; by making fires

every evening and morning in the furnace of the flues, also occasionally on days in very cold damp weather, and rigorous frosts without sun.

But, as a guide to regulate the degree of heat requisite for Stoves, especially in winter, a botanical thermometer should be placed in a convenient situation within, not too near the fire-place or flues, but hung up towards the center of the house with the back to the sun, so as the mercury or liquid spirit in the glass globe and tube may be affected, only by the warmth of the air internally, thereby discovering the real degree of heat more effectually, which should always be so regulated, as not to exceed five or ten degrees over or under the mark *ananas*, which as we noticed before, is the standard generally to be observed in regulating the temperature of Stove heat at all seasons.—See THERMOMETER.

Fresh air must be admitted into the Stove occasionally at all seasons, for the benefit of the plants in general, by sliding some of the front or top glasses open in sunny days, more or less, according to the season and temperature of the outward air. &c. observing, however, that in winter and early spring, air must be admitted but sparingly and cautiously, only at favourable opportunities in fine calm sunny days, opening only some of the glasses a little way in the heat of the day, for two, three, or four hours, as the weather permits, shutting all close timeously in the afternoon or sooner, if the air changes cloudy or very cold; but in summer admit air more freely every warm day, and in hot sun-shine weather especially, should slide every other light open pretty considerably, and in the greatest heat of summer, may open some of the glasses almost at large towards noon: being however careful at all seasons, to proportion the admission of free airy, judiciously, both as to time and quantity; not opening too soon in the day, before the sun has some power of heat; that in winter or during the cold season, may give air in calm sunny days from about ten or eleven of the forenoon, till two or thereabout, or not so long if the weather changes; and in summer, from eight, nine, or ten in the morning, till three or four in the afternoon, or an hour or more earlier and later in very hot weather; remarking in general, that in giving air at all times of the year, to slide the lights open only a little at first
in

in the morning, and as the heat increases, towards noon admit a larger portion of air, according to the season; but when the sun or heat of the day is on the decline, shut the glasses closer in proportion, having also particular attention to shut all quite close in due time, at the approach of the weather proving unfavourable, more especially in winter, &c. and always in due time in the afternoon, before the warmth of the enclosed air falls too much below its due standard; generally observing the degree of heat on the thermometer.

Watering the plants in Stoves is also a material branch of culture to be performed, according as the different sorts require, which must always be applied more seldom and sparing in winter than in summer; remarking, the woody or shrubby plants, and most of the herbaceous tribe that are not succulent, require water frequently; the woody kinds require it the most frequent, the herbaceous plants in a middling degree, and the succulents the least of all; so that the woody and common herbaceous plants, in this department, require watering, some perhaps two or three times a week in summer; and in winter, probably not above once a week; but you will regulate this accordingly, as you observe the plants stand in need: and always apply the necessary waterings with due moderation, just to preserve the earth in the pots moderately moist, but never too wet; giving also at times occasional waterings all over the heads of the plants, in summer particularly, though but very sparingly in winter, especially to the *ananas*, *aloes*, and other exotics of similar growth; as the water would lodge long between the leaves of these sorts, at this season: nor must it be practised to the pines when in flower. But as to the succulent tribe, they being naturally very replete with moisture, need but very little water at any season, more particularly in winter; except such as stand so near the hot flues that the soil in the pots dry very fast, when a light watering now and then will be eligible, also in hot sunny weather in summer.

But in watering such of the woody plants, &c. as are apt to contract filth or insects, it is proper to water also all over their branches and leaves occasionally, at almost any season when the case requires it.

For the purpose of watering these plants, in winter particularly, a cistern or tub placed in one corner of the Stove, would be con-

venient to contain water some hours previous to the using it, just to take off the chilling cold.

Likewise, for the convenience of watering the pines and other plants plunged in the bark-bed, or where they are crowded close, a tin pipe made with two or three joints or pieces, to join into one another to lengthen or shorten at pleasure; one of the pieces having a funnel fixed at one end, so that by pouring the water into the funnel, may conduct it to any pot in the bark-bed, &c. without wetting the hearts of the plants, which in the pines is to be avoided as much as possible in winter, and when they are beginning to shew fruit.

The bark-bed will support a good growing heat three or four months, and if in that time the heat is much decreased, the pots being taken up, and the bark then forked over to the bottom, breaking all lumps, and mixing the parts well together, immediately replunging the pots, the bed will renew its fermentation, and continue in a proper temperature of heat six weeks, or two months longer, or more. Then about March or April, its strength being considerably exhausted, and probably have become earthy towards the top and sides, then prepare to revive its declining heat by the addition of about one third at least, of fresh tan, previously removing the pots, then clearing out all the most earthy or crumbly old tan at top, and outsides of the bed; then in its stead introduce as much new, as will fill up the pit again, and then fork up the whole, new and old together, plunging the pots again as before; and thus the new bark will promote a fresh fermentation, and renew the heat so effectually, as to continue it in good order till autumn; at which time, about September or October, as the bark will be in a manner quite exhausted, both in substance and its fermenting property, it should be almost entirely renewed with a fresh quantity of new tan; but previous to this augmentation, observing if the old tan is not entirely wasted to a small earthy substance, it may be skreened, to separate the small exhausted materials from the larger unexhausted bark, clearing out all the small stuff that passes through the skreen, the larger remaining in the pit; then add to this, as much fresh bark as will fill up the pit to the top, forking up the whole, new and old together; though if the whole of

the old tan is become very small and earthy, it should be cleared entirely out, and fill the pit wholly of new bark.

But for more particulars respecting these bark hot-beds, see BARK BEDS.

And as to fire-heat for the Stove, this is required only in winter and spring, as before observed, to expel the cold and damps, and support the heat of the internal air in a due temperature, as the bark-bed heat alone is not sufficient in winter; generally beginning to make the fires moderately in the end of October, or beginning of November, when cold or dark foggy weather commences, making gentle fires every night; and as the cold increases towards Christmas, encrease the strength of the fires in moderation; and in very severe, or cold damp foggy weather, continue the fires also occasionally on days, being always cautious never to make them too violent, but so as to produce nearly a uniform heat in the internal air, as marked on the thermometer; and thus continue the aid of fire-heat till about April or May, according to the temperature of the weather.

The firing for the Stoves, may be either coal, wood, peat, or turf; but where coal can be easily obtained at a moderate expence, I should prefer it for general use, as being the most steady, regular, and durable fuel, requiring less attendance than any other; but in default of this, wood, peat, or turf is used in many places.

In winter, when the frost happens to prove very severe, it is adviseable to cover the glasses of the Stove every night, at top particularly, to protect the plants; either with shutters, canvas, or tarpaulin rollers, or large garden-mats, &c. as formerly mentioned, which covering may also be used in the day-time occasionally, if the frost continues extremely rigorous and no sun appears; but by no means continue the day-covering to darken the plants longer than it shall appear absolutely necessary.

And in the heat of summer in very hot sunny days, it may sometimes be proper to afford the plants a moderate shade of mats, over the top glasses for an hour or two, during the violent heat, lest the sun shining vehemently through the glasses should scorch the leaves or burn them in holes, and prove detrimental to small tender plants.

Shifting the plants into larger pots, and fresh earth occasionally, must also be duly attended to.

Accordingly therefore, as the different plants in the Stove encrease in growth, and require larger pots, they should be shifted into others a size larger; which may be requisite to some plants annually, such as the pine-apples and other free-growing exotics; others once in two years, and some not so often; such as some of the smaller slow-growing succulents, &c. though most sorts of plants in this department will either require shifting, or fresh earthing more or less every year or two; either in the same or larger pots, as their growth may require.

The general season for performing these works of shifting or fresh-earthing, is either in the spring about April or May, or early part of autumn, as August or the beginning of September will be time enough for the plants to strike fresh root in the newly added earth before winter; though if any particular plant stand in great need of shifting, or is in a bad state of growth, the shifting may be performed almost at any season of the year, chusing however principally the spring or autumn as abovementioned for any general shifting.

In performing the shifting, generally preserve the ball of earth entire about the roots, unless the roots are supposed to be in a decayed state, when all the old earth may be cleared away, and the roots trimmed as occasion require; but those removed with the entire ball, should only have any very mouldy and matted roots round the sides and bottom of the ball trimmed off, together with a little of the old earth, if it can be done without disturbing the ball; then having the new pots and fresh compost ready, placing pieces of tyle or oyster-shell over the holes in the pots, and some fresh earth at bottom, set in the plant and fill up round the ball or roots with more new mould almost to the top of the pot, giving directly a moderate watering to settle the earth close; and thus proceed plant and plant till finished, returning each to its proper place again; plunging all the pines in the bark-bed, and also as many of the other plants as room will admit, which will forward their striking or rooting more quickly in the new earth: after which the less tender kinds may be removed to the shelves, &c. in any part of the Stove.

Such plants however, as do not require shifting annually, may be fresh earthed at top, &c. in spring; previously removing some of the old earth from the top, and a little way

way down round the sides of the pot, then replenishing with an equal portion of fresh mould, will prove very beneficial culture, finishing each with a very moderate watering to settle the earth.

It is of importance in the Stove culture to keep all the plants clear from decayed leaves, by removing all such as soon as they appear, as it both tends to preserve the beauty and health of the plants.

Likewise, it is of consequence to keep all plants confined in Stoves clean from dust and filth, which most sorts are apt to contract by such confinement, often to their great prejudice if not timely cleaned; this may sometimes be effected in some sorts, by now and then watering the plants all over their heads, which will wash off any loose dust, and give the plants a lively healthful appearance; though, where any is very foul, is adviseable to wash the leaves thereof, leaf and leaf, with a sponge and warm water, especially the larger or broad-leaved sorts that admit of it, also the stems and branches wheresoever any filth is contracted; but as to the pines in particular, and the *aloe* kinds, and others of the like growth, should not be watered all over in winter, because in that season the water is apt to lodge between their leaves a long time, so should only wash their leaves when foul with a wet sponge tied on the end of a small stick, for cleanliness contributes exceedingly to the prosperity of the plants; dust or any filth being suffered to encrease considerably, is apt to clog and obstruct the fine necessary organs of perspiration, as well as the absorbent vessels destined to imbibe the humidity of the air; thereby cause a stagnation of the sap, and the plants assume a sickly state, and often become the prey of insects: it is therefore effectually necessary to keep all these plants as clean as possible, as it certainly conduces very considerably to their health and beauty.

Insects often infest the plants in Stoves, and sometimes prove very destructive to some sorts, particularly the pine-apple; appearing first like mildew, and soon after assume the appearance of lice. The causes of them are variously assigned; some impute it to uncleanliness and bad state of health, others to the dry air of the Stove, unavoidably occasioned by the fire-heat, and others to the bad

management of the plants; though it is certain we shall often also see plants that are seemingly healthful and well managed, suddenly attacked with insects; and when this happens, the plants soon assume a sickly appearance. As however this disaster of insects is ascribed to several causes, so are several methods proposed for the abolition of them; some wash them with the infusion of tobacco, &c. i. e. water impregnated with tobacco stalks, tobacco dust, and foot, &c. and with this wash the leaves, stalks, and branches; and sometimes also, strew tobacco dust over the leaves and other parts: others try the effect of fumigation of tobacco, by means of a pair of bellows, furnished with a large tin or brass tube to screw on the nozzle of the bellows at pleasure, the extreme end terminating in a long pipe, and the tube being filled with tobacco set on fire, then by blowing the bellows it produces a strong stream of smoke from the pipe, which being directed to the parts of the plants infested with the vermin, it generally extirpates them pretty effectually, without injuring the plants: various remedies are occasionally advertised in the newspapers for sale, both of a powder and liquid kind, to destroy these Stove insects; also receipts to be sold for preparing such a composition, pretending to be of infallible efficacy.

However, previous to the application of the above remedies to destroy the insects, it is also of importance to keep the plants always clean from filth; the bark-bed always of a lively growing warmth, to continue the plants in a free growth, and keep the earth in the pots of a middling degree of moistness by due moderate waterings, sprinkling the tops also now and then as before observed; those however of the pines only in summer, for the reasons before given; applying also if needful, any of the other remedies that may be thought the most efficacious. Likewise, if after all, any particular plant remains severely attacked, and rendered of a very sickly, weak state by the vermin, it is adviseable to shift it into a new pot and some fresh earth, and plunge it into the warmest part of the bark-bed, or other good hot-bed under glasses, still using also the other means; and thus the plant will likely assume a free growth, and recover its proper health and vigour.

Thus far is principally the general management of a Stove, and culture of the plants at large; and as to the method of propagating the various sorts, and of any peculiar culture and other occurrences of particular species, &c. we refer to their respective genera for explanations on those heads.

A list of hardy plants, &c. for forcing in Stoves, and general culture.

As we have already observed, that besides the tender exotics which require the constant aid of the Stove, many hardy plants, both herbaceous, shrub, and tree kinds, may be occasionally introduced into the Stove, in order for forcing to early perfection when required.

For instance, various hardy herbaceous flower-plants may be forwarded into bloom in the Stove, long before their natural season in the open ground; such as early dwarf tulips, hyacinths, polyanthus;—narcissus, jonquils, and many other narcissus kinds; anemones, ranunculus, and almost any other of the more curious sorts of bulbous and tuberous flower-plants that may be required early in bloom; previously planting the roots in pots in autumn, and place them in a garden frame, &c. to be sheltered only from frost till the time arrives for placing them in the Stove, which may be almost any time in winter, though if not till towards Christmas or after, we may expect a stronger and finer bloom; placing them upon shelves towards the glasses: or if required to have some of them flower as early as possible, may plunge the pots into the bark-bed; supplying all the sorts duly with water, especially after they begin to shoot; and they will here grow freely without trouble, and produce their flowers both early, and in very good perfection.

Likewise pots of pinks, carnations, sweet-williams, wall-flowers, stock-gilliflowers, &c. being placed in the Stove in January, February, or any of the early spring months, may be forwarded considerably in flowering; also many other fibrous-rooted perennials, that may be required early in flower. Likewise in the Stove may be raised many of the curious annual flowers early from seed, and forwarded to an early bloom.

Of esculent herbaceous plants, may raise early kidney beans and cucumbers in great perfection in the Stove; the seed, &c. being

planted in pots or boxes of rich dry earth any time in winter or early spring, placing those of the kidney-beans any where in the house, and the cucumbers near the top glasses upon shelves, just over the back walk and flues; may also raise small fallading any time in winter, sown in boxes or large pots, &c. likewise strawberries, the plants being trained in the open ground in the garden to a bearing state, either the Alpine or scarlet sort, (see FRAGARIA) and being then potted with balls of earth about their roots early in autumn, or even in winter whilst the weather continues open; and placed in the Stove near the glasses any time from January till March, either all at once, or at different times for succession, they will produce plenty of fine strawberries. I have also forced excellent early asparagus in the Stove, when there has happened to be a vacancy in the bark-bed to admit of plunging the plants in the tan, as directed in forcing them by dung hot-beds, under the article ASPARAGUS.

As to flowering shrubs, if an early bloom is required, they may be forwarded considerably in the Stove; such as roses, honeysuckles, jasmines, and various other principal sorts that have merit in the beauty or fragrancy of their flowers; the plants being previously potted, may be placed in the Stove in winter, or any time from January till February or March, &c. either in a common pine-apple Stove, or a forcing Stove, they will flower freely a long time before their natural season.

And as to the fruit-tree kinds, several sorts may be fruited very early in the forcing Stove particularly, especially most of the stone fruits, and some of the berry kinds; such as cherries, peaches, nectarines, apricots, plums, grapes, and figs; also gooseberries, currants, raspberries, &c. all of which being previously trained in the open ground to a bearing state, then planted in the Stove; or some in pots to move to the Stove occasionally, beginning to force them any time in January, or early in February; some being planted finally in the ground or border of earth formed within the Forcing-Stove; others in pots, particularly some of the dwarf cherries, and smaller fruit shrubs; but the peaches, nectarines, apricots, plums, vines, and figs, should generally be planted against a trellis erected near the back and front, to be

be trained as wall trees; also some of the early May and duke cherries; tho' cherries generally succeed very well in standards, both full and half standards, and dwarfs; pruning them generally to moderate heads, that they may not become high or spreading, to interfere with each other, or shade the other trees too much. Vines also in particular, may likewise be planted in the open ground against the outside of the front of the Stove, and their stems trained in through holes made in the wall or timber framing; and the branches within trained up thinly against the slope and end sashes, &c. to slight trellis work fixed to the bearers, so as the sashes have full liberty to slide; observing such vines as are thus trained in from the outside of the Stove, should in winter when severe frosts prevail, have that part of their stems without, defended by a close wrapping of hay-bands; also the ground over their roots, especially towards spring, when the vines begin to shoot within of the Stove.

Remarking, as to the time to begin forcing by fire-heat the above hardy plants and fruit-trees, that, if in a forcing Stove for the purpose, January or beginning of February is the proper season; then shut all the glasses close, except giving air occasionally as hereafter hinted; making the fires moderate at first, encreasing their strength gradually, though always in a moderate degree, never above the temperature of the pine-apple standard, continuing the fires every night and morning in the above moderate manner; also occasionally in the day time, in severe frosts or cold damp weather. If, however, there is only a common pine-apple Stove for general use, you should generally have all your plants intended for forcing planted in pots, &c. in order that they may be moved into the Stove only at the proper season; or, to have a regular succession, may introduce them at two or three different times, at a fortnight or three or four weeks interval, having plants, &c. for this purpose ready potted, and in winter placed under occasional shelter from frost, till placed in the Stove.—All the plants thus forced in the Stove must be allowed the benefit of fresh air in fine days, and occasional waterings; as to fresh air, if in a common pine-apple Stove they can only enjoy the advantage of air in common with the other plants in that department, as directed in the culture of Stove

plants: but if they are in a forcing Stove by themselves, fresh air may sometimes be admitted more freely, especially after the plants have begun to shoot; chusing, however, only fine mild sunny days for this, by sliding open the lights a little in the heat of the day; encreasing the portion of air as the warm season advances, shutting all close towards evening: and as to water, all the plants, both herbaceous kinds, shrubs, and trees, will require occasional moderate waterings; those in pots will require it more frequent than such as are planted fully in the ground: chusing generally warm sunny weather for this work, especially in winter and early spring; and give it always in due moderation.

As soon as these forced hardy plants are past perfection, either as to flowering or fruiting, &c. those of them you intend preserving for future use, and that are in pots, should be moved into the open air, to recover themselves, as some of them may serve for the open ground, and some also to force again after having a summer's growth in the full air, especially the shrub and tree kinds; and as to such as are planted in the full ground in forcing Stoves, should, as soon as the flowers and fruit are past, be fully exposed to the open air, by removing all the glasses, that they may receive the full advantage of the air, showers, dews, &c. all summer, and until nearly the arrival of next forcing season, that they may regain proper strength and vigour to yield their produce in due perfection the following year; observing towards winter, or at the approach of sharp weather, to put on the glasses again, in order to give occasional shelter till the time to begin forcing, and then the Stove must be shut up close, and managed as before.

According as any of the fruit-trees fail, or become bad bearers, let them be removed in due time, and their place supplied with new ones from the nursery.

STROBILUS, a species of seed-vessel commonly called *Cone*.

The *Strobilus* or *Cone* (*Conus*) is the fruit or seed-vessel of the coniferous or cone-bearing trees, such as pine, fir, cypress, juniper, &c. being of a conical figure, formed of a conic *amentum*, composed of scaly imbricated calices, becoming so many hard woody scales, laid over on one another like tiles, closely involving the seeds. See **CONIFERÆ** and **CONUS**.

This

This species of seed-vessel being generally of a conical form is commonly called a Cone, (*Conus*.)

STYLUS, the Style of the flower.

The Style is that long slender part of the *pistillum* placed on the top of the germen, in the center of the flower, elevating the stigma or summit of the *pistillum*, or female organ; and is corresponding to the vagina in animals, as being the tube through which the effluvia of the farina or fertilizing male dust of the antheræ emitted on the stigma, pass to the germen or seed-bud, for the impregnation of the embryo seeds. See PISTILLUM, GERMEN, and STIGMA.

Every female and hermaphrodite flower is furnished with a *pistillum*, and consist of three parts, viz. the germen, Style, and stigma; the germen supports the Style, and the Style the stigma on its summit. Thus the Style connects the germen and stigma; and in plants apparently without, or with but a very short Style, the stigma is placed on the germen; as in *papaver*. The number of Styles vary in the plants of different genera, the greater number having only one Style, others two, three, to five, ten, or many Styles, which in each flower is generally equal in number to that of the germen or seed-bud, each germen being furnished with its own particular Style; so that flowers having but one germen have generally but one Style; and those with two, three or many germens, have the like number of Styles. There are, however, some exceptions, as there are plants which have more than one Style for a single germen or seed-bud, as in the umbelliferous tribe; others on the contrary have a single Style common to many seed-buds, as in the verticillate tribe of lip flowers. And in another tribe of plants the Style is single at its origin, but soon divides or branches out into as many ramifications as there are divisions or cells in the cavity of the seed-bud, such as in the geraniums and mallow tribe, which have their Styles divided above into five branches, corresponding to the five divisions of the seed-bud or capsule.

From the number of Styles, and in their absence that of the *stigmata* is founded the orders or secondary divisions of the classes in the sexual method. See CLASSES and ORDO.

The Style in most plants is erected like a

column in the centre of the flower; in some, however, the Style is nodding or reclined, or in others is revolute or bent backwards; and sometimes as in *nigella Arvensis*, the five Styles being longer than the stamina, are first erect; afterwards when the flower is fully expanded, they are bent back, that the stigmas may touch the anthera of the stamina or male organ; and having thereby received the male dust, they are again elevated, and ever after remain erect. For the most part the Style is always surrounded by the stamina, so that some of the *pollen* or male dust of the antheræ is blown by the wind on the stigma.

As to proportion and dimension, the Style is either of equal length with the *stamina* as in most flowers; much longer, as in some others; and in some very short, or even wanting, as in *papaver*, &c. in which the stigma fits close to the germen; and in substance the Style in some plants is thicker than the *stamina*; in others of equal thickness, and in some slenderer.

As to figure, the Style is either cylindrical and hollow like a tube, as in most plants; angular, as in *cana*; awl-shaped or tapering as in *geranium*; capillary or slender like a hair; or club-shaped, being thicker above than below, as in *leucoium*, the greater snow-drop, &c.

In point of situation, the Style is situated either on the top of the germen, as in most flowers; above and below the germen, as in *cappavis* and *euphorbia*; or on one side of the germen, as in rose, raspberry, and other plants of the *icosandria polygynia*; or on the base of the germen as in *alchemilla* or ladies-mantle, &c.

In respect to duration, the Style is either deciduous, falling off with the other parts of the flower, after the impregnation, as in most plants; or sometimes permanent or abiding, as in the cruciform flowers of the *tetradynamia*.

STYRAX.

Storax, or Sweet Gum-tree.

It is a deciduous aromatic tree of the East, retained in our gardens to diversify the greenhouse and shrubbery collections; is famous for its medical gum called Storax, being a fragrant resinous fluid, which the tree imparts by incision in the trunk; the very wood also imparts a sweet odour.

Class

Class and order *Dodecandria Monogynia*.

Characters.] CALIX is short, cylindric, monophyllous, and quinque-dentate.—COROLLA is monopetalous, infundibuliforme, with a short cylindric tube, and spreading limb divided into five obtuse segments.—STAMINA, about twelve or more awl-shaped filaments, disposed circularly, having oblong erect antheræ.—PISTILLUM, a roundish germen below the corolla, single style, with a truncated stigma.—PERICARPIUM, a roundish, unilocular, drupaceous fruit, containing two roundish nuts, convex on one side.

There is but one species, which in this country generally requires the culture of hardy green-house plants, during its minor state; but when hardened by degrees to a more mature growth, it may be turned out into the full ground in a warm situation, finally to remain.

The species is,

STYRAX officinale.

Common or officinal Styrax.] Rises with a woody stem, branching on every side, twelve or fifteen feet high, or more, covered with a smooth greyish bark, oval, moderate-sized, alternate leaves, hoary underneath; and bunches of white odoriferous flowers at the sides of the branches in June; succeeded sometimes by fruit, but rarely ripens in England.

This tree is a native of Syria, and most parts of the East; where it is highly valued for its fragrant medical gum; which it exudes from the trunk and branches.

It is, although an exotic of hot countries, moderately hardy, as in this country it only requires shelter of a frame or green-house from severe frost while young, for three or four winters; afterwards may be planted in the full ground against a south wall, and other sheltered situations; training some against the wall, others take their natural growth, and allow occasional shelter of mats in very severe weather.

It is propagated commonly by seeds, obtained from abroad by the seedsmen; sowing them in pots of light earth an inch deep, observing as they are of a hard stony nature, they rarely come up the first year; so it is proper to plunge the pots under a frame during cold weather, and in the shade in summer, and in the second spring; then as the seed will be ready to germinate, if plunged in a hot-bed, it will forward them exceedingly,

being careful to give water, and to harden the seedlings gradually to the full air in summer, in a shady place during the hot weather, and often watered; and in winter place the pots under a garden-frame, &c. to have shelter from frost; then in spring following pot them off separately, and manage them as hardy green-house plants for three or four years, when some of them may be turned out unto the full ground in a sheltered situation, as already hinted, and some may be retained in pots for the green-house collection.

SUCCULENTÆ, (*Succus*, Juice) Succulent plants.

Succulent Plants are such as have thick fleshy leaves, &c. abounding with juice, being principally of the herbaceous tribe; and some become of a ligneous nature in the stem, though Succulent in leaf; and of the Succulent kind there are perennials, biennials, and annuals; but principally perennial and evergreen.

Of the Succulent tribe many are tender exotics, inhabitants of the hot parts of the world; and some are of hardy growth; are mostly inhabitants of dry barren soils, and rocky places; many of which being of singular growth, are retained in our garden collections as plants of variety and curiosity; consisting of many different genera, each comprising more or less varieties, some for the green-house and stove, and some for the open ground. The following is a list of the principal genera, and their varieties, collected into one point of view, referring to their respective articles for particulars.

AGAVE, Great Amenum Aloe. (*All the species.*)

ALETRIS, Guinea Aloe. (*All the species.*)

ALOE, African Aloe. (*All the species.*)

ANTHERICUM, Spider-wort. — Aloe-leaved. — Mock Asphodel. — *Anthericum*, Shrubby, Onion-leaved.

CACALIA, Foreign Colts-foot. — *Ficoides*, African *Cacalia*. — *Anteuphorbium*, Ethiopian *Cacalia*. — *Kleinia* or Indian *Cacalia*. — Papillary Ethiopian *Cacalia*. — (*All of somewhat shrubby growth.*)

CACTUS, Melon-thistle, including also the *Cereus* or Torch-thistle, and the *Opuntia*, or Indian Fig. (*All the species.*)

COTYLEDON, Navel-wort. (*All the species.*)

CRASSULA, Lesser Orpine. (*Most of the species.*)

EUPHOR-

S U C

EUPHORBIA, Burning thorny plant. —
(*Most of the sorts.*)

MESEMBRYANTHEMUM, Fig Marigold.
(*All the numerous sorts.*)

PORTULACA, Purslane. (*All the sorts.*)

SAXIFRAGA, Saxifrage. — Cotyledon
Saxifrage, &c.

SEDUM, Lesser Horse-Leek, Orpine, and
Stone-crop. (*Most of the sorts.*)

SEMPERVIVUM, Live-ever, or Common
House-leek. (*All the sorts.*)

TETRAGONIA. (*Both the species.*)

YUCCA, Adam's Needle. (*All the sorts.*)

ZYGOPHYLLUM, Bean-caper. (*Most of
the sorts.*)

As many of these Succulents are esteemed singular curiosities in the vegetable creation, they are cultivated as such in most of our eminent gardens; a general description of the different sorts, their propagation and culture, may be seen in the proper places, under the heads of their respective genera.

They are mostly of a very carnosose or fleshy nature, both in stem, leaves, &c. abounding with humidity, and mostly evergreen; and many of them assume great singularity in their general port or habit; and as to magnitude, some when they flower obtain thirty or forty feet stature, as the *agave Americana*; others, such as the stone-crop, &c. not above three or four inches. See each under its proper genus.

Most of the sorts being originally inhabitants of dry soils, or saxtile or rocky situations, walls, tops of old buildings, and ruins, &c. and being naturally all very replete with moisture, should therefore in their culture be mostly planted in light dry, lean earth, or dry rubbishy compost (see COMPOSTS); otherwise, on account of their great humidity, are very apt to rot off in winter, more particularly the very Succulent and tender kinds of the green-house and stove (see GREEN-HOUSE and STOVE PLANTS); and which sorts in particular are always to be kept in pots, in order to be placed among the plants of those two conservatory departments, as their nature or temperament require, and managed accordingly, as hinted under the *Culture of Green-house and Stove-Plants* afore-said: always kept from too copious moisture; for as they naturally abound in juice, they require very little water at any season; but in winter especially should have it but very seldom and sparing; and some of the most Suc-

S U C

culent hardly any water during all that season.

And as to the hardy kinds, such as the common house-leek, or pine, stone-crop, &c. (see their proper genera) will grow in the open air, on rock-work; dry rubbishy borders, tops of walls and buildings; and are proper plants to introduce in artificial ruins and rocks, &c.—May also be planted in pots to move to any place occasionally. With respect, however, to the general description, uses, propagation, and culture of this tribe of plants, we refer to their respective genera, where every thing is fully exhibited; but the principal curious sorts being only here brought under one head, serves as a hint of the nature of these kind of plants, and to assist the memory, so as more readily to furnish a collection of the different sorts.

SUCCUS, Sap, or the Juices of Plants.

The main vegetable juices or fluids are drawn by the root from the body it adheres to, whether it be earth, water, or other substance; thence ascends to the stem, branches leaves, flowers, and the minutest part of the fructification, &c. But whether the same Sap, so diffused to the extremities of the plant, ever returns, and that there is a circulation of Sap in plants analogous to that of the blood in animals, is a question, which will probably never receive a satisfactory answer.

Though many of the eminent naturalists contend for the circulation, and that the same juice descends again to the root; yet by accurate experiments it appears, that the Sap ascends not by the bark, but by the capillaries or fibres of the wood; and the curious observation of many renders it highly probable that the fluid which ascends by the said capillary vessels of the wood, descends to the root by the larger fibres of the inner bark that are most contiguous to the woody body. In support of this, the same experiments of ligature and incision which evince a circulation of the blood in animals, succeed in the like manner in vegetables, particularly in such as abound with a milky Sap; since if the ligature or bandage is fastened tight round them, the part above is found to swell very considerably, and that below it only a little, whence it appears there is a juice descending from the branches: and as to the experiment of incision, it has likewise been observed, that upon a transverse incision being made into the trunk of a tree, the juice which is

ex-

expended or flows from the wound, proceeds in greater quantities from the upper lip of the gash, where the swelling likewise is much larger than below; so that from the result of such experiments it is rendered somewhat more than probable, that the sap returns from the extremity of the branches to the root; thence into the earth again. But some contend, that instead of the same juices going and returning, there are two several juices; the one terrestrial, as being imbibed from the soil, digested in the root, and from thence transmitted to the extremity of the plant; the other is supposed to be aerial, and received from the moisture of the air entering in at the extremity of the branches, and surfaces of the leaves. So according to this conclusion, the ascending and descending juices are not the same; and indeed with respect to the aerial sap, experiments have determined that the plant derives part of its nourishment by the extreme branches, and the leaves in general, and that the leaves contribute greatly both to the abundance and motion of the sap; for it is observable of new-planted trees in particular, having many of their branches lopped, they will not prosper near so well as those trees left entire; and if a tree when high in sap is divested of its leaves, it will be found to retard the growth, both of its shooting, and that of the flowers and fruit.

However, the first and principal sap of a plant is furnished by the earth entering the roots in form of a fine and subtle water, which, the nearer it is to the root, the more it retains of its proper nature; and the farther from the root the more action it has sustained, and the nearer it approaches to the nature of the vegetable.

But what course the sap takes after it is imbibed by the roots, is not very clear; the vessels that take it up to convey it to the plant, are too fine to be traced, and hence it remains doubtful, whether it is by the bark, or the woody part, or the pith that the plant is fed.

In this the naturalists differ in opinion. Some contend for the bark, others for the wood, though in the former case they observe, that the juice raised from the earth by the capillary tubes or pores of the wood is here supposed to descend by the larger fibres placed in the inmost part of the bark immediately over the wood; in which descent the sap being now sufficiently prepared adds some of its substance to the contiguous wood, and

thereby gradually encreases its bulk, so that the bark is thus also supposed to serve divers purposes; for it not only transmits the nutritious juices to the plant, but likewise contains certain fat oily juices to defend the fleshy external parts from the injuries of the weather.

In some cases, even the whole plant is no more than bark; the pulp or woody part having been eaten or rotted out, except just the outside shell, as often occur in willow, elm, &c. yet continue growing, and live a long time in that state.

On the other hand, those who contend that the wood conveys the principal nourishment, observe, that the whole woody body consists entirely of slender longitudinal capillary tubes or fibres, running parallel to each other from the root up the trunk and branches, being proper to receive in a fine vapour or humour, in the ascent of which the fibres become open, and their substance encreased. And thus the trunks of trees are said to encrease in their circumference.

The motion of the nutritious juices of vegetables is found to be produced much like that of the blood in animals, by the action of the air, &c. for it is discovered that vegetables consist of two orders of vessels; 1. such as receive and convey the alimential juices, answering to the arteries, lacteals, veins, &c. of animals; 2. the *tracheæ*, or air-vessels, being long fine pipes or tubes possessing principally the wood or ligneous body, and serve to receive and transmit the air, necessary for preparing and giving motion to the humours or juices.

As to the nature of the vegetable fluids, it appears, that plants contain many different juices, such as those of the root, stem, bark, &c. those of the leaves, the juices of the flowers, or genitals, and those of the fruit, the preparative of the last, of which may be said to be nature's final work.

However, the principal vegetable juices are generally reduced to two; the lymph or sap; and the proper juice or blood of plants.

1. The lymph or sap is a simple fluid, being without colour or smell, and little different from water; and mounts from the root to the stem, and remote parts of the plant, as before observed, in its proper vessels, which are woody longitudinal hollow fibres, almost inconceivably fine, and always replete with sap; which, however, in spring, is found in greatest abundance, and then the bark is

easily detached from the wood. On the contrary, when the sap-season is past, the bark is found closely applied, and, as it were, glued to the wood; or when a tree is in high sap, and stripped of the leaves, the bark, in a few days, will adhere as closely to the wood as in winter.

2. The other principal fluid, denominated the proper juice or blood of plants, and analogous to the blood in animals, contained in proper vessels, called likewise from their use vegetable blood, are straight longitudinal fibres, larger than the lymphatic or sap vessels, and less numerous, which are filled with the proper juice, which is generally compound or coloured, and easily distinguished by its colour, smell, and substance, from the lymph or sap, it being either green, as in some plants, white as in spurge, fig-tree, and dog's-bane; yellow, as in celandine, red as in dragon's blood, mucilaginous or gummy, as in the jujube and mallow tribe, or resinous, as in the coniferous plants. So it is from the variety in colour and substance that the fluid in question is called the proper juice; each species of plant being supposed to contain a fluid peculiar to itself; and in this proper juice reside the smell, taste, and virtue of the plants.

SUCKERS.

Suckers are young offspring plants, arising immediately from the roots of older vegetables; and being transplanted, readily grow and become proper plants, in all respects like the mother plant that produced them, being therefore very eligible for the work of propagation.

So that Suckers may be considered as a sort of vegetable spawn or progeny, emitted from the roots of certain trees, shrubs, and other plants, to propagate their respective species and varieties: and a very considerable share of the vegetable creation multiply exceedingly by this means; for numerous sorts continue sending up great plenty of Suckers every summer, each Sucker furnished with roots or fibres, and in one season form proper plants for transplantation; thus proving a very plenteous and expeditious method of propagation both for numerous tree and shrub kinds in particular, as well as for many herbaceous vegetables; which sending up Suckers from the root in spring and summer, will be fit for transplanting the following autumn.

The propagation by Suckers is also, in cer-

tain cases, a sure method to continue any approved or intended species, or variety, the same; remarking, however, of grafted and budded trees, that Suckers partake only of the nature of the stock; as for example, such Suckers as arise from a codlin stock, grafted with any other sort of apple, will continue invariably a codlin, without partaking any thing of the nature of the graft; the same being also observable of all other grafted trees and shrub kinds; observing therefore not to mistake so far in propagating by Suckers from the roots of grafted and budded trees, worked on different stocks, to suppose the Suckers will produce the same sort of fruit, &c.

But in trees, &c. that are wholly the same sort root and top, the Suckers thereof will also prove the same invariably in every mode of growth, as certainly as is obtained by layers, cuttings, grafting, &c.

As to the season for taking up or transplanting Suckers, it may be performed almost any time in open weather from October till March, being careful to dig them up from the mother-plant with as much root or fibres as possible, and trim them ready for planting, by shortening long straggling fibres, and cutting off any thick knobbed part of the old root that may adhere to the bottom, leaving only the fibres arising from the young wood; though it is probable some will appear with hardly any fibres; but as the bottom part having been under ground, and contiguous to the root of the main plant, they will naturally be much disposed to send forth plenty of fibres for rooting. The stems of some of the shrub and tree kind particularly, will also require trimming occasionally, such as cutting off all lower laterals; and if any have long, slender, and weak tops, or such that you intend shall assume a more dwarfish or bushy growth, may be shortened at top in proportion, to from about half a foot, to one or two feet in length, according to their nature or strength, and as the case may require: others that are more robust and strong, or that you design shall run up with taller stems, may have their tops left entire, or shortened but little, as it shall seem necessary for the uses intended.

Being thus taken up and trimmed, proceed to plant them in rows in the nursery; the weak Suckers plant separately in close rows; also the shortened ones by themselves, and the stronger plants likewise separately in wider rows; so that the rows may be from one

S U C

one to two feet asunder, in proportion to the size and strength of the Suckers.

After being thus planted out in nursery rows, allow them the common nursery culture of cleaning from weeds in summer, and digging the ground between the rows in winter, &c. and in from one to two or three years; they will be arrived to due size for final transplantation.

Though some kinds of trees, &c. produce Suckers so strong in one season as to be fit for planting at once, where they are finally to remain; such for example, as some sorts of roses, and numerous other flowering shrubs; likewise some of the strong-shooting gooseberries, currants, raspberries, and the like kinds.

And sometimes many of the shrub kind in particular, having produced a quantity of Suckers from the root, and these suffered to stand and grow up, each to a large plant, the whole from one root forming a considerable bush, as may often be observed in gooseberries, currants, and many other shrubs; and in which case each such bush being taken wholly up at the proper season before mentioned, may be divided to the bottom into so many separate plants; and as each Sucker will be amply furnished with plenty of roots, and of due size for flowering and fruiting, may plant them, if required, at once, where they are always to stand.

But the propagation by Suckers is by some objected to for any general supply, on a supposition that the trees, &c. so raised, are more adapted to run too considerably to Suckers, and over-run the ground, than such as are raised by any other method: however, it may generally be observed of such trees and shrubs as are naturally disposed to send up many Suckers, that by whatsoever method they are propagated, whether by seeds, suckers, layers, cuttings, &c. they commonly still continue their natural tendency to multiply by Suckers in the same abundance.

However, when it is required to have any sorts produce as few Suckers as possible, not to over-run the ground, or disfigure the plants, it is proper both at the time of separating the Suckers, or planting them off from the main plant, and at the time of their final removal from the nursery, to observe if at the bottom part they shew any tendency to emit Suckers, by the appearance of prominent buds, should rub all such off as close as possible, which

S U N

will prevent the production of Suckers proportionably.

As, however, many sorts of trees and shrubs are subject to throw out Suckers, considerably more than may be wanted at all times for multiplication; and that if permitted to remain, would over-run the ground, and become unsightly, as well as prejudice the parent plants; they should therefore be always cleared away annually at least: but if not wanted for propagation, it is proper to eradicate them constantly as they are produced in spring and summer.

SUFFRUTICOSUS *Planta.*

Under-shrubby Plants.

Suffruticose Plants are a sort of ligneous or somewhat woody vegetables, that are between a shrubby and an herbaceous nature, exemplified in thyme, sage, hyssop, winter-savory, and such like plants.

SUN.

The Sun is doubtless the first mover of all vegetable motion; for as the naturalists observe, the Sun qualifies the air, which otherwise by its great frigidity would stop the whole course of nature: but by the Sun's diffusive power of light and heat, it exhilarates not only the race of mankind, &c. but the vegetable creation.

Its genial chearful rays promotes the growth of all vegetables, by its influence upon the soils; warming and chearing the pores of the earth, when diluted and sodden with too much wet, and puts the fibres of plants in motion for seeking their food; and its influential power operates on the branches, leaves, and fruit.

Plants, therefore, which in their growth are more or less exposed to the Sun, are, for the most part, more prosperous, forwarder, and attain greater perfection than such as grow in any considerable shade.

Likewise most fruits in a sunny exposure are considerably more beautiful, sooner ripe, and acquire superior quality in flavour, &c. to those growing in shady places.

The Sun's attractive power is very conspicuous in the exhalation or dispelling of those crude and unwholesome vapours with which the earth is so often infested, which would otherwise make it noxious, and render the earth a miserable desert: but more particularly the Sun warms, and enriches the soil, and prepares the juices for being sucked in by the fibres of plants.

For this reason, ground designed to be fallow, should always be turned up in rough ridges, to give free access to the influence of the sun and air. Likewise all compost heaps should generally be prepared in sunny situations, in the full air, not in bye shady corners, or in sheds, as often practised.

SYMPHYTUM, Comfrey.

This genus of plants consists of hardy herbaceous perennials, for variety in gardens and medicinal purposes, having long fleshy roots sending up annual stalks from half a yard to two or three feet high, adorned with oval and spear-shaped leaves, and terminated by monopetalous bell-shaped flowers.

Class and Order *Pentandria Monogynia*.

Characters.] CALIX is upright, pentagonal, five-parted at the brim, and permanent. — COROLLA is one bell-shaped petal, with a very short tube, a tubular ventricose limb; divided at the brim into five obtuse reflexed segments, having the chaps or opening armed with five subulate rays connected in a cone. — STAMINA, five awl-shaped filaments, placed alternately with the rays of the chaps of the corolla, and erect acute antheræ. — PISTILLUM, four germina, supporting a filiform style, crowned with a simple stigma. — PERICARPIUM, none; four gibbous, acute pointed seeds lodged in the permanent calix.

There are but three species, one is an inhabitant of England, the other two is of foreign growth, and are all hardy plants.

The species are

¹ SYMPHYTUM officinalis.

Common officinal Comfrey] Hath long, thick, fleshy, deeply-striking roots, black without and white within; crowned with large, oval, spear-shaped, rough leaves; upright, thick, branchy, rough stalks, two or three feet high, garnished with decurrent leaves, and terminated at top by bunches of drooping flowers, of different colours in the varieties, appearing in June and July.

Varieties are] Common white flowered — purple-flowered — blue-flowered — yellow-flowered — red-flowered: but the white and purple are the most common.

It grows wild in England, especially the white-flowered sort, by ditch sides, and other humid shady situations; but is sometimes kept in gardens for variety and medical uses, the root being the useful part.

² SYMPHYTUM tuberosum.

Tubero-se-rooted German Comfrey] Hath a

root composed of many thick fleshy tubers, sending up inclined rough hairy stalks a foot and a half high, long, narrow, acute-pointed, rough, hairy leaves, alternate below, and opposite at top; and the stalks terminated by bunches of pale yellow flowers, in June and July. — Grows naturally in Germany, France, and Spain.

³ SYMPHYTUM Orientale.

Oriental Comfrey] Hath a thick fleshy root, upright rough stalks, half a yard or two feet high; oval rough leaves, on short hairy foot-stalks, and the stems terminated by drooping bunches of blue flowers, in March and April. It grows by river sides in the East, near Constantinople.

All these three species are of the herbaceous tribe, and perennial in root, but annual in leaf and stalk, which rise in spring, and produce flowers and seed the same year; the first and second sort in particular ripen plenty of seed; the other not always in perfection in England: and soon after the seed is ripe, the stalks decay.

As to their merit as garden plants, they may be employed in large herbaceous collections, to encrease the variety in the pleasure-ground; and the first sort in particular. SYMPHYTUM *Officinalis* may also be introduced in gardens as an officinal plant in medicine: all the three sorts are very hardy, and will prosper in any common soil and exposure; but delight most in shady moist places; planting those designed for variety thinly, in assemblage with other hardy perennials, and those intended for medical uses plant in beds or borders together, in rows, two feet asunder.

Method of Propagation, &c.

Their propagation is affected by seed, and by parting the roots.

By Seed. — Sow it in spring in a bed or border of common earth, and rake it in: they will soon come up plentifully, and in autumn the plants will be fit to transplant where wanted, in the manner above observed.

By parting the Roots. — This may be effected with expedition, and abundance in autumn, or early spring. Almost every bit of the root will grow, planting them either in nursery beds, or at once where they are to remain; and they will soon multiply into large plants.

SYRINGA,

SYRINGA, Lilac.

Two noted deciduous flowering shrubs compose this genus, each comprehending several elegant varieties, adorned with oval heart-shaped and spear-shaped simple leaves, and large bunches of small, monopetalous, funnel-shaped, odoriferous flowers, of a very ornamental appearance.

Class and order *Diandria Monogynia*.

Characters.] CALIX is small, monophyllous, tubulated, four-parted at the brim, and permanent. — COROLLA is monopetalous, funnel-shaped, with a long cylindrical tube, divided above into four narrow revolute segments. — STAMINA, two very short filaments, with small antheræ. — PISTILLUM, an oblong germen, slender, thread-like style, and a thick bifid stigma. — PERICARPIUM, an oblong, compressed, acuminate, bivalvous, bilocular capsule, having a single seed in each loculi, being oblong, acuminate, and with a membranaceous border.

There are only two species, which, and their varieties, are fine ornamental furniture for the shrubbery compartments. Are supposed to be natives of Persia, but have been long in the English gardens as eminent flowering shrubs.

The species are

SYRINGA *Vulgaris*.

Common Lilac] Rises with an upright shrubby stem, soon dividing into many branches, and grows fifteen or twenty feet high; garnished with oval-cordated, or heart-shaped leaves, placed opposite; and the flowers produced at the ends of the young shoots, in large, erect, conical bunches, of different colours in the varieties, appearing in May.

Varieties are] White-flowered — blue-flowered — purple-flowered, or Scotch Lilac.

This species and varieties have been long residents of our gardens, as elegant flowering shrubs, to decorate the wilderness and shrubbery clumps; are all so very hardy as to grow almost any where without trouble, exhibiting a very ornamental appearance, in the great profusion of their flowers, which also imparts a very agreeable odour.

SYRINGA *Persica*.

Persian Lilac, sometimes erroneously called Persian Jasmine] Rises with a slender shrubby stem, dividing into long, slender, flexible, brownish branches, growing five or six feet high, adorned with narrow, spear-shaped, entire leaves, placed opposite; and the young

shoots, terminated by long paniculated bunches of bluish, and other coloured flowers in the varieties; appearing the end of May, and beginning of June.

Varieties are] Common purple-flowered, — white-flowered — blue-flowered — lacinated, or cut-leaved Persian Lilac, having the leaves deeply cut into several segments. All of which varieties of this species are most delightful flowering shrubs, and their flowers have an agreeable fragrance.

Both these species of Lilac, and their varieties, are very hardy shrubs, of the deciduous tribe; and although originally inhabitants of Persia, grow freely in the open ground in any exposure, and resist the severest frosts; having been many years in the English gardens as ornamental flowering shrubs; all the sorts flowering profusely, and ornamentally, early in summer, each panicle of flowers being large and conspicuous, composed of numerous florets, or separate flowers, and continuing near three weeks in beauty, succeeded in the first species, and its varieties, by plenty of seed; but the second sort rarely ripen any in England.

As therefore these fine shrubs are so hardy, and easy of culture, they highly merit admittance into every pleasure-ground, large or small, being excellently adapted both to embellish the premises, and encrease the variety. They are raised in abundance in all the public nurseries for sale.

They may be transplanted almost any time in open weather from October to March, in any common soil and situation, and from a few plants of each sort they will soon abundantly encrease the stock by suckers, &c. and as to culture, observe of the *Syringa Vulgaris*, or common Lilac in particular, that as it generally throws out numerous suckers annually, they should be taken off accordingly, otherwise they will soon over-run the ground near them, and prevent the mother plant from flowering in due perfection.

Method of Propagation.

The propagation of both the species, and their varieties, is most easily effected by suckers, and layers; also by seed. But this first sort in particular throws out numerous suckers, and produces also plenty of ripe seed for sowing.

By

By Suckers.—Numerous suckers rise annually from the roots, though generally more abundantly from the first than second species; and by which all the sorts may be most readily propagated; taking them up any time from autumn till spring in open weather, with roots to each, and plant them in nursery-rows two feet asunder, to remain for a year or two, or till wanted for final transplantation.—See SUCKERS.

By Layers.—Layers of all the sorts will readily grow, and form proper rooted plants in one year; chusing the young pliable shoots in autumn, and lay them in the common way; they will be well rooted by autumn following, and ready for planting

off in nursery-rows; as directed for the suckers.

By Seed.—The first species, and varieties, ripen plenty of seed annually in autumn; and by which all the varieties may be raised, all of which are generally permanent, or retain their difference from seed; which should be sowed in October or November in a bed of common earth, either broadcast or in drills, and covered half an inch deep: they will come up in the spring, and in spring after the seedling plants may be set out in nursery-rows two feet asunder; and one distant in the rows, to have two or three years growth, when they will be fit for the shrubbery.

T.

TAGETES, African and French Marigold.

This genus is composed of noted herbaceous tender annuals, of the flowery tribe, for adorning the pleasure-ground in summer; they rising with large branchy stems, and full heads, two or three feet high, ornamented with pinnated leaves, and all the stems and branches crowned with large, compound, radiated flowers.

Class and order, *Syngenesia Polygamia Superflua*.

Characters.] CALIX is simple, monophyllous, pentagonous, and quinque-dent. COROLLA, is compound and radiated, consisting of numerous tubular, quinquefid, hermaphrodite florets in the disc, and ligulated female florets in the radius or circumference. —STAMINA, in the hermaphrodite florets, five very short filaments, with cylindric antheræ. —PISTILLUM, an oblong germen, filiforme style, having a bifid reflexed stigma. —PERICARPIUM, none; each floret succeeds to a single linear compressed seed, crowned by five acuminate, erect, unequal aristæ.

There are but three species of *Tagetes*, two of which only are common to England, each comprehending many varieties; all of

them tender annuals, and generally require the aid of hot-beds to raise and forward them at first, planting them out afterwards in the open ground to grow to perfection; which they attain in July and August, producing a great profusion of flowers, both singles and doubles; but the latter are considerably the most ornamental, they growing large, and full to the very centre, appearing both conspicuous and ornamental, for two or three months in autumn, having different properties in the respective varieties, in respect to plenitude, colour, and variegations; but have mostly a very disagreeable odour.

The species are,

Tagetes erecta.

Upright Mexican Tagetes, commonly called African Marigold, or African] Rises with an erect, firm, single stem, branching erectly all around near a yard high; having large pinnated, light-green leaves, of many pair of narrow lobes; and all the branches terminated by large, compound, yellow flowers, one on each peduncle, exhibiting different properties in the varieties.

Varieties are] Lemon-coloured, or pale yellow-flowered African.—Deep yellow-flowered.—Orange-coloured.—Sweet-scented.—

scented. — Dwarf, &c. — All of which varieties furnish both single and double flowers; the doubles being large, full, and swelling, rendered so by different modes of impletion, such as—Radiated doubles, rendered double by the impletion or multiplication of the plane florets of the radius.—Discous doubles, rendered full by the elongation and less profound division of the hollow florets in the disc—Fistulous, or quilled doubles, having all the florets appearing fistulous or hollow like a quill—Plane doubles, having all the florets plane or flat—Waved doubles, having all the florets waved—Common single-flowered, having plane florets in the radius, and numerous small tubular florets in the disc. See the *Characters*, and COMPOSITUS FLOS.

All these varieties being species of the *Tagetes erecta*, they rise with erect, firm stalks and branches, as in the specific description, producing numerous flowers in regular succession, from June or July until October, succeeded by abundance of seed in autumn.

²TAGETES *patula*.

Spreading Mexican Tagetes, commonly called French Marigold] Rises with subdivided spreading stalks and branches, two feet high, large pinnated deep-green leaves, and at the sides and ends of the branches numerous, moderately large, compound, radiated flowers, yellow, crimson, and variegated, in the different varieties.

Varieties are] Pale yellow-flowered. — Deep yellow-flowered — Golden yellow-flowered — Crimson-coloured. — Variegated crimson and yellow, consisting of many beautiful variegations in different varieties. — Striped, crimson, and yellow. — And of each of which colours there are Single-flowered. Double-flowered — Large-flowered — Small-flowered — Sweet-scented, and dwarf French Marigold. — All of which rise with subdivided stalks, of very branchy spreading growth, producing a great profusion of flowers from the sides and ends of the branches, in succession, from June or July, until November; but the double, the variegated, and the striped sorts, are the most beautiful; likewise some of the variegated and striped singles are remarkably elegant in their variegations, and richness of colours; all the sorts producing great plenty of ripe seed in autumn.

Both these species of *Tagetes*, and all their numerous varieties, are herbaceous annuals, rising from seed in spring, obtain full growth

in July, flower and produce seed in autumn, and wholly perish, root and top, in October or November.

They being natives of Mexico, are consequently of somewhat tender quality here; but have been long residents of the European gardens, as ornamental flowery plants; raising them annually from seed in spring, generally in a hot-bed; thence planted into the full ground, &c. in May or June, where they flourish in great perfection, till killed by the frost.

The flowers of both the species and respective varieties, are large, and very conspicuous; but those of the first species, *Tagetes erecta*, are much the largest: and in all the sorts they are universally compound and radiated, each flower being composed of numerous smaller ones, all within one general calix or cup; which, in their characteristic, or common single state, the middle or disc consists of many small tubular, hermaphrodite florets, and of many plane or flat tongue-shaped female florets forming the circumference or radius: but in their multiplied state, they are rendered double by different impletions; sometimes by the tubular florets of the disc being enlarged, lengthened, and less divided at the brim; and sometimes the impletion is effected by an encrease of the flat florets, in the ray or radius, multiplying inward, and fill the disc, to the total exclusion of the tubular florets; and in some varieties the impletion consists wholly of plane florets; in others, they become wholly fistular or quilled, as often obtain in some varieties of the first species *Tagetes erecta*.

The different variation of each of these two species, although apt to vary one to the other, that with particular care in saving the seed of each respective sort, from the very finest full flowers and best colours, will remain tolerably permanent, and mostly produce the like kind of flowers in return.

All the sorts, considered as ornamental plants, are eligible furniture for decorating the borders, and other conspicuous compartments of the pleasure-ground; also to plant in pots for moving occasionally, to adorn any particular compartment, in assemblage with other potted annuals: they will all grow freely in any common soil of a garden, and in an open exposure; and exhibit a very conspicuous autumnal bloom, in long succession; and being properly disposed in assemblage, will affect a very ornamental variety in

in the diversity of the various forms and colourings of the flowers, in the different varieties.

They therefore being all of the annual tribe, as we already observed, that being raised from seed sowed annually in the spring, about March or April, in a hot-bed, or warm border, &c. as hereafter directed; they will arrive to a proper size for planting out towards the middle or latter end of May, or beginning of June, when the weather will have become settled or temperate enough to admit of their being planted any where in the full ground, finally to remain to produce flowers and seed.

They are all of very free growth, especially after being planted out finally in the full ground, where they require but very little culture.

The first species in particular, and varieties, as they always grow firmly erect, both in stem and branches, require but very little trouble after their final transplantation.

But the second sort *Tagetes patula*, divides and spreads out wildly near the ground in a rambling manner; it requires to be trimmed up at bottom to a single stem, and its branches also trimmed occasionally, to preserve the head somewhat regular, and within due bounds.

Method of Propagation.

As to the method of propagation, they are raised only from seed sowed every spring in March or April, either in a hot-bed, to raise the plants to more early perfection, or in a warm border, about the middle or latter end of April, for a later bloom.

By a Hot-bed.—Towards the middle or latter end of March, or beginning of April, you may sow some seed of each sort in any moderate hot-bed either alone, or with other annuals of similar temperament, such as China aster, common balsamine, marvel of Peru, chrysanthemum, &c. See ANNUAL PLANTS. Having therefore a hot-bed ready, and sheltered with a frame and lights, or with hand-glasses, &c. or in default of either, arched over with hoops, to be covered with mats on nights, which will succeed tolerably, if not sowed before the beginning of April, observing, in either method, the hot-bed being properly earthed at top, five or six inches deep; then sow the seed of each species and respective variety separate, either in shallow drills a quarter of an inch deep, or on the surface, and covered with light mould

that depth; or may be sown in pots, and plunged in the hot-bed.

They will soon come up, giving occasional waterings, and admit a large portion of free air to strengthen the plants as they advance; which when about from three to four or five inches high, prick a quantity of the best upon another moderate hot-bed four or five inches asunder, to have about three weeks growth or more to forward them as much as possible: assisting them with proper waterings, giving likewise occasional shade from the sun till rooted, and plenty of free air daily; another parcel of the same seedlings may, about the beginning or towards the middle of May, when the weather is settled tolerably warm, be planted out into the full ground, taking opportunity of showery weather; and plant them either at once where they are to remain, or in nursery-beds, in rows half a foot at least asunder; being careful to give water directly, repeating it occasionally in dry weather, together with occasional shade, where convenient, in sunny days, till the plants are well rooted afresh. And when those thus pricked out both in the hot-bed, and in the nursery beds in the open ground, have had three or four weeks growth, or till from six or eight to ten or twelve inches high, they may be transplanted with balls of earth, without hardly any check by their removal; or if permitted to stand till they shew bloom sufficient to discover which are double and which single-flowered, and then chusing only the best sorts accordingly, removing them with a ball of earth about their roots as aforesaid, into the borders and pots, or other places intended, at from five at least to ten feet distance from one another, and distribute the different sorts so as to effect diversity, watering them directly, and at times till fresh rooted.

Or, if intended to plant the whole immediately out from the seed-bed into the borders, &c. finally to remain, as often practised to save time and trouble; and that if you would cultivate only the finest sorts, may plant two or three plants nearly close together in patches, about the borders, the afore mentioned distance, or in pots, &c. and as soon as they shew their flowers large enough to judge of their properties, may clear away the worst, and leave only one of the best sorts in each patch, or pot.

Likewise, when intended to plant any in pots, to adorn fore courts, &c. always the very

very best doubles of the finest colours, from among those which have been previously pricked out in nursery-beds, and remained to shew bloom, transplanting them with balls of earth into the pots, giving plenty of water, and place them in the shade till they have taken good root; then remove the pots of plants where wanted.

Raising them in the open ground.—In default of hot-beds, &c. may raise all the varieties of these plants in the full ground, but the seed must not be sowed before April, and chiefly towards the middle of that month; chusing some warm rich border, sow the seed either in shallow drills near half an inch deep, or all over the surface, and covered thinly with earth, or raked in evenly; observing, that if the place is defended with any spare hand-glasses, or frames and lights, or even with hoop-arches for the support of mats, it will be of much advantage in affording shelter in cold nights; however, this sowing often succeeds tolerably well without any covering, though probably not come so forward as those that have occasional shelter.

When the plants thus raised are from about three to five or six inches high, as formerly noticed in the hot-bed culture, they should be planted out either finally into the borders, or in nursery-beds for a little time; then transplanted where they are to remain, as before directed.

As to future culture of all these plants, after being finally planted out, give occasional waterings the first week or fortnight till they have taken root, as before advised; and after being advanced in growth, place some stakes where needful to the strongest large-headed plants, one stake to each; likewise trim off low straggling branches near the bottom, and long ramblers of the top or head just to preserve a little regularity, more particularly in the *Tagetes patula*, which is apt to ramble considerably.

Those planted in pots will require constant watering, three times a week at least, or even every morning or evening in very dry hot weather.

Saving Seed of all the Sorts.

As to saving the seed of these plants, they ripen abundance in September; but it should be collected only from the finest double flowers, to preserve the respective varieties

in as true perfection as possible, which, without this precaution, are apt to degenerate considerably; therefore gather only the prime large heads of seed; which, after being spread to dry properly, may either be beat or rubbed out, or retained in the heads; putting the whole up in bags or boxes till spring, for sowing.

Always save fresh seeds every year; for those more than one year old rarely grow.

TAMARINDUS.

Tamarind tree.

It is a large tree of Indian growth, adorned with fine pinnated leaves, and bunches of tripetalous flowers; and is retained here in our stoves for variety.

Class and order, *Triandria Monogynia*.

Characters.] CALIX, four plane, oval, acute leaves, coloured and deciduous.—COROLLA, three oval, plicated, equal, rising, spreading petals, the length of the calix, with room for a fourth and lowest petal, &c.—STAMINA, three awl-shaped, rising filaments in the sinus of the calix, arched towards the corolla, and with oval incumbent antheræ.—PISTILLUM, an oblong, pedicelated germen, awl-shaped rising style, and thickish stigma.—PERICARPIUM, a long, compressed, unilocular pod, having a double bark, and contains generally three angular seeds.

There is but one species, viz.

TAMARINDUS *Indica*.

Indian Tamarind-tree.] Rises with a large trunk, dividing into a very branchy spreading head, growing fifty or sixty feet high, covered with a brown bark; long abruptly-pinnated leaves of sixteen or eighteen pair of oval lobes, not terminated by an odd one; and at the axillas of the leaves loose bunches of reddish flowers, succeeded by seed-pods full of an acid pulp, surrounding the seeds; but do not ripen in England.

The seed-pods of this tree are the tamarinds used in medicine, &c. being of a pulpy acid nature, excellent to quench thirst, and allay heat; and are imported hither from the West and East Indies, preserved in sugar.

This tree is a native of the East and West-Indies, also of Ægypt and Arabia; and from which countries it was first introduced into the European gardens for variety; where it requires the constant protection of a stove all the year; so must be kept always in pots, and continued constantly in that department, and

managed as the other woody exotics of the stove collection.

It is propagated by seeds obtained from abroad, which sow in spring, in pots of light earth, and plunged in a hot-bed or bark-bed in the Stove, &c. where they will readily come up, and when the seedlings are three or four inches high, prick them out in separate small pots, giving water and plunge them again in the hot-bed, repeating the waterings, and give occasional shade from the sun till fresh rooted: and as the plants advance in growth, shift them into larger pots, and keep them always in the bark-stove.

TAMARIX.

Tamarisk-tree.

Consists of two hardy deciduous tree and shrub kinds, for variety in the shrubbery compartments, garnished with narrow finely-divided leaves, and numerous small pentapetalous flowers in loose spikes at the ends of the branches.

Class and order, *Pentandria Trigynia*.

Characters.] CALIX is obtuse, divided into five obtuse erect segments, and permanent.—COROLLA, five oval, concave, spreading petals.—STAMINA, five or ten capillary filaments, having roundish antheræ.—PISTILLUM, an acuminate germen, no style, but three oblong feathery revolute stigmas.—PERICARPIUM, an oblong, acuminate triquetrous, trivalved, unilocular capsule, having numerous small downy seeds.

There are only two species, the one somewhat of the tree kind, the other a shrub, both deciduous hardy exotics, and remarkable for one producing pentandrous, and the other decandrous flowers; and both of which are very ornamental.

The species are,

TAMARIX *Gallica*.

Gallican or French Tamarisk.] Grows fourteen or sixteen feet high, with slender spreading irregular branches, covered with reddish and brown bark, narrow finely-divided leaves, having the indentures imbricated, or lie over one another like scales of fish, and numerous small, pale-red, pentandrous flowers in loose spikes at the ends of the branches.

TAMARIX *Germanica*.

German Tamarisk.] Grows eight or ten feet high, branching erectly, covered with a yellowish bark, small, divided, scaly, light-green leaves, and numerous, larger decandrous flowers in loose spikes at the ends of the branches.

Both these species of *Tamarix* begin flowering in July, and as they are produced numerously towards the ends of all the branches in large loose spikes, they appear very conspicuous and ornamental; for though the flowers are separately small, they are very numerous, and closely placed in each spike; and which in the first species have each but five stamina, (*pentandria*), and in the second species ten stamina, (*decandria*), each flower succeeded by oblong three-cornered capsules, full of downy seed, rarely ripening in England.

These shrubs are proper ornaments for decorating the shrubbery, and all hardy deciduous plantations; as they exhibit a very conspicuous variety, both in their beautiful foliage, and fine spikes of flowers.

They will succeed in almost any soil and situation; and may be had at the public nurseries; and being in possession of a few, may soon encrease them plenteously as below.

Method of Propagation.

They are propagated the most readily by cuttings; also occasionally by layers; though they generally grow very freely by cuttings.

By Cuttings.—They will readily grow by cuttings of the young shoots; and the proper season for planting them is almost any time from October till February or March, in open weather; chusing therefore a quantity of cuttings, young shoots of the year, and plant them in a shady border, or any moist ground, in rows a foot asunder, they will be well rooted by the following autumn; when, if necessary, they may be transplanted in wider rows, and in two or three years they will be ready for the shrubbery.

By Layers.—The young shoots are the proper parts to lay, and the autumn or early part of winter is the season for laying them; which perform by slit-laying, and let them remain a year; then examine them, and plant off such as are rooted in nursery rows till wanted.

They may also be raised from seed sowed in a moist border as soon as it can be obtained.

TAMUS.

Black Briony.

Two hardy, herbaceous, climbing perennials, compose this genus, sometimes raised for variety in the pleasure-ground, and for medical uses; are volubilate climbers, rising by

T A M

by support many feet high, garnished with heart-shaped and trifid leaves, and bunches of apetalous dioecious male and female flowers of no beauty.

Class and order *Dioecia Hexandria*.

Characters.] CALIX, male and female flowers on separate plants, the males having a six-leaved cup, and the females a monophyllous one divided into six parts. — COROLLA, no petals. — STAMINA, six simple filaments in the males, with erect antheræ. — PISTILLUM, in the female flowers, an oblong germen under the calix, cylindric style, having three reflexed emarginated stigmas. — PERICARPIUM, an oval trilocular bacca, having two globular seeds.

There are but two species, one an inhabitant of England, &c. among hedges and bushes, and the other of the island Crete; are both large fleshy-rooted plants, perennial in root, but with annual stalks.

¹TAMUS *Communis*.

Common Black Briony.] Hath a very large, thick, fleshy root, covered with a blackish brown skin; sending up long, twining, climbing stalks, winding round any support ten or twelve feet high, heart-shaped, undivided, smooth leaves; and long bunches of white flowers from the sides of the stalks, succeeded by oval red berries.

It grows wild under hedges, &c. in England, but is sometimes admitted in gardens as a climber for variety; and is esteemed of great efficacy in medicine.

²TAMUS *Cretica*.

Cretan Black Briony.] Hath a large, fleshy root, twining, climbing stalks, mounting by support ten or twelve feet high; trifid, or three-lobed leaves, and bunches of whitish flowers at the sides of the branches, succeeded by red berries.

Both the species flower in June and July; the flowers are small, and without petals; and are succeeded in the female plants by berries ripening to a red colour in August; each having two seeds. See the *Characters*.

They are both hardy perennials that are abiding in root, producing new stalks annually in spring; will grow any where in the full ground under shrubs and bushes; and a few of each sort may be introduced in the herbaceous collection for variety and observation, in thickets, woods, and wilderness plantations, among other climbers; and may

T A N

be there raised both from seed and roots, planted at once, where they are to remain near the shrubs and bushes, and suffered to run and climb over their branches, and any adjacent support.

Some may also be cultivated in any bye place for medical use, particularly the first sort, as being the most common and the most easily obtained, either the seed to sow, or roots to plant, as below.

Both the species are easily propagated by seed, and by parting the roots.

By Seed.—The berries ripen in autumn, which should be sown soon after, that they may more certainly grow the first spring. Sowing some at once where they are to remain in patches between shrubs, &c. four or five seeds in a place half an inch deep; others may be sowed in beds, either to remain, or for transplantation.

By parting the Roots.—The old roots often furnish off-sets, which should be slipped off early in autumn or spring, and planted at once where they are to remain.

TAN, or TANNER'S BARK, for making hot-beds, called bark-beds.

Tanner's Bark, commonly called simply Tan or Bark, is the Bark of the oak-tree, peeled therefrom when felled in the woods for timber, of which there are generally great falls made every spring, when all the bark is detached for the tanner's use in tanning of leather, being previously chopped or ground to pieces; and after being used for that purpose, and cast out of the tan-vats, becomes a valuable material in gardening, for making those kind of hot-beds commonly called bark-beds, which are considerably the most effectual hot-beds in use, for the culture of most kinds of tender exotics, that require aid of artificial heat in this climate all the year in stoves, &c. being generally made in an oblong pit or cavity six or eight feet wide, and three deep, the length at pleasure, (see BARK-BED and STOVE); and the hot-bed being, in substance, the same width and depth, it produces a very substantial, tho' moderate, uniform, and durable heat, not so apt as dung hot-beds to heat vehemently, and endanger burning the plants, nor send up a noxious steam; and the heat is of three times longer duration, and more easily managed; for a Bark hot-bed will support its heat near a year, with the assistance of a little fresh Bark added every three or four months,

months, forking up the old and new together each time. See BARK-BED and STOVE, &c.

Therefore this valuable material Tan or Bark for the purpose of making hot-beds, is the cast-off Tan of the tan-yards; which, however, they preserve in store with the utmost care for sale to the gardeners, who now, since stoves have become so common almost every where, fetch it far and near, which is sold at per bushel, or cart, or waggon-load; but generally about London is sold at seven and six pence per load of sixty bushels, being careful to have that which is as fresh out of the tan-vats as possible, and that of proper quality, for there are different sorts, some being chopped or ground moderately large, some middling, and some cut very small, to make it go the farther for particular purposes of tanning, though not near so proper for the gardener's purpose as the middling or larger sort; but the largest of all heats the most violently, the middling more moderate and durable, and the small sort soon becomes earthy, and declines its heat; so that the middling Tan is preferable for general use: however, as there is now such an universal demand for this article, the desired sort is not always to be readily obtained; therefore we are often obliged to put up with a mixture of all sorts.

But for the particulars respecting the choice and preparation of the Tan or Bark, and method of forming it into a hot-bed, and management thereof, see BARK-BED, BARK-PIT, FORCING-FRAME, and STOVE.

TANACETUM.

Tansey.

This genus comprises herbaceous and shrubby perennials for the kitchen-garden, pleasure-ground, and green-house collections, all of upright growth, from two or three to eight or ten feet high, garnished with bipinnated, pinnated, and entire leaves, in the different species; and the branches terminated by numerous compound flowers, in umbellate and corymbose bunches.

Class and order, *Syngenesia Polygamia Superflua*.

Characters.] CALIX, a compound flower, having a hemispherical, imbricated general cup.—COROLLA, numerous tubular, quinque-dentate, hermaphrodite florets in the disc, and trifid female florets in the radius.—STAMINA, five short capillary filaments, with cylindric antheræ, in the hermaphrodite flo-

rets.—PISTILLUM, an oblong germen, slender style, having in the hermaphrodites a bifid revolute stigma, and two reflexed stigmas in the females.—PERICARPIUM, none; a single seed in each floret, placed on the convex naked receptacle.

There are about eight species of *Tanacetum*, though not above five or six esteemed for culture in our gardens; three of which are hardy, herbaceous perennials for the full ground, and three are of shrubby growth for the green-house.

Hardy herbaceous kinds.

Under this head is comprised the common Tansey with varieties, Costmary or Alecoast, and Siberian Tansey; all hardy, fibrous-rooted perennials, abiding in root, but with stalks rising every spring and decaying in autumn.

TANACETUM Vulgare.

Common Garden Tansey.] Hath a fibrous, tough, creeping root; upright channelled stalks, branching erectly two or three feet high; large, bipinnated, cut, serrated leaves, of a strong agreeable odour; and all the stalks and branches crowned with umbels of yellow flowers in July and August.

Varieties.] Common plane-leaved Tansey. — Curled-leaved. — Variegated-leaved. — Scentless Tansey.

The common sort grows wild in England, &c. by road sides, and on the borders of fields, and sides of banks, &c. but which, and its varieties, have been long employed in our gardens, both as culinary and medical herbs; and sometimes as ornamental plants: but for the latter purpose the curled-leaved, and variegated sorts merit the most respect; the curled sort in particular having very large thick leaves, most beautifully curled, appearing double as it were, and is of a heightened grateful fragrance; which therefore, together with the variegated sort, demand a place in every ornamental collection, where they will exhibit a very conspicuous diversity.

However this herb, for its oeconomic uses in the kitchen and medicine, merits culture in every garden, the leaves being sometimes used in sallads while young and tender in the spring, and for making Tansey-cakes, puddings, &c. and the leaves, seeds, and flowers, are said to be a certain remedy to destroy worms in the human body.

This herb, therefore, merits culture in every kitchen-garden, planting slips of the root

root in beds, in rows a foot asunder, where it will abide many years.

² TANACETUM *Balsamita*.

Balsamita Major, commonly called *Costmary* or *Alecoast*.] Hath a thick, fibrated, fleshy, creeping root; upright, round, branchy stalks, a yard high; oval, entire, serrated leaves; and the stalks and branches terminated by corymbose bunches of deep-yellow flowers in August.

It is an odoriferous plant, formerly in much esteem both as a culinary and medical herb, and as such is still cultivated in some kitchen gardens, planted as the common Tansey.

³ TANACETUM *Siberica*.

Siberian Tansey.] Hath a thick, fibrous, creeping root; upright, branchy stalks, two feet high; pinnated leaves, having very narrow foliola or pinna, ending in two or three points; and at the axillas and termination of the stalks, smooth, corymbose bunches of yellow flowers, in June and July.

All these herbaceous kinds are durable in root, but annual in leaf and stalk.

Tender shrubby kinds for the green-house.

Consists of three shrubby species, mostly evergreens, originally from *Æthiopia* in *Africa*, and require the shelter of a green-house here in winter: they rise with shrubby stems and branches from three or four to eight or ten feet high; ornamented with pinnated and pinnatifid leaves, and bunches of yellow, compound flowers at the end of the branches.

⁴ TANACETUM *Suffruticosum*.

Under-shrubby Æthiopian Tansey.] Rises with under-shrubby branching stems, three or four feet high, pinnated multifid leaves, of many very narrow lobes, sub-divided into acute parts, and roundish bunches of bright yellow flowers at the ends of the branches.

⁵ TANACETUM *frutescens*,

Shrubby African Tansey.] Rises with a woody firm stem, branching six or eight feet high; pinnatifid leaves, with spear-shaped obtuse entire segments or lobes; and roundish bunches of sulphur-coloured flowers at the ends of the branches.

⁶ TANACETUM *Crithmifolium*.

Samphire-leaved Shrubby Tansey.] Rises with a shrubby stem, branching five or six feet high; pinnated leaves, with very narrow entire lobes, remote from one another, and

corymbose bunches of yellow flowers at the ends of the branches.

All these six species of *Tanacetum*, both herbaceous and shrubby kinds, flower very abundantly every summer, though not all esteemed ornamental; but the shrubby kinds in particular most of all: the flowers of all the sorts are separately smallish, but being collected into numerous large umbellate and corymbose bunches at the top of the stalks and branches, appear very conspicuous; and being compound, each separate flower is composed of many smaller ones, all within one general cup, (see the *Characters*); and are succeeded by plenty of ripe seed in autumn, more especially the herbaceous kinds.

The three herbaceous *Tanacetums* are very hardy fibrous-rooted perennials, that prosper in almost any soil and situation, and are of great duration in root, which also creeps and spreads very considerably; by which the plants, propagated abundantly, and encreasing into large bunches, require trimming or cutting in all round occasionally, to keep them within moderate bounds, especially the common Tansey, and varieties. The two first species in particular, are the most common in England, and are cultivated in kitchen-gardens as culinary herbs; but more commonly the *Tanacetum Vulgare*; planting slips of the root of each sort in autumn or spring, in rows a foot asunder. They may also be all employed to diversify the compartments of the pleasure-ground, among other large herbaceous perennials.

And as to culture of these herbaceous kinds, it consists principally of cutting down the decayed stalks annually in autumn; and as the roots encrease fast into large bunches, spreading widely round, they require trimming in, or to be slipped occasionally, which otherwise are apt to over-run the ground; keeping them clean from weeds, and dig between the plants annually, in common with other such-like perennials.

The three shrubby *Tanacetums* being exotics from hot countries in *Africa*, are somewhat tender here, but they only require shelter from frost; so must be always kept in pots, and deposited among the green-house plants, and treated like other shrubby exotics of that collection; in which they will effect a very agreeable variety at all times of the year, but more particularly all summer and

and autumn, when in flower. They generally begin flowering the early part of summer, and continue mostly till the end of autumn; but are rarely succeeded by good ripe seeds in England.

Propagation of all the sorts.

Herbaceous kinds. — All the herbaceous species are propagated plentifully by parting the roots; also by seed.

By parting the Roots. — All these sorts multiply exceedingly by the root, which is the most expeditious and ready method of propagating them; which is performed by slipping or dividing the roots into slips, in autumn or winter, when the stalks are decayed; or early in spring, before new stalks shoot forth, planting the slips at once where they are to remain: those for the kitchen-garden, such as the common Tansey, &c. plant in any bed or border a foot and a half asunder; and those intended for variety in the pleasure-ground, dispose singly here and there, at eligible distances, to effect a proper diversity.

By Seed. — Plenty of seed may be saved in autumn, which being sowed in spring following, in beds of light earth, broad-cast and raked in, they will soon come up, and in July the plants will be fit to prick out in beds, in rows a foot asunder; some to remain, and others to be transplanted in autumn, where required.

Shrubby kinds. — All the three shrubby sorts are all easily propagated by cuttings of the branches.

The cuttings may be planted any time in spring and summer, choosing the young and most robust shoots, which cut off in proportionable lengths; and if early in spring, &c. may plant them in pots of good earth, several in each, and plunge them in a hot-bed, where they will be rooted, and fit for potting off separately in six weeks; or, if in summer, the young shoots may be planted in the full ground, in a shady border, or where they may be shaded with mats from the sun; or planted in pots, and placed in the shade, or rather under a garden frame, &c. and shaded occasionally; in all of which methods giving plenty of water, they will readily take root; but those in the hot-bed will be forwardest: they however, will all be well rooted the same season, and should then be

transplanted in separate pots, then managed as other shrubby green-house plants. See GREEN-HOUSE PLANTS.

TARCHONANTHUS.

Shrubby African Flea-bane.

It is a shrubby ever-green exotic of Æthiopia, for the green-house collection; adorned with oval leaves, and compound flowers.

Class and order, *Syngenesia Polygamia Æqualis*.

Characters.] CALIX, a compound flower, having a monophyllous, top-shaped, septemfid, coloured, permanent cup. — COROLLA, the compound flower is uniform, of many funnel-shaped, quinque-dentate, hermaphrodite florets. — STAMINA, five short filaments, with cylindric antheræ longer than the corolla. — PISTILLUM, an oblong germen, a style double the length of the flower, and two gaping stigmas. — PERICARPIUM, none; a single seed in each floret, covered with down, ripening in the permanent calix.

There is but one species, viz.

TARCHONANTHUS *Camphoratus*.] Rises with an upright woody stem, branching out towards the top, ten or twelve feet high; oblong, oval, downy leaves, white underneath; and purple-violet flowers, in spikes at the ends of the branches.

It begins flowering about September, and continues a succession of flowers several months, but does not ripen seeds in England.

It is an ever-green exotic from Africa, but has been long introduced into our gardens for variety as a green-house plant, as it requires shelter in winter; must therefore be always cultivated in pots, and managed as other shrubby exotics of this collection. See GREEN-HOUSE PLANTS.

The propagation of this plant is easily effected by cuttings planted in spring or early part of summer, in pots, and plunged in a hot-bed, giving occasional shade and water; they will soon emit roots the same year, and be fit to pot off separately in two or three months. Or cuttings planted in May and June, in beds of common earth, or in pots, and shaded with mats or oiled paper shelters, or covered with hand-glasses, and shaded and watered; they will also strike root tolerably: observing in either case, that when tolerably rooted towards autumn, they should be potted off separately, and managed as the other green-house plants.

TAXUS.

TAXUS.

Yew-tree.

It is a famous hardy ever-green tree, of stately spreading growth; a native of England, and most parts of Europe; and an old inhabitant of most European gardens, both for ornamental and useful hedge-work, and detached trained figures; and is also proper for ornamental and timber plantations, in its natural growth; but has been more universally cultivated for hedges, and various detached formal devices; as it branches out numerous and close to the very bottom, having all the branches very closely garnished with small, narrow, ever-green leaves, as to render it remarkably well adapted for training into any sort of hedges, and various kinds of fancy figures, both in close hedge-work, and detached. Hence this tree was universally cultivated in great abundance for these purposes in ancient gardening.—See HEDGES, PLEASURE-GROUND, &c.

Class and order, *Dioecia Monadelphica*.

Characters.] CALIX, male and female flowers apart, on separate trees, having no calix; but a germ or bud, like a four-leaved cup.—COROLLA, no petals.—STAMINA, numerous filaments in the males, coalesce in a column below, crowned with peltated depressed antheræ, having obtuse octofid margins, and open on each side the base, discharging the farina or pollen.—PISTILLUM, in the females, an oval, acuminate germen, no style, but an acute stigma.—PERICARPIUM, a red juicy wasting berry, succeeds the female flowers, lengthened below, and globular at top, covered by a proper coat below; and includes one oval seed, prominent beyond the berry.

There are two species, but not more than one common in Europe; the other being a native of Japan, is little known in these parts.

The common sort therefore is,

TAXUS *baccata*.

Common Berry-bearing Yew-tree.] Rises with an upright trunk, and very branchy spreading head, thirty or forty feet high or more, very closely garnished with small, narrow, stiff, dark-green leaves, growing near together, and very small, apetalous, yellowish flowers, male and female, on different trees; in clusters, at the sides of the branches, suc-

ceeded by small, red, pulpy juicy berries, containing the seed, ripe in autumn.

Varieties.] With very short leaves—Broad shining-leaved — Striped, or variegated-leaved.

The Yew, in all its varieties, is of the dioecious class, bearing male and female flowers, mostly on separate trees; flowering generally in March, but makes an inconsiderable appearance, and are succeeded in the females by great plenty of ripe berries, serving as food for birds, and to sow for the work of propagation; as by the berries or seed only the tree is generally raised, effected in great abundance in a bed of common earth, as directed under the article of their *Propagation*.

This tree, and varieties, are very hardy ever-greens, whose verdure assumes a dark melancholy hue, of a malignant nature: are all hardy enough to prosper in any common soil, even often in the most barren, cold situations, as may be observed in many parts of England, where the tree grows naturally, arriving to a large size, fit to fell for timber; which being of a very hard durable nature, is valuable for many useful purposes: and it is by some affirmed, that bedsteads made of Yew, will not be approached by bugs.

But in respect, however, to its merit in gardening, it may be employed various ways as an ornamental ever-green; also as a forest tree, both for ornament and use, as before observed. Formerly it was greatly employed for hedges; and detached trained figures, in various ornamental forms, in pleasure-grounds; but now seldom used in England for these purposes, since all formal works of that nature are mostly banished our gardens, and instead thereof it is employed in its natural state, in shrubberies, and other ornamental plantations, principally of the ever-green tribe; being there permitted to assume its natural growth, in common with other rural trees and shrubs; sometimes also planted as detached standards, in extensive distant opens of grass ground, in parks and sides of hills, &c. for variety, and suffered to grow in the order of nature; likewise is very proper to be introduced as a forest tree in all timber plantations, of the ever-green kind particularly, (see FOREST-TREES and PLANTATIONS); and for hedge-work, where

where any internal hedges are required either for ornament or shelter, no tree is better calculated, or so proper in many cases, it forming the closest, even, moderate-growing hedge of any tree of the ever-green collection. It is also peculiarly calculated for training into any formal or fancy figure, both in hedge-work, and as detached objects, such as arcades, niches, bowers, pavilions, porticos, alcoves, pedestals, obelisks, pyramids, pilasters, galleries, and various other architectural devices, as well as the figures of men, beasts, and birds, as in ancient gardening before noticed; for, by reason of its branches and leaves growing exceedingly close, and shooting very moderate and regular, they may be readily trained, by clipping, into any form: and as a hedge for shelter in nursery-grounds, &c. to defend the more tender or delicate young plants, no other but a Yew hedge is so well adapted. But as an outward hedge for a fence, it is not so well calculated as a holly or hawthorn hedge. See HEDGES.

For all of the above purposes may this noted tree be most easily trained, if proceeded with in its minor growth in the nursery; that if for hedges or any fancy figures, suffer the plants to branch away immediately from the very bottom, and trim them with garden shears once or twice every summer, to form them for the purposes intended; and if designed for the shrubbery and other rural plantations, trim them up a little at bottom to a single stem, and suffer the head to branch out on all sides and top diffusively; likewise, if for larger detached standards, trim up the stems gradually to elevate them in proportion, and encourage the head to branch out, and diffuse its branches widely around according to nature.

Yew hedges, and detached fancy figures, were in so great repute formerly, when nothing but uniform, regular designs in gardening prevailed, that, in pleasure-grounds particularly, all the divisions or quarters were surrounded with these sort of hedges, &c. so as in a manner to shut out all other trees, shrubs, and flowers, from the sight of persons in the adjacent walks; which would otherwise have afforded an entertaining variety; and instead thereof nothing hardly but Yew hedges were to be seen on every side: hence many persons of taste, considering such gardens

destitute of variety and entertainment, rooted out the hedges by degrees, and laid out the gardens anew in more open rural designs, in imitation of nature, exhibiting all the various plants to open view, from the contiguous walks and lawns. So that in conformity to the prevailing rural taste, in plans or designs in gardening, hardly any Yew hedges are admitted by way of ornament, or otherwise; or even so much as a single detached Yew, trained in any uniform manner. However, sometimes, in extensive grounds, Yew hedges, and other formal Yew figures, were so judiciously arranged, and artfully trained, as to exhibit an air of ornamental grandeur at first entrance, especially where they were not too prevalent. Therefore, in pleasure-gardens of any considerable extent, some ornamental Yew hedge work, &c. might be admitted in some particular open districts, for variety, in contrast with the rural designs; though it should be introduced with great moderation and caution, sometimes forming the entrance to some elegant compartment; and sometimes the termination or boundary of others, where they may not obstruct the prospect, or shut out from sight the view of any desirable object within the garden; training them, by clipping with garden-shears once or twice every summer, some parts straight, others formed into arches, niches, pilasters, porticos, and other figures, before noticed. See HEDGES.

Likewise, detached Yews for training into various fancy figures, might be thinly distributed here and there, and formed by clipping every summer into various forms and dimensions before mentioned, to cause variety: for all of which purposes, both for formal and rural plantations, young Yew plants may be procured at all the public nursery-grounds at a moderate rate; or may be easily raised in great abundance, as hereafter directed.

But some persons reject the Yew, on account of the gloomy mournful aspect of its verdure, and poisonous quality; others again admire it for its solemn appearance, which effects a remarkably good contrast with the other more lively evergreens; and as to its baneful effects, it is certain the leaves are of a poisonous nature, as the name *Taxus*, derived from the Greek, imports; and it is said was formerly used in compounding poisons. Hence some

some authors have distinguished this tree by the name of *Taxus lethifera*, the *death-bringing Yew*; and hereby, say they, it is looked on as a symbol of mortality, and for that reason planted in church-yards to remind people of their approaching fate.—It is certain that many accidents have happened to cattle, both horses and cows, by eating the leaves of Yew, especially the clippings of Yew hedges, which, when they have lain in the sun a day or two, and half dried, some cattle, particularly cows, will sometimes eat them very greedily; so that every one ought to be remarkably careful either to burn the clippings of these trees, or put them quite out of the way of cattle, and not carelessly cast them over the wall or hedge, into lanes, highways, or on rubbish heaps, where cattle frequently come.

Young plantable Yews for all the fore mentioned purposes, may be procured at most of the public nursery grounds, at a moderate rate; or may easily raise them abundantly from seed, of a competent size, in a few years, for final transplantation; i. e. from two or three to five or six feet high; though this tree may be removed occasionally at seven or eight feet height, if required, to form an immediate high hedge, &c. for the root being remarkably fibrous, the earth adheres close in a lump, so as to admit of removing large plants readily with a ball, to the places allotted them; supplying them with due waterings.

Method of Propagation, &c.

The propagation of this tree is effected principally by seed, which ripen plentifully in autumn, and may be sowed in any bed or border in the open ground, either as soon as ripe, or in spring. It may also be propagated by layers, and cuttings.

By Seed.—It is most adviseable to raise the principal supply from seed; which if sowed in autumn it will expedite the germination so far, as some part will rise the spring following; but if not sowed till spring, they generally all remain in the ground till the second year before they come up, though if the seeds or berries are preserved in earth or sand till spring, then sowed, they will all rise together the spring after, more plentiful and regular than the autumn sowings: however, every one may suit their own convenience or inclination, in the time of sowing; and having therefore procured a due quantity of the Yew

berries, divested of the pulp or mucilage sow them in beds of light earth, either in shallow drills, or scattered over the surface of the bed, and covered near an inch deep with light mould, out of the alleys, or elsewhere. Being thus sowed, no farther care is required but keeping the beds clean from weeds, both before and after the plants come up; giving also occasional waterings in dry weather, in spring and summer, which will forward and strengthen the seedlings in their growth: continuing this care of occasional watering and weeding, let the seedlings have two years growth in the seed-bed; then in autumn or spring prepare some ground into four-feet-wide beds, and here plant them out in nursery rows, a foot asunder, to remain two, three, or four years; when some may either be planted out finally for hedges, if required; others in the nursery quarter, in rows, two or three feet asunder, and there trained for the purposes they are intended, according to the hints before given.

After growing in the nursery till they obtain from half a yard to four or five feet stature, they may be finally transplanted in autumn or spring, for their intended purposes; they will rise with a large spread of roots, and sometimes with good balls of earth; and should be planted in their allotted places, as soon after removal as possible, giving each plant a good watering.

As to future culture, those to be trained in hedges, or for any formal detached figure, must be clipped or thorn annually, once or twice in the summer, (see HEDGES); and those in shrubberies, and other rural plantations, require only some of the lower branches trimmed occasionally up to a single stem; but permit the head generally to spread agreeably to its natural mode of growth, except just reducing any considerable rambling branch, &c.

Remark, as to the striped or variegated Yews and other varieties, that continue them exactly the same, the propagation of them should generally be effected by layers, or cuttings, as they are rarely permanent by seedlings.

By Layers.—Young shoots, not more than a year or two old, being laid in spring, summer, or early in autumn, many of them will root, and in one or two years be fit for planting off into nursery lines.

T E R

By Cutting, or Slips.—In March or April, or end of August, or early in September, slip off a quantity of the one year's shoots, divest them of the lower leaves, and plant them in a shady border thick together, in small trenches, giving water at planting and afterwards occasionally, in dry hot weather; they will be well rooted in two years, fit for transplantation into wider nursery rows.

TERRACE, (from *Terra* the Earth.)

A Terrace-walk.

In gardening, a Terrace is a raised bank of earth, &c. regularly formed in an oblong manner to any length, broad enough to admit of a spacious level walk at top, and elevated somewhat considerably above the level of the general surface; having the sides uniformly sloped, and laid with grass, and the top formed into a flat or level, sufficiently broad for a grass or gravel walk, of proportionable width, as hereafter noticed; designed in gardens as a high, airy walk, to command a better prospect of the adjacent places around, both within and without side of the garden occasionally, as well as to enjoy the fresh air in summer more freely; and likewise a noble Terrace appears very ornamental in the pleasure-ground.

As to the necessary elevation or height of a Terrace-walk, it may be more or less as the situation admits, or requires, from one foot high to one or two yards; or even three or four yards or more in particular situations, and where there are plenty of stuff, either acquired or natural, for its formation; allowing breadth in proportion, from five to thirty or forty feet, and extended to any length required, or as may be convenient: for Terraces are sometimes formed on some naturally high, rising ground, to save as much trouble as possible, in bringing stuff from a distance; and is sometimes raised wholly of forced materials.

As to the proper situation in a garden for a Terrace, this may be varied as the natural situation of the place may require; though in ancient gardening Terraces were more common than at present; some designed both for ornament and grand elevated walks, as being considerably raised with noble sloping banks, having spacious walks at top for occasional walking; others being intended only as a moderately-raised walk, sometimes extending in a line from the front of the mansion, or conducted round some grand open division, &c.

T E T

Sometimes, however, a grand Terrace-walk is formed next the house, ranging either parallel to the front, or to one or both wings; or extended in a perpendicular line outward from the front of the main house to some considerable distance; and sometimes are continued both ways; the latter generally much less elevated than the former.

Sometimes also a Terrace-walk is carried round the boundary of a lawn, or other open division; others, sometimes contrived at the outer verge of the ground, or at the termination of some particular compartment.

Sometimes also a moderately elevated Terrace is carried almost all round the outward boundary of the pleasure-ground, to command a more advantageous prospect of the open country.

In respect to form, a Terrace is always broader at the base than the top, and extended lengthways to any distance required; having the sides regularly sloped, of more or less acclivity, as the width, height, and situation admit or require. Sometimes both sides are sloped, and sometimes only one side is sloped, the other perpendicular, and faced with a substantial wall, &c. or by being formed against the side of a hill, or some naturally rising ground; in either case is finished always broad enough at top to admit of a proper walk; likewise, in some naturally-elevated situations in particular, Terraces are sometimes formed one above another in two or more ranges, each having its separate side slopes, and elevated walk; in all of which the slopes are neatly laid with grass, and the walk at top is occasionally of grass or gravel.

The ascent of entrance to a Terrace-walk, is sometimes formed by an easy acclivity of a grass or gravelled slope; and sometimes by a grand flight of stone steps.

Where a naturally-rising ground, of some considerable elevation, occurs in a proper situation, or on the side of a hill, it is an eligible opportunity for forming a grand Terrace with the least expence and trouble, by not requiring the addition of so much foreign assistance in bringing earth and rubbish, as when raised entirely on a perfect level, wholly of forced earth, brought from another place for that purpose; or where there are any excavation of ground intended to form ha-has, pieces of water, &c. the excavated stuff might

might be employed in forming a Terrace, &c. where required.

In proceeding to form a garden Terrace, the base must be staked out wider than the intended width at top, for the walk, in order to admit of the ascent of slopes being moderate.

And in its formation, all the forced earth and rubbish must be well rammed from time to time as it is applied, in order to render the whole equally firm, that it may not settle out of form after being finished; the slopes of which may either be laid with turf, or sowed with grass-seed. — See GRASS.

TETRAGONIA, *Tetragonia*.

Comprehends shrubby and herbaceous succulent perennials of Africa, for the green-house collection; consisting of two species only, both of somewhat decumbent growth, with succulent stalks, garnished with small, narrow, succulent leaves, and apetalous flowers at the sides of the branches.

Class and order, *Icosandria Pentagynia*.

Characters.] CALIX, four oval, plane, deflexed, coloured, permanent leaves. — COROLLA, no petals. — STAMINA, about twenty capillary filaments, shorter than the calix, having oblong, incumbent anthera. — PISTILLUM, a roundish, quadrangular germen, under the calix, four awl-shaped, recurved styles longer than the stamina, crowned with long hoary stigmas. — PERICARPIUM, a large leathery, tetragonous, crustaceous capsule, with four longitudinal, narrow wings, or borders; and contain one quadrilocular hard seed, or nut, with oblong kernels.

The species are,

¹ TETRAGONIA *fruticosa*.

Shrubby Tetragonia.] Hath slender, ligneous, succulent, grey stalks, branching numerous, and stragglingly, four or five feet long, inclining to the ground, unless supported, and full of crystalline drops; very narrow, small, fleshy leaves, in clusters, bespangled also with pellucid glittering pimples, and greenish and yellow flowers, by two or three together, along the sides of the branches, in July and August, succeeded by large tetragonous capsules, ripening seeds in winter.

² TETRAGONIA *Herbacea*.

Herbaceous Tetragonia.] Hath a remarkably thick, fleshy root; herbaceous, weak, trailing stalks, garnished with small, oval, plane, succulent leaves, and bright yellow flowers, along the sides of the branches, in February

or March; sometimes succeeded by ripe seeds in England.

Both these species of *Tetragonia* being exotics from Æthiopia, require shelter here in winter; so must be always retained in pots, and placed among the green-house plants, and managed like other succulents of that collection; but should be always placed in the most airy part of the green-house in winter; as they only want protection from frost, either in that conservatory, a glass-case, or garden-frame; and should be but very moderately watered during that season.

They are both of procumbent growth, and unless supported, trail on the ground. The shrubby sort is durable in root, stem, and branch, garnished with leaves all the year; but the herbaceous kind often die down to the ground, wholly or in part, towards autumn, and send up new stalks again about the latter end of the same season, continuing in leaf all winter, &c.

Both the sorts are retained in most of our eminent green-houses, to encrease the variety; and as there is a singularity in their general port or habit, particularly the *Tetragonia fruticosa*, they merit admittance in every curious collection.

They are easily propagated by cuttings, and by seed.

By Cuttings. — Cuttings of the young branches may be cut off any time in summer for planting, which, as being succulent, after having lain a few days to dry up the moisture of the cut parts, may be planted either in pots, and placed under a garden-frame, and occasionally shaded, or plunged in any hot-bed to forward them. Or cuttings planted in a bed of light good earth, in the full ground, will also readily take root, allowing shade from the sun at first, and occasional waterings: they will be rooted in six weeks, or two months, fit for potting off separately, planting each in a small pot at first, and shift them into larger as they shall require.

By Seed. — Sow it in the spring in pots, and plunge them in any moderate hot-bed, which will generally bring up the plants the same year, which otherwise are apt to remain in the ground till the second spring, before they appear. When they, however, come up, inure them by degrees to the full air; and when two or three inches high, prick them separately in small pots, placed in the shade all summer, and moderately wa-

tered and managed as other green-house succulents.

TEUCRIUM, Tree Germander, including also *Polium* and *Marum*, &c.

This genus is composed of under-shrubby and herbaceous plants, for variety in the pleasure-ground, green-house, and for medicinal use, all of very moderate growth, some upright, others with trailing stalks, garnished mostly with small, simple foliage, and small, monopetalous, ringent flowers, in verticillate clusters, and spikes at the sides and ends of the branches, in the different species.

Class and order, *Didynamia Gymnospermia*.

Characters.] CALIX is monophyllous, cut half way into five acute nearly equal segments, and is persistent. — COROLLA is monopetalous, ringent, with a short cylindric tube, incurved at the top, and with the upper lip erect, and deeply cut into two parts; the lower one into three, with the middle segment largest. — STAMINA, two long and two short awl-shaped filaments, longer than the upper lip, and prominent between the segments, crowned with small anthera. — PISTILLUM, a four-parted germen, a filiformer style, and two slender stigmas. — PERICARPIUM, none; the four roundish seeds lodge in the calix.

To this genus is added the *Polium*, and *Marum*, and some other genera, each formerly considered as a distinct genus, but now arranged as species only of this genus *Teucrium*, which comprehends above thirty different species; though scarcely a quarter of that number common to our gardens, or that have any great merit for general culture, either for use or ornament; consisting of hardy, shrubby, and herbaceous perennials, for variety and ornament in the full ground; and some tender kinds for the green-house collection.

Hardy shrubby kind.

Consists of one small, shrubby plant, hardy enough to live in the full ground in a warm, dry situation.

¹ TEUCRIUM *flavum*.

Yellow shrubby Teucrium, commonly called Tree Germander] Rises with erect shrubby stalks and branches, only a foot and a half or two feet high; having small heart-shaped, obtusely-serrated, foot-stalked leaves, hoary underneath, with the floral leaves concave and entire; and numerous flowers by threes,

in whirls, along the upper part of the branches, of different colours in the varieties. *Varieties.*] Yellow-flowered — White-flowered.

This shrub is durable in root, stem, and branches, foliated most part of the year, and produces flowers ornamentally in July, succeeded by ripe seed in autumn.

It is an exotic from Spain and Italy, long since introduced into our gardens; formerly kept as a green-house plant, but now is sufficiently naturalized to this climate to succeed in the open air all the year, in a sheltered, dry situation; though it is still also proper to keep some in pots, to move under shelter of a frame, or green-house, in severe winters, by way of a reserve, in case the fully-exposed plants should be killed by the frost.

It is easily propagated by slips, or cuttings of the branches; and by seed.

By Slips, &c. — In spring or summer, slips or cuttings of the young shoots may be planted either in pots, several in each, or in a bed or border of good earth; or, to forward them as much as possible, a quantity of slips may be planted in pots in spring, and plunged in a hot-bed; observing, in either case, to give due waterings, and occasional shade from the sun till rooted; and in autumn following, they may be transplanted in nursery-rows, for a year or two, and some in pots, for occasional shelter in winter.

By Seed. — This may be sowed in April, in a bed of light earth; and they will soon come up, and be fit for planting out early in autumn following.

Hardy herbaceous kinds.

There are many herbaceous germanders; but the most material are the following perennials, all principally of the fibrous-rooted tribe, rising mostly with herbaceous stalks; both of procumbent and erect growth; seldom exceeding a foot and a half long or high; which in some are annual, and some become somewhat ligneous and abiding; are cultivated for variety and observation, and some as medical plants.

² TEUCRIUM *Scordium*.

Scordium, or Common Water Germander.] Hath creeping perennial roots, sending up many square, procumbent, or trailing stalks, branching diffusely; oblong, indented, serrated, close-sitting, opposite leaves; and small reddish

reddish flowers, generally two together, from the sides of the stalks and branches, in July and August.

This is a medicinal herb, and smells strongly of garlic.

It grows naturally in marshy places, in the isle of Ely, and other parts of England, and most parts of Europe; and sometimes admitted in gardens, in moist places, for variety, and as a medical plant.

³ TEUCRIUM *Scorodonia*.

Scorodonia, or Wood Sage.] Hath a fibrous, creeping, perennial root; upright, four-cornered stalks, a foot and a half high; heart-shaped, serrated, foot-stalked leaves; and racemous clusters of whitish flowers, from the sides of the stalk upward, ranged mostly towards one side, appearing in July.

It grows naturally in woods and thickets in England, &c.

⁴ TEUCRIUM *Chamædrys*.

Chamædrys or Smaller-creeping Germander.] Hath fibrous, very creeping, spreading roots; many four-cornered, very branchy, trailing stalks, near a foot long; oval, cuneiform, cut, crenated leaves, on short foot-stalks; and reddish flowers, growing almost in a verticillus, or whirls, round the stalk, three on each peduncle; appearing in June and July.—Is a native of Germany, France, &c.

⁵ TEUCRIUM *Canadense*.

Canada Germander.] Hath a fibrous perennial root; upright stalks, a foot and a half high; oval, lanceolate, serrated leaves; and white or reddish flowers, collected in racemous clusters, terminating the stalks, having six leaves under each verticillus, or whirl; flowering in July.

⁶ TEUCRIUM *lucidum*.

Shining Germander.] Hath a fibrous creeping, perennial root; upright, smooth, blackish green stalks, branching diffusely; oval-oblong, cut-serrated, smooth, shining-green leaves; and purple flowers by pairs, at the axillas of the stalks and branches.—Grows naturally in France and Germany.

The following are principally of the *polium* or poly kind, moderately hardy, but rather impatient of severe frost; so should also keep some in pots, to move under shelter in winter.

⁷ TEUCRIUM *Polium*.

Polium, or Common Yellow Mountain Poly.] Hath a fibrated perennial root; herbaceous, trailing, branchy stalks, prostrate on the ground; oblong, obtuse, crenated, downy,

sessile leaves; and the branches terminated by roundish heads of yellow and other coloured flowers in the varieties; appearing in June and July.

Varieties.] There are many varieties of this species, distinguished by some little variation in their growth, having all roundish heads of flowers; mostly, however, either white or yellow.

It grows naturally in Spain and Portugal, &c.

⁸ TEUCRIUM *Montanum*.

Mountain Poly, with Lavender Leaves.] Hath a fibrous, tough, ligneous root; somewhat ligneous, weak, procumbent stalks; spear-shaped entire leaves, hoary underneath; and small white flowers in a corymbus at the termination of the branches, in June and July.

⁹ TEUCRIUM *Pyreniacum*.

Pyrenean Mountain Poly.] Hath slender, trailing, somewhat ligneous, hairy stalks; wedge-shaped, and roundish crenated leaves; and flowers produced in a corymbus at the ends of the branches, of different colours in the varieties; appearing early in summer.

Varieties.] Purple-flowered—White-flowered—Variegated purple and white-flowered.

¹⁰ TEUCRIUM *Pumilum*.

Dwarf Mountain Poly.] Hath somewhat ligneous, procumbent, slender, downy stalks, lying on the ground; linear, or very narrow, plane, leaves in quadrifarious clusters; and reddish flowers, collected into small heads, terminating the branches,—in June and July.

¹¹ TEUCRIUM *Capitatum*.

Capitated Mountain Poly.] Rises with upright, somewhat ligneous, branchy stalks, a foot high; spear-shaped, crenated downy leaves; and white flowers collected into round heads at the end of the branches, standing on peduncles; appearing in June and July.

All these herbaceous *Teucriums* flower commonly in June and July; the flowers separately small, of the monopetalous ringent kind; produced generally in a sort of verticillus, or whirls, towards the upper part of the branches: in some placed at a distance, and in others in close heads or spikes; succeeded in the first three or four sorts by plenty of seed in autumn; but the others do not always ripen seeds freely in England.

They are all perennial plants, durable in root; and some of the ligneous kinds are also

also abiding in stalk, more particularly some of the *Poliums*.

All the sorts are occasionally employed in gardens for variety and observation; and may be had at most of the nurseries.

The first four or five sorts are very hardy plants, that will succeed any where in the full ground, but most prosperously in a moist situation; all of which may be propagated abundantly by slips of the roots, in autumn or winter; or of the young shoots in spring and summer; also by seeds.

But the *Polium* kinds are rather a little tender, and should therefore have generally a dry, raised, sheltered, sunny situation, as before observed; and some should also be potted for shelter in winter, under a frame, or in a green-house.

As to the method of propagating all these sorts, it is either by parting the roots, by slips of the branches, or by seeds.

The first five sorts may be propagated plentifully, either by slipping the roots, in autumn, winter, or spring; or by slips or cuttings of the young shoots in spring, or early part of summer, planted in a moist shady place; or by sowing the seeds in a bed or border of common earth in the spring.

The *Polium* kinds may likewise be raised plentifully from seed, and by slips or cuttings of the shoots in spring. The seed is generally obtained from abroad, which should be sowed in spring in a bed of light earth, a quarter of an inch deep; where the plants will soon come up, and be fit to prick out in July or August; either in nursery-rows till autumn or spring, or planted at once where they are finally to remain.—And as to the propagation by slips, it may be performed in April, chusing the most robust shoots, and plant them in an easterly border, giving occasional waterings and shade; and they will be well rooted by autumn for transplantation.

Tender shrubby kinds for the green-house collection.

Several of the shrubby kinds of *Teucrium*, being exotics of tenderer quality, require shelter here in winter of a green-house or garden-frame; so are commonly retained in pots, and placed among the green-house plants, serving to encrease the variety of that collection; and the following are the principal sorts thereof in the English gardens, being

all moderate-growing shrubby plants, closely garnished with small simple leaves, mostly of a somewhat hoary or downy nature; and flowers growing in the verticillate order.

¹² *TEUCRIUM fruticans*.

Shrubby or Spanish Tree Germander.] Rises with an upright, shrubby, hoary stalk and branches, five or six feet high; having oblong-oval entire leaves, smooth above, and hoary underneath, placed opposite on short foot-stalks; and blue flowers at the axillas of the branches, one on each peduncle; appearing great part of summer.

Variety.] With striped leaves.

¹³ *TEUCRIUM latifolium*.

Broad-leaved Spanish Tree Germander.] Rises with a shrubby downy stalk and branches, five or six feet high; having broad, rhomboid-shaped, acute, entire, hairy leaves, downy underneath; and pale-blue flowers singly at the sides of the branches; appearing most part of summer.

¹⁴ *TEUCRIUM Marum*.

Common Marum, or Syrian Mastick.] Rises with an upright shrubby stalk, and numerous slender hoary branches, from about a foot and a half to two or three feet high; having very small oval, entire leaves, pointed at both ends, hoary underneath, and placed opposite; and bright-red flowers in clusters at the ends of the branches, generally ranged on one side, having hairy cups; appearing in July and August, but rarely any seeds in England.

This is a fine aromatic, and is an old resident of our gardens, esteemed both for its aromatic property; and to effect variety, generally as a green-house plant, though it will also sometimes succeed in the full ground, if planted in a dry sheltered situation; affording it protection of mats in very severe weather.

¹⁵ *TEUCRIUM Massiliense*.

Marseilles Under-shrubby Germander.] Rises with upright, suffrutescent, or under-shrubby stalks, about a foot high; oval, cut-crenated, rough, hoary leaves; and purple flowers in erect clusters, terminating the stalks; appearing in July, succeeded by ripe seed in autumn.

All these shrubby germanders under this head (Green-house kind) are universally perennial, or durable in root, stem, and branches; and generally retain their leaves most part of the year, flowering abundantly every summer.

summer, but rarely ripen good seeds in England.

As all these green-house sorts are exotics from distant warm countries, require to be sheltered here in winter from frost; and therefore must generally be cultivated in pots, in order to be moved into a green-house or garden-frame, during the winter, and managed as other green-house shrubs, (see GREEN-HOUSE PLANTS); but some may also be planted in the full ground, in a warm dry situation, where they will often stand through our moderate winters tolerably well; but are liable to suffer by severe frost, which renders it necessary to treat the principal part generally as green-house exotics.

The propagation of all these tender shrubby kinds, is by slips, or cuttings of the young shoots of the branches in spring, and early part of summer, as directed for the first species (*Teucrium flavum*); and when rooted, plant most of them singly in pots for removing to occasional shelter in winter, and managed as before hinted; others plant in the open air, in a dry warm exposure, to take their chance.

THALICTRUM.

Meadow Rue.

This genus consists wholly of hardy, herbaceous, fibrous-rooted perennials, some of which are cultivated in gardens for variety and ornament, rise mostly with upright stalks annually, adorned with many-lobed leaves, and smallish tetrapetalous flowers, generally crowning the stalks in paniculated bunches.

Class and order, *Polyandria Polygynia*.

Characters.] CALIX, none. — COROLLA, four roundish, concave petals that soon fall off. — STAMINA, numerous compressed filaments, broadest above, and terminated by oblong erect antheræ. — PISTILLUM, numerous roundish pedicellated germina, having thickish stigmas. — PERICARPIUM, none. — Numerous oval sulcated seeds in a head.

There are twelve or fourteen species, and the most noted of which in our gardens are the following, retained in the pleasure-ground for variety; all of which have perennial roots, mostly fibrated and creeping; and send up erect herbaceous stalks annually in spring, which constantly decay to the ground in autumn.

¹ THALICTRUM flavum.

Greater Yellow Thalictrum, or Common Meadow Rue.] Hath a thick, fibrous, creeping,

yellow root; sending up several round, furrowed, leafy stalks, five or six feet high; garnished with many-lobed leaves, having most of the lobes cut into three parts; and numerous whitish flowers terminating the stalks in many paniculated bunches, standing erect.

Variety.] Montpellier yellow-flowered, called *Thalictrum Speciosum*.

This species grows wild in meadows, and other moistish places, and by river sides in England, &c. and is sometimes introduced in gardens for variety.

² THALICTRUM aquilegifolium.

Columbine-leaved Thalictrum, commonly called Feathered Columbine.] Hath a thick fibrous root; upright taper stalks, three or four feet high; large leaves composed of many lobes, much like the *aquilegia* or columbine; and numerous whitish flowers, terminating the stalks in large panicles, succeeded by straight, triangular, pendulous seeds.

Varieties.] Green-stalked, with white flowers and stamina—Purple-stalked, with purple flowers and stamina.

Is an inhabitant of Helvetia, &c. but has been long in the English gardens.

³ THALICTRUM Cornuti.

Canada Thalictrum of Cornutus.] Hath a fibrose dark-coloured root; upright, smooth, purplish stalks, three or four feet high, branching towards the top; large many-lobed leaves like those of columbine; and numerous white flowers terminating the stalks and branches, in large panicles, each flower having five petals.

⁴ THALICTRUM angustifolium.

Narrow-leaved German Thalictrum.] Hath a fibrated root; upright stalks, two or three feet high; large pinnated leaves, of many very narrow entire lobes, and numerous small whitish flowers in panicles, at the top of the stalks.

⁵ THALICTRUM tuberosum.

Tubero-se-rooted Spanish Thalictrum.] Hath a root hung with many-knobbed tubers; upright, almost naked stalks, a foot and a half high; small obtuse leaves, three-parted at the end; and largish white flowers, in roundish bunches, at the top of the stalks; each flower having five petals.

⁶ THALICTRUM minus.

Lesser Meadow Rue.] Hath small, fibrous, creeping roots; slender branching stalks, about a foot high; leaves cut into six parts; small and whitish and yellow flowers, in a nod-

nodding position, in loose panicles, at the top of the stalks.—It inhabits moist meadows and pastures in England, &c.

⁷ *THALICTRUM foetidum.*

Fœtid or Stinking Dwarf Thalictrum.] Hath a fibrous creeping root; slender, paniculated, branchy, leafy stalks, six or seven inches high; leaves composed of many small, indented foliola, having a stinking odour; and small whitish flowers in loose panicles, at the top of the stalks.—Grows naturally in the south of France, and Helvetia, &c.

⁸ *THALICTRUM Alpinum.*

Alpine Dwarf Thalictrum.] Hath a fibrous creeping root; slender, single, almost naked stalks, about six inches high; leaves having small obtuse lobes, and whitish flowers in single clusters terminated the stalks.

All these species of *Thalictrum* generally flower in June and July, except the Alpine sort, which commonly flowers in April or May; the flowers separately are small, but collected many together in paniculated bunches at top of the plants, each flower having generally four petals, and in some species five, as in their respective descriptions; and are succeeded by ripe seeds in August and September.

They are all very hardy herbaceous perennials, that will succeed in any common soil and exposure, in the full ground; though generally are the most prosperous in shady moist situations: they are esteemed, some as flowery ornamental plants, others principally as plants of variety, and botanical observation; though all the sorts may be employed to diversify the pleasure-ground in any of the open compartments, in assemblage with other herbaceous perennials; and are all easily raised from slips of the root in autumn, which will creep exceedingly, and multiply in great abundance.

But the second and third species are the sorts that are the most commonly known, esteemed, and cultivated in the English gardens as ornamental flower plants, they flowering more conspicuously than the others; though the first sort is also often admitted in eminent gardens to encrease the variety.

The propagation of all the sorts is very easily effected in abundance, by parting the roots in autumn, when the stalks decay, or in the spring before new ones shoot forth; planting the slips, the strongest where they

are to remain, and the weakest in nursery-rows, to have a summer's growth, or to remain till wanted.

Likewise by seed sowed in the spring, in a bed or border; they will soon rise, and the seedling plants will be fit to plant out towards autumn following.

THEOBROMA.

Chocolate Nut Tree, &c.

Comprises two exotic trees of the West Indies, retained here in some eminent stoves for variety; are adorned with large oblong and heart-shaped simple leaves, and small pentapetalous flowers, in bunches, at the sides of the branches.

Class and order, *Polyadelphia Pentandria.*

Characters.] *CALIX*, three oval, concave, reflexed, spreading deciduous leaves.—*COROLLA*, five concave, galeated or arched, quinquenervous petals, having each a bifid, horn-like bristle at top, and a bell-shaped nectarium of five oval-lanceolate, connected, spreading leaves.—*STAMINA*, numerous awl-shaped filaments in five bodies, terminated by so many antheræ.—*PISTILLUM*, an oval germen, awl-shaped style, and simple stigma.—*PERICARPIUM*, a woody, unequal, oblong, or roundish fruit, or nut; having many oval fleshy seeds arranged in five cells.

There are only two species, both of the tree kind, though the first is but of very moderate growth, and the second obtains some considerable stature and magnitude.

¹ *THEOBROMA Cacao.*

Cacao or Chocolate Nut Tree.] Rises with an upright, robust stem, only about half a foot thick, branching ten or twelve feet high; large, oblong, entire, opposite leaves, near a foot long, and half as broad; and numerous yellowish flowers, in bunches, from the sides of the trunk and branches; succeeded by oblong, quinquangular fruit, full of seeds, of which is made the chocolate.

This tree inhabits the hot parts of America, where it is also attentively cultivated for its fruit, to make the chocolate; being made of the kernels, which are first roasted in a pan, and reduced to powder; then worked with orange water, and formed into a paste; afterwards mixed with sugar, aromatic spices, and perfume; then formed into rolls or cakes, and exported to Europe, and other different parts of the world.

² *THEOBROMA Guazuma.*

Guazuma.

Guazuma, or Bastard Cedar of Jamaica.] Rises with an upright large trunk, branching numerously and spreading, thirty or forty feet high; oblong, heart-shaped, serrated, alternate leaves, four inches long; and numerous small yellowish flowers at the sides of the branches; succeeded by roundish, tuberculated rough fruit, containing the seed.

Both these trees being exotics from the hot parts of America, in this country require the indulgence of a stove; so must be kept always in pots, and placed in that conservatory, and managed as other woody exotics of similar quality. See STOVE PLANTS.

They are propagated by seed obtained from abroad, sowing it as soon after its arrival as possible, in pots, and plunged in a bark-bed, where they will soon come up; and when about three inches high, pot them off separately, and plunge them in the bark-bed in the stove; and manage them as other woody exotics of this department.

THERMOMETER.

An instrument resembling a weather-glass, for measuring and demonstrating by inspection the degrees of heat and cold at all seasons, and which proves of great utility in the culture of tender exotic stove plants, by serving as a guide to regulate the proper degree of heat for stoves or hot-houses, containing such plants; particularly in winter, when fire heat is used. See STOVE.

At to the construction of a botanical Thermometer for a hot-house, it consists of a long slender glass tube, or pipe, about two feet long, having a small glass ball or globe at the end; and is fixed longitudinally on a brass or wooden plate or frame, the same length, or longer, and four or five inches broad; the glass tube and ball being furnished with a quantity of coloured liquid spirit, which is affected by heat and cold so as to ascend higher or lower in the tube proportionably, a scale being marked on the frame along each side of the tube, divided into the different degrees of heat and cold; and the spirit ascending by the heat of the internal air, promoted by fire, &c. points out on the scale the proper degree of heat required, having the name of some remarkable exotic, such as the *anana*, or pine-apple, wrote on the scale as a standard mark of the requisite temperature of heat, so as when the internal heat of the stove raises the spirit to that mark,

or within five degrees over or under, is the proper temperature for the growth of the *ananas*, and all other tender plants from the hottest parts of the world; so that the fires requisite for the stove in winter, are to be made stronger or weaker, according to the direction in the Thermometer.

Thus a good Thermometer in stoves is more particularly useful in winter, during the time the fires are made in the flues for warming the air internally; it being generally hung up towards the centre of the stove, so as the warmth thereof may operate moderately and equally on every side, and discover the real temperature of the general internal heat, which should be supported always nearly equal by the aid of bark hot-beds and real fire, sufficient to raise the spirit in the tube to the mark *ananas* aforesaid, or but a little over or under.

Remarking however, the Thermometer should not only be suspended nearly towards the centre of the stove, but also out of the sun, or at least placed with its back thereto, that the glass tube and ball containing the spirit, may be shaded from the sun-shine as much as possible; and also placed at some distance from the fire place and flues, so as neither the direct rays of the sun, or heat of the fire, darting immediately on the tube and ball, may affect the operation of the enclosed liquor, and cause it to mount considerably higher than would be effected by the real general warmth of the air of the stove, and be thereby led inadvertently into an error, in supposing the internal heat to be much stronger than it really is, when probably it is not strong enough; which, if often repeated, might in time prove very prejudicial to the plants: therefore this instrument should always be judiciously placed as above, so as to be affected only by the real general warmth of the internal air; and by observing this, you may easily regulate the stove heat at all seasons to such proper temperature as is requisite for the culture of the plants before mentioned.

That therefore every stove ought to be furnished with a good botanical Thermometer, as a guide for more certainly determining at all times the necessary degree of heat; for in winter, when fires are requisite, it is easy to make them of more or less strength, as you shall see necessary, to warm the whole

inclosed air equally, to such a temperature of heat, as to mount the spirit in the Thermometer to the degree marked *ananas*, which should be well attended to, and continued always as nearly as possible to that standard, or not exceeding five or ten degrees over or under.

Or if the Thermometer should at any time discover the fire heat in winter, &c. to be considerably too strong, let the fire be immediately lessened, and open the door of the furnace to cool the flues; also, if calm mild weather, admit fresh air moderately, if it shall seem necessary, in order to reduce the heat as soon as possible, nearly to the proper standard.

Likewise in summer, in very hot sunny weather, if the internal heat of the stove appears by the Thermometer to be much too powerful in the middle of the day, it is easily reduced to the proper temperature, by sliding open the glasses to admit free air, as you shall see convenient.

THYMUS.

Thyme.

This genus furnishes the common Thyme, and several other low aromatic plants, mostly perennials of somewhat suffruticose or undershrubby growth; some valued as noted pot-herbs, others as medical plants, and some for variety in the pleasure-ground; rising with slender stalks and branches, from about half a foot to a foot or eighteen inches high; adorned with very small leaves, and small ringent flowers in verticillate spikes and heads, terminating the branches.

Class and order, *Didynamia Gymnospermia*.

Characters.] CALIX is monophyllous, tubular, bilabiated, and permanent; having the chaps hairy and closed, with the upper lip broad, plane, erect, and tridented, and with the lower one ending in two equal bristles.—COROLLA, a small ringent petal, having the upper lip short, erect, obtuse, and emarginated, and the under one long, broad, and tridented, with the middle segment the longest.—STAMINA, two long and two short filaments, having small antheræ.—PISTILLUM, a four-parted germen filiforme style, and a bifid, acute stigma.—PERICARPIUM, none; four small roundish seeds lodged in the permanent calix.

There are seven or eight different species of *Thymus*, and of which the following are the

most material sorts for general culture; consisting of the common Thyme of our kitchen gardens,—*Serpyllum*, or Wild Thyme,—Mastic Thyme, &c. each comprising some varieties, and are all low, frutiscent perennials, mostly of very branchy bushy growth, and durable in root, stem, and branches, and all hardy enough to grow freely in the full ground, in any common soil of a garden.

¹ THYMUS *Vulgaris*.

Common Garden Thyme.] Hath very fibrey roots; erect, slender ligneous stems, of very branchy and bushy growth, a foot high, closely garnished with small oval revolute leaves, and all the branches terminated by numerous small, whitish purple flowers, in verticillate spikes, appearing in summer, and succeeded by abundance of ripe seed early in autumn.

Varieties.] Broad-leaved — Narrow-leaved — Variegated or striped-leaved.

It is an inhabitant of rocky places in France and Spain, &c. but all the varieties have been long residents of our kitchen-gardens as eminent aromatic pot-herbs, and as medical plants; also occasionally in the pleasure-ground for variety, and sometimes as edgings to beds and borders, on account of its close bushy growth; but its principal estimation is for kitchen and medicinal uses.

² THYMUS *Serpyllum*.

Serpyllum, Creeping Wild Thyme, or Mother of Thyme.] Hath decumbent creeping stalks, six or eight inches long, or more; garnished with obtuse, plane leaves, ciliated at the base, and the branches terminated by numerous small, purplish flowers, growing in heads, appearing in summer, succeeded by plenty of ripe seeds in autumn.

Varieties.] Broad-leaved.—Narrow-leaved Broad hairy-leaved — Variegated-leaved — Citron-scented, commonly called Lemon Thyme—Greater purple-flowered.

This species inhabits pastures, heaths, and commons, in most parts of Britain, and other parts of Europe; and is admitted into many gardens for variety, more particularly the variegated sort, and that called Lemon Thyme, which are sometimes disposed singly about the borders, &c. and sometimes in pots; and were also formerly employed to form edgings; but the Lemon Thyme in particular is in high estimation for its agreeable odour.

³ THYMUS *Mastichina*.

Mastic-

Mastichina, or Mastich Thyme.] Rises with slender ligneous stalks and branches, a foot long, or more; garnished with oval, obtuse, hoary leaves; and the branches terminated by the flowers in verticillate, downy heads, appearing in June, but rarely succeeded by seeds in England.

Varieties.] White-flowered—Red-flowered.

It is a native of rocky places in Spain, but is an old inhabitant of our gardens, chiefly as a finely-scented aromatic, and for variety.

⁴ THYMUS *Zygis*.

Zygis, or Shrubby narrow-leaved Spanish Thyme.] Rises with low, under-shrubby, erect stalks; long, very narrow leaves, ciliated at the base; and flowers terminating the branches in verticillate spikes.

⁵ THYMUS *cephalotos*.

Large headed Portugal Thyme.] Rises with low ligneous stalks, and stiff hoary branches, half a foot long; spear-shaped hoary leaves, placed opposite; and many whitish flowers, terminating the branches in large imbricated heads, having oval bracteal leaves.

Variety.] With small flowery heads.

All these five species of *Thymus*, and their varieties, are of an aromatic quality, and their chief virtue resides in the leaves, which impart a very agreeable aromatic fragrance. But the first three species are the most noted sorts in the English gardens; though the *Thymus Vulgaris*, or Common Thyme, is considerably the most generally known and cultivated, chiefly for its superior aromatic property, for culinary purposes.

They are universally perennial, somewhat between a shrubby and an herbaceous nature, wholly abiding in root and top, generally of somewhat bushy growth; their leaves in general very small, but closely placed, and mostly evergreen: the flowers also are very small, monopetalous, and ringent, and collected numerously in whirled, either forming spikes or close heads, each flower succeeded by four seeds lodged in the calix. See the *Characters*; and by seeds all the species may be raised, as also by slips and cuttings; and by these latter methods only, the varieties are with certainty continued.

As to the use in gardens of these aromatics, the Common Thyme is in universal estimation as a pot-herb for various culinary purposes; and being easy of propagation and culture, merits a place in every kitchen-gar-

den: which also, together with the other sorts, and their varieties, might be introduced in the pleasure-ground, in assemblage with other small frutiscent plants, to embellish the front of raised shrubby clumps, and sloping banks, &c. placing them detached or singly, to form little bushy tufts; likewise some plants of the variegated sorts, and of the Lemon Thyme, may also be potted, in order to move occasionally to any particular compartment, and under occasional shelter in very severe winters, to preserve the sorts.

But as to the *Common Thyme*, designed for kitchen use, it should be cultivated in beds, or borders, in rows, half a foot asunder at least; either the seed sowed where the plants are to remain, or young seedling plants previously raised for planting out; or slips of old plants detached with roots, which being planted the above distance, they will soon increase into bushy plants, proper to gather for use; or may be occasionally planted as an edging in the herbary, &c. and in either method the plants will prove abiding, and multiply exceedingly by off-sets; and by which the plants may be propagated at pleasure, by slipping them as above, when wanted for increase; though it is also adviseable to raise a quantity of plants every year or two from seed, as the young seedlings possess a stronger aromatic quality than the older plants: and in market gardens, where large quantities are required for sale, should always raise a due supply annually from seed, as practised by the London gardeners; which being sowed in spring in a bed of light earth, either broad-cast and raked in, or in shallow drills, as directed below, they soon come up, and the plants want thinning in June, to six inches distance, and will be fit for use the following autumn and winter, &c.

In gathering Thyme for use, in private gardens it may be cut or slipped a little at a time, as it is wanted, not stumped too close; but when intended for market, the London gardeners generally pull it up root and all, especially the seedling plants, which remain in the bed where raised, and so raise a fresh crop from seed annually.

Method of propagating all the sorts.

All the species of *Thymus* may be easily raised from seed, and by slipping the roots and branches, and by cuttings thereof.

By Seed.—All the sorts may be raised plenteously from seed; though it is rarely practised to any but the first sort, Common Thyme; and March or early in April is the proper season for sowing it; chusing any light rich, dry ground; which let be properly digged, and the surface moderately smoothed with the spade, because the seed is very small, and should not be sowed too thick, nor covered too deep; this observed, let the seed be sowed whilst the ground is fresh stirred, sowing it either broad-cast on the surface, and rake it in lightly, or sow it in flat shallow drills, and earth it over thinly in proportion: it will soon germinate, and the plants will appear in two or three weeks, being careful to keep them well weeded, and give occasional light waterings in dry weather; and thus by June they will require thinning, to six or eight inches distance; when, if required, those thinned out may be planted in another place, in rows, six or eight inches asunder, giving water till fresh rooted, observing to keep the whole clean from weeds by occasional hoeing between them in dry days, which will also stir the surface of the earth, and thereby much improve the growth of the plants; and they will arrive to good perfection early in autumn.

Remark, in respect to the varieties, that there is no depending on raising them the same from seed; therefore, when intending to propagate any particular varieties, and continue them the same with certainty, it can only be effected by slips and cuttings as below.

By Slips.—All the sorts multiply exceedingly both by slips of the root and of the branches; the rooted slips are the most expeditious method, for the old plants encrease considerably into many off-set stems, rising immediately from the root, each furnished with fibres; and that by taking up the old plants in the spring, &c. and slip or divide them into as many separate slips as you can, with roots to each, and plant them in beds of good earth, in rows half a foot asunder, giving water directly, and repeat it occasionally in dry weather till they have taken root, and begin to shoot at top; and thus they will soon grow freely, and form good bushy plants in two or three months.

But slips also of the branches without roots, will likewise succeed, if planted, any time

from March or April until about Midsummer; observing to slip off a quantity of the stoutest young outside shoots, of moderate length, and plant them in a shady border, in rows four or five inches distance, giving due waterings; they will soon emit roots, and become good plants by autumn, when they may be transplanted to where they are to remain.

By Cuttings.—Cuttings of the young branches grow readily the same as slips thereof, there being no other difference, than that the cuttings are the young shoots cut off with a knife, and the slips are slipped off from the side of the branches with the hand only; so that the propagating them by cuttings may be performed any time in spring, or early part of summer, planting them in a shady place, and duly watered, they will readily take root, and grow.

Observe, as before suggested, the propagation by slips or cuttings is also the only method by which the respective varieties of the different species are with certainty continued the same, as the plants thus raised will be in every respect similar to the parent.

THYRSUS.

A Thyse.

One of the modes of inflorescence, or manner of flowering, of the aggregate kind; being many flowers collected in a bunch, or sort of close panicle, of an oval or egg-shaped form, having the lower foot-stalks, which are longer, extend horizontally, whilst the upper ones are shorter, and mount vertically, as in lilac and horse chesnut, &c.

THUYA.

Arbor Vitæ, or Tree of Life.

This genus furnishes beautiful hardy evergreen trees, of the coniferous tribe, for adorning the shrubbery, and other hardy plantations, being of erect tall growth, very branchy to the bottom; closely garnished with very small imbricated leaves, and small apetalous male and female flowers separately on the same tree.

Class and order, MONOECIA *Monadelphica*.

Characters.] CALIX, male and female flowers apart on the same plant; the males being collected in an oblong, oval amentum, growing opposite on the common foot-stalk, the florets having an oval concave scale for the cup; and the female flowers form an oval cone,

cone, having a scale for a cup to every two florets. — COROLLA, small florets, without any petals. — STAMINA, four very small, monadelphous filaments in the males, having the antheræ adhering to the base of the calicinal scale. — PISTILLUM, in the females a very small germen, slender style, and single stigma. — PERICARPIUM, an oblong oval cone, opening longitudinally, composed of nearly equal scales, convex on the outside, and obtuse, each having an oblong seed, surrounded with a membranous wing.

There are three species of *Thuya*, two of which only are common to the English gardens, being esteemed fine ornamental evergreens of the tree kind; and which, although exotics, the one principally from America, the other from China, are hardy enough to flourish here in almost any common soil and exposure, and remain in verdure the year round; are therefore in great estimation for all ornamental plantations.

They are both of the very small-leaved kind, with the leaves imbricated, or lying over one another like scales.

The species are,

¹ *THUYA Occidentalis*.

Occidental, or Common American Arbor Vitæ.] Rises with a large upright strait trunk, branching on every side irregularly, forty feet high or more, with the branches growing somewhat horizontally and straggling; being closely garnished with very small leaves, placed imbricatim, or over each other, appearing of a dark dusky-green colour; and with male and female flowers apart, at the sides of the young branches in spring, succeeded in the females by smooth cones, having smooth obtuse scales, containing oblong seeds.

Varieties.] Common American Arbor Vitæ — American sweet-scented — Variegated-leaved.

This tree grows naturally in Canada, in North America, and in Siberia, is of an aromatic and resinous nature; the leaves emit a strong odour; also the wood, which is likewise remarkably durable: hence it is said the tree anciently derived the name *Arbor Vitæ*, or Tree of Life.

² *THUYA Orientalis*.

Oriental, or Chinese Arbor Vitæ.] Grows with a straight upright stem, branching exactly, close, and regular, thirty or forty feet

high, very closely garnished with very small flat leaves, placed imbricatim, appearing always of a bright-green colour; and male and female flowers separately at the sides of the young branches in spring, succeeded by rugged cones, composed of acute-pointed reflexed scales, having ripe seeds in autumn, or towards spring.

Both these trees are natives of distant countries, the first being of North America and Siberia, as before observed, and the other a native of China, inhabitants of humid soils, where they arrive to a considerable stature and magnitude; and from which countries they were many years since introduced into the European gardens, as ornamental trees in the pleasure-ground; being hardy enough to succeed in the open air all the year, in any common soil and situation, and thrive as in their native climate; and are all easily raised from seed, layers, and cuttings, as hereafter directed.

They, in their general growth, assume a picturesque ornamental appearance, being finely branched to the very bottom, always fully adorned with leaves, which are universally of a very minute size, but very closely and curiously arranged in an imbricated manner, exhibiting a perpetual verdure: on the whole, the trees effect a very distinguishable variety at all seasons.

And as to their flowering, they flower early in the spring; but the flowers being small and apetalous (without petals), they are not ornamental; are universally monoecious, or male and female, separated on the same tree; consisting wholly of scaly calixes, containing the fructifications, collected into oblong and conic bunches; the males being in oblong amentums, and the females in close oval cones, which become that sort of seed-vessel called a cone, furnishing ripe seed in autumn, or towards spring. — See CONIFERÆ and CONUS.

The first sort, *Common American Arbor Vitæ*, is the oldest resident in our gardens, very distinguishable from the other by the dark-green colour of its leaves; which, however, in winter particularly, assume a disagreeable dusky hue.

But the *Chinese Arbor Vitæ* is both of more regular growth, and its foliage continued always of a fine lively green, summer and winter.

T H U

ter, and is generally a more beautiful tree than the other.

However, both the sorts are in high estimation, as fine ornamental evergreens, and most elegant furniture for adorning the shrubbery, and all other garden-plantations, designed for variety and ornament; have also a fine effect, disposed singly in the open spaces of grass ground, in the shrubbery or wilderness; in all of which situations, suffering them generally to grow rural, nearly in their own natural way, except reducing with a knife any very straggling or rambling branches occasionally; which is principally all the culture they require.

But these trees may also be employed as timber-trees, on the evergreen forest-tree plantations. See FOREST TREES.

They are cultivated in all the public nursery grounds for sale, and may be transplanted in autumn, or almost any time in open weather, from October until March or April.

Method of Propagation, &c.

The method of propagating both these trees, is by seed, layers, and cuttings.

By Seed.—Both the sorts ripen seed in England, and are also obtained in great plenty from abroad by the seedsmen; and which should generally be sowed soon after they are ripe, or as soon as they can be obtained in autumn or spring; sowing them in pots or boxes of light earth, covering the seeds half an inch deep, and place the pots, &c. in a sheltered warm situation, or under shelter of a frame in bad weather; especially if sowed in autumn; that the seeds may be protected from severe frost, and continued forward in their vegetative efforts: and thus they will sometimes come up in the spring; which, however, are frequently apt to remain in the ground till the second year; observing when the plants are come up, the pots should be placed in an east border, to have only the morning sun, but open to the free air, giving frequent but very moderate waterings all summer; and in winter remove the pots again to a sheltered place till spring; then may be pricked out in nursery-rows, or if they are very small and weakly, let them remain in the pots another year, placing them in the shade during the summer, and in a sheltered place in winter; and in spring fol-

T I L

lowing plant them out in the nursery, in rows a foot or two asunder, to remain to acquire due size and strength, for final transplantation.

By Layers.—The young shoots only of one or two years growth are the proper parts for laying, which may be performed early in autumn, bending down the branches to the earth; and lay all the young wood on each, either by slit, or twist-laying, with their tops only appearing a little above ground; shortening any that have much longer tops than the others, (see LAYING): thus they will most of them emit roots in the earth, and be proper plants by autumn following; when, or rather in spring after, they should be separated from the stools, and planted in nursery-rows, to remain two or three years, or till of due size for the shrubbery, &c.

By Cuttings.—Autumn is the best season for planting the cuttings, which must be of the young shoots, principally all of the same years growth; and should be planted in a shady border. Taking therefore opportunity of showery weather, if possible, and chusing the most robust young shoots, cut them off with a small part of the old wood, where practicable, and plant them in rows a foot asunder, closing the earth well about them: they will be properly rooted in one year, fit for planting out in wider nursery-rows.

TILIA.

Lime, or Linden-tree.

Consist of only two species, both of them very eminent hardy deciduous trees, of formal growth, proper for ornamental and timber plantations, &c. they rising with large upright trunks a considerable height, branching numerously all around, into large regular conical heads, adorned with broad heart-shaped leaves, and small pentapetalous flowers, in loose bunches.

Class and order, *Polyandria Monogynia*.

Characters.] CALIX is concave, five-parted, coloured, and deciduous. — COROLLA, five oblong, obtuse petals, crenated at top. — STAMINA, numerous awl-shaped filaments, and simple antheræ. — PISTILLUM, a roundish germen, slender style, as long as the stamina, and a pentagonal obtuse stigma. — PERICARPIUM, a globular, coriaceous, quinquevalvular, quinquelocular capsule, opening at the base, containing roundish seeds singly in each loculi or cell; though very com-

commonly there is but one seed in the whole, and so situated that the capsule often appears unilocular, if incautiously examined.

There being but two species, one is a European tree, and the other is of America; each comprehending some varieties, and are all very hardy, and of the deciduous tribe.

¹ *TILIA Europea.*

European or Common Lime Tree.] Rises with an upright straight trunk to a great height and magnitude, branching regularly all round into a large conical head; garnished with large, broad, heart-shaped, acute-pointed, serrated leaves, of a light-green colour; and small whitish-green flowers in bunches, at the ends of the branches, having all the flowers destitute of nectaria.

Varieties.] Common green-twigged Lime-tree, having all the young shoots of a light-green colour—Red-twigged Lime-tree, having all the shoots of a beautiful red colour, appearing very singular in winter, when destitute of leaves.—Large-leaved—Smaller-leaved—Rough or elm-leaved—Variegated-leaved, &c.

The green and red-twigged varieties are tolerably permanent, so that being raised from seed, the plants of each will be mostly similar to the parent tree.

This species grows naturally in England and most parts of Europe, and has been long cultivated as an ornamental tree in garden plantations, both to grow rural, and to form hedge-work regularly trained.

² *TILIA Americana.*

American Black Lime Tree.] Grows with an upright large lofty trunk, branching regularly into a large formal head, having the branches covered with a blackish-brown bark; large, broad, heart-shaped, acuminate, serrated leaves, of a deep-green above, and paler underneath; and small greenish flowers in bunches at the ends of the branches, having all the flowers furnished with nectaria.

Varieties.] Larger-leaved—Smaller-leaved.—Carolinian long-pointed-leaved.

Both the species, and their respective varieties, flower in summer; the flowers small, and of inconsiderable appearance, and are succeeded by plenty of ripe seed in autumn, contained in small coriaceous or leathery capsules; and by the seed all the sorts are easily raised in beds of common earth.

These noble trees are quick handsome growers, and obtain a great stature and substance of trunk, particularly the Common Lime, which grows sixty or seventy feet high; and there are accounts of some that have measured ninety feet in height, and more than eight or ten yards circuit in the trunk, with branchy heads proportionably large; but the timber being of a soft light texture is unfit for any strong purposes; is however excellent for numerous light uses, in the turnery and carving branches particularly.

But for purposes in gardening, the Lime-tree has been long in great esteem for ornamental purposes, in various garden districts, being valued for its quick and fine picturesque growth and large elegant light-green foliage, that effect a very distinguishable diversity; was therefore in great repute formerly to plant for avenues, and arrange on the boundaries of extensive lawns, and other spacious open spaces, as well as to disperse in parks, &c. both as detached single objects, and in groups, also to plant for shade; and in all of which suffered to grow rural, and display their beautiful conic heads: they were likewise used for forming ornamental hedge-rows in large gardens, and along near the fronts of houses by road sides, &c. and trained regular by clipping them annually once or twice in summer; and were also often trained in regular cones, pyramids, hemispheres, arches, &c. though for the general part they are considerably better calculated for rural objects, than for any kind of hedge-work, or other regular training, especially as they generally begin to drop their leaves the earliest in autumn of any other tree: I should therefore advise all the sorts of Limes to be employed principally only as rural trees, and disposed at sufficient distances to allow them full scope to branch out all around, and exhibit their heads distinctly; and in which they will always appear considerably the most conspicuously ornamental.

Though from the circumstance of these trees shedding their leaves early in autumn, which is more peculiar to the large than smaller leaved kinds, they are not in such general repute to plant for ornament in gardens as formerly, because in very dry hot summers the leaves often begin falling in July or August,

gust, and cause a continual litter for a long time.

However, for the singularity of their handsome growth, and foliage, they highly demand culture both for variety, ornament, and shade; and if principally the red-twigged sort is planted, they will have an agreeable effect, even in winter, when entirely devoid of leaves.

These trees are likewise proper to plant as forest-trees, as they will soon arrive to timber; and the wood being soft and tough, is valued for making many sorts of household utensils, and for various light purposes in carved and turnery works, as before noticed.

For all of which purposes, these trees may be planted almost any where, as they will prosper in any common soil and exposure; are raised in abundance, in all the nurseries, for sale, and may be transplanted any time in open weather, from October till March.

Method of Propagation, &c.

The propagation of these trees is by seed, by layers, and by cuttings.

By Seed.—This ripens abundantly in October, which may be beaten down with a long pole, keeping the green-twigged and red-twigged sorts separate; and may either be sowed soon after, or preserved in sand till spring; sowing them in a bed or border of common earth, previously digging the ground, and divide it into four-feet wide beds; then draw the earth off the surface evenly, about an inch deep, into the alleys; and then sow the seeds thinly, and touch them lightly down into the earth with the back of the spade; which done, directly earth them over, the depth just mentioned, which finishes the work of sowing.

Being thus sowed, they will all come up freely in the spring; at which time be careful to keep the beds clean from weeds, and give some moderate waterings in dry weather, to forward the plants in growth as much as possible, fit for planting out in nursery-rows by autumn following; though if they have shot rather weakly, let them stand another year: then planted out in rows two feet and a half asunder, by eighteen inches distance in the lines; here to remain three or four years or more to acquire due size to transplant for the purposes intended,

trimming off large side-branches from the lower part of the stem occasionally, to encourage their aspiring more expeditiously at top, which must be always suffered to remain entire.

These trees, when raised from seed, generally in the end assume a more handsome and expeditious growth, than such as are raised from layers and cuttings.

When they are from about five or six to eight or ten feet high, they are of proper size for final transplantation: though if any are designed principally as forest-trees for timber, it is adviseable to transplant them finally in their destined places, while they are young, and not more than from two or three to five or six feet high.

By Layers.—All the sorts grow freely by this method: and is also, or by Cuttings, a very certain method to continue the varieties.—For the purpose of furnishing layers, proper stools must be prepared (see *STOOLS*), and the young shoots of a year or two old, are the proper parts to lay; which should be performed in autumn or winter, by slit-laying, shortening the tops of each layer within a little of the ground: they will all be well rooted by autumn following, and mostly fit to plant out in the nursery in rows, and there managed as the seedling Limes just above directed.

By Cuttings.—Cuttings of all the sorts of Limes will grow, though not near so readily as layers: however, when cuttings are intended, chuse the strong young shoots of the year, in autumn or spring, and plant them in a moist good soil; or any scarce sorts may be planted several together in pots, and plunged in a hot-bed; they will more readily strike root.

TOLUIFERA.

Balsam of Tolu Tree.

It is a large tree of South America, retained here in stoves by the curious for variety; is adorned with large winged leaves, and bunches of pentapetalous flowers.

Class and order, *Decandria Monogynia*.

Characters.] CALIX is monophyllous, bell-shaped, and quinque-dentate at top.—COROLLA, five petals, four of them being linear and equal, but the fifth is twice as large as the others, and nearly heart-shaped.—STAMINA, ten very short filaments, having antheræ longer than the calix.—PISTILLUM, an

an oblong germen, very short style, crowned with an acute stigma.—PERICARPIUM and SEMEN, at present undescribed.

There is but one species, viz.

TOLUIFERA Balsamum.

Balsam of Tolu Tree.] Rises with a strong robust trunk, branching numerously and spreading, thirty or forty feet high, covered with a thick tough brown bark, large pinnated leaves, composed of several pair of oblong oval lobes, terminated by an odd one; and at the axillas small bunches of yellow flowers, having smaller petals, and one large.

It grows naturally in the Spanish West Indies, and in this country must be cultivated in pots, and placed always in the stove, and managed as other tree and shrub exotics of that department.

A balsam of great virtue is extracted from this tree, and is much used in medical compositions.

This tree is raised from seeds obtained from abroad by the seedsmen; which should be sowed as soon as they arrive in pots of light earth, and plunged in the bark-bed; and when the plants are come three or four inches high, pot them off separately, giving water, and plunge them again in the bark-bed; and afterwards managed as directed for other woody exotics of the stove. See STOVE PLANTS.

TOMENTOSE Plants.

Such as are covered with *Tomentum*, being a sort of woolly or hoary, downy pubescence, which covers the surface of many plants, more particularly those that inhabit the neighbourhood of the sea; and many of which plants having their leaves and branches so closely covered with this substance as to give them a hoary white appearance.

TOURNEFORTIA.

Tournefortia.

Consists of several shrubby exotics from the hot parts of America, and cultivated here in stoves for variety; one of which is a climber, the others erect growers, garnished mostly with oval and lanceolate simple leaves, and monopetalous infundibuliforme flowers at the sides and ends of the branches.

Class and order, *Pentandria Monogynia.*

Characters.] CALIX is monophyllous, five-parted, and permanent. — COROLLA is monophyllous, funnel-shaped, with a cylindric tube, globular at the base, and with a spread-

ing brim, cut into five acuminate horizontal segments. — STAMINA, five awl-shaped filaments in the mouth of the corolla, having acuminate connivent antheræ. — PISTILLUM, a globular germen, simple style, and single stigma. — PERICARPIUM, a globose berry, having four roundish seeds.

This genus received the name *Tournefortia* in honour of M. Tournefort, the illustrious French Botanist.

There are about eight species in this genus, mostly of a shrubby nature, and perennial in root and top; and the most noted sorts in the English gardens are the following; all of which being natives of the hot parts of America, require to be continued always in a hot-house in this country.

¹ *TOURNEFORTIA Volubilis.*

Volubilate or Twining Tournefortia.] Rises with long, slender, woody volubilate stalks, twining round any adjacent support, fifteen or twenty feet high; oval, acuminate, smooth leaves, on reflexed footstalks; and small white flowers in loose spikes, at the sides and ends of the branches.

² *TOURNEFORTIA Suffruticosa.*

Suffruticose or Undershrubby Tournefortia.] Rises with a shrubby stalk, branching moderately about three or four feet high; oblong, almost spear-shaped, hoary, whitish leaves; and small white flowers in bunches, at the sides and ends of the branches.

³ *TOURNEFORTIA Serrata.*

Serrated or Tree Tournefortia.] Rises with a shrubby, upright, thick stem, branching twelve or fourteen feet high, or more; having oval, serrated leaves on rough spinous footstalks; and white flowers in recurved spikes terminating the branches.

⁴ *TOURNEFORTIA fœtidissima.*

Fœtid Tournefortia.] Rises with woody stalks and branches, eight or ten feet high, or more, having oval, spear-shaped, hairy leaves; and white flowers terminating the branches in ramose, pendulous spikes.

⁵ *TOURNEFORTIA Cymosa.*

Cymose Tournefortia.] Rises with woody, branching stalks, six or eight feet high; large, oval, oblongish, naked, smooth, entire leaves; and white flowers terminating the branches in cymose spikes.

⁶ *TOURNEFORTIA humilis.*

Dwarf Tournefortia.] Rises with shrubby, low, slender stalks, branching moderately two or three feet high, spear-shaped, close-

sitting leaves, and white flowers in simple or unbranched recurved spikes, produced laterally, or along the sides of the branches.

These plants remain in leaf, mostly the year round, and flower in spring or summer, &c. succeeded by small succulent berries, containing three or four seeds.

They being all very tender exotics, that require the continual shelter and heat of a stove, in this country must be cultivated in pots of good earth, and placed in the stove accordingly, and treated like other shrubby exotics of this collection, as directed under the article STOVE PLANTS.

All the sorts may be raised from seeds obtained from abroad, where the plants grow naturally; and it is adviseable to sow them as soon after their arrival as possible, in pots of light mould, and plunged in a bark-bed; giving occasional sprinklings of water, and they will probably come up the first year; or if they should remain longer in the ground, continue to keep the mould in the pots all the while moderately moist; and when the plants are come up, and advanced three or four inches high, prick them out singly in small pots, and plunge them in the bark-bed, and continue them constantly in the stove.

Their propagation may also be tried by layers, &c. in pots plunged in the bark-bed.

TRACHELIUM.

Throatwort.

One hardy herbaceous perennial, of the flowery tribe, for the pleasure-ground, compose this genus; rising half a yard high, with oval leaves, and umbelliferous-like blue flowers at top.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX is small, five-parted, and placed above the germen.—COROLLA, one funnel-shaped petal, with a long, slender, cylindric tube; and divided at the brim into five small concave spreading segments.—STAMINA, five capillary filaments, the length of the corolla, having single antheræ.—PISTILLUM, a triquetrous, subrotundous germen, slender style, and globose stigma.—PERICARPIUM, a roundish, obtuse, trilobate, trivalvous capsule, of one cell, having numerous small seeds.

There is but one species, viz.

TRACHELIUM *Cæruleum*.

Blue Trachelium or Throatwort.] Hath a thick, fleshy, fibrated, perennial root; up-

right stalks, about half a yard high; garnished with oval, spear-shaped, serrated leaves, and terminated by many small fine blue flowers, in a sort of umbellate clusters in June and July, ripening seeds in September.

It is a native of shady places in Italy and the East, and is cultivated in our gardens to encrease the variety; planted in light dry soils, where it will abide several years: also, if sowed in the crevices of old walls, ruins, and rock-work, they will flourish, and be of great duration; but when cultivated in rich moist soils, they are not so durable, often proving biennial.

It is propagated by seeds sowed in autumn, soon after they are ripe, or early in spring, in a bed or border of light earth; the autumn sowing will probably come up more freely than that of the spring. Observing when the plants are two or three inches, prick them in nursery-rows six inches asunder, to remain till autumn; then may be transplanted where they are to remain.

TRADESCANTIA.

Virginia Spiderwort, or Flower of a Day.

It is a hardy herbaceous perennial, of the flowery collection, for adorning the pleasure-ground; rising with erect annual stalks, a moderate height, ornamented with very long narrow leaves, and tripetalous flowers.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, three oval, concave, spreading, permanent leaves.—COROLLA, three large, orbicular, plane, spreading petals.—STAMINA, six slender, erect, hairy filaments, having kidney-shaped antheræ.—PISTILLUM, an oval, obtusely-trigonal germen, filiformous style, crowned with a trigonal obtuse stigma.—PERICARPIUM, an oval, trivalvous, trilocular capsule, covered with the calix, having numerous small seeds.

There are three species, but not more than one in the English gardens, viz. *Common Virginia Spiderwort*; comprehending several varieties, all hardy perennials.

TRADESCANTIA *Virginiana*.

Virginian Tradescantia, commonly called Virginia Spiderwort, or Flower of a Day.] Hath a thick root, furnished with many fleshy fibres, crowned with many narrow leaves near two feet long; amidst them erect, thick, smooth stalks, two or three feet high; garnished, long, graminous leaves singly; and large tripetalous,

pus, blue, and other coloured flowers in the varieties, crowning the stalks in close clusters.

Varieties are] Common pale blue-flowered. Deep blue flowered—Purple-flowered—Red-flowered—White-flowered.

They all flower in June; each flower is generally but of one day's duration; hence the name *Flower of a Day*, but the same plant continues producing a plentiful succession of new flowers every morning, for a month or six weeks, succeeded by plenty of ripe seed in autumn.

This species, &c. is a native of Virginia, but have been many years in the European gardens as ornamental flowery plants, for the common borders; they may therefore be planted in any of the borders, or other compartments of the pleasure-ground, on which they will abide by the roots many years, producing new stalks annually in spring, and flower very ornamentally every summer; and will multiply exceedingly both by their roots, and scattered or self-sowed seeds; even so much as often to over-run the ground, and require trimming in to reduce them within proper bounds.

They are all easily propagated by parting the roots in autumn, or early in spring; also by seed sowed in the spring, in any bed or border of common earth, and raked in; and the plants will rise plentifully, and be fit to prick out in summer, to gain strength till autumn, then transplanted finally.

TRAGOPOGON.

Goat's Beard.

Consists of hardy, herbaceous plants, mostly biennials, the principal of which in the gardens is an esculent called *Salsify*, esteemed for its carrot-shaped, eatable root, and by some for the tender shoots of its young stalks in the spring, to eat like *asparagus*; are mostly tap-rooted plants, with the roots crowned with long narrow leaves, and with upright stalks in spring, of moderate height, surmounted by large compound flowers.

Class and order, *Syngenesia Polygamia Æqualis*.

Characters.] CALIX, a compound flower having the general cup single, composed of eight spear-shaped leaves, alternately larger and joined at the base.—COROLLA, the general flower is compound, imbricated, and uniform, composed of many monopetalous

tongue-shaped hermaphrodite florets, five-parted at top.—STAMINA five very short filaments, having cylindric antheræ.—PISTILLUM, an oblong germen filiforme style, crowned with two revolute stigmas.—PERICARPIMUM, none, the seeds, one in each floret are angular, rough, crowned with down, and lodge in the swollen connivent calix.

From the circumstance of the seed being covered with a pappus or down as they remain in the cell, resembling a goat's beard, it obtained the name of *Tragopogon*, or Goat's Beard.

There are ten or twelve species, but many of which being plants of no estimation for use, are but little known; and the most noted sorts are, first the *salsify*, an esculent, having an eatable root and stalks, &c. and two others sorts principally for variety: the first two sorts are biennials and the third a perennial.

¹ TRAGOPOGON *Porrifolium* (Biennial)

Leek-leaved Tragopogon, commonly called Salsify.] Hath a perpendicular, carrot-shaped, white, eatable root, a foot or more long, crowned with many long leek-shaped entire leaves, closely gathered; and when it runs to seed, rises with upright, hollow, smooth, whitish stalks two feet high, terminated with large compound blue flowers, having the peduncles thickest above, and the calix longer than the radius.

It flowers in July, and the seeds ripen in autumn, then wholly decays.

This plant grows naturally in meadows in some parts of England, &c. but is cultivated in gardens in the manner of carrots, for its long carrot-shaped root, which attains a moderately large size by autumn and winter, when it is boiled for use, and served to table in different ways, and is very tender and palatable: also the young shoots of the flower-stalk in spring and summer, cut while young and tender, when only a few inches high, are dressed in the manner of asparagus, and served up to table with butter, &c.

It being a biennial, rises from seed in the spring, and attains perfection in the root in autumn following, remaining good all winter, and in spring after shoots up stalks for flower and seed, and the root then becomes sticky and useless, and totally perishes soon after the seeds are ripe.

² TRAGOPOGON *Pratense* (Biennial.)

Meadow Tragopogon, or Greater Yellow Goat's Beard.] Hath a taper fibrated root, crowned with very long, narrow, acute, entire leaves gathered together; upright stalks near a yard high, garnished with long narrow leaves singly at each joint; and terminated each stalk with one large compound yellow flower, having the calix and radius of equal length.

Variety.] Smaller Meadow Tragopogon, having much narrower leaves, and stalks only a foot high.

Both the varieties flower in June and July, and the seeds ripen in September.

They grow naturally in meadows in England and most part of Europe; and are sometimes cultivated in gardens for variety, and the young shoots in spring are often gathered and dressed, as observed of the Salsafy, being frequently brought to the London markets by the simplers who gather them in the meadows in April and May; or may be raised in gardens by sowing their seed in spring in rows six or eight inches asunder, and the plants will shoot up for use in the spring following.

³ TRAGOPOGON *Dalechampii* (Perennial.)

Dalechamp's Greater Hawkweed, or French Tragopogon.] Hath the root crowned with many large, oblong, runcinated, deeply indented leaves; low stalks only about five or six inches high, surmounted by one large yellow flower, having a monophyllous calix shorter than the corolla, appearing in June or July, and the seeds ripen in autumn.

All these plants are hardy: the first two being biennials, rising one year from seed and the next shoot up into stalk, producing flowers and seed, then wholly decay; and the third is a perennial, durable in root, sending up stalks annually in spring, which decay in autumn.

The first species (*Tragopogon Porrifolium*) is the principal sort for general culture, as an esculent, and as such merits culture in every kitchen-garden principally for its roots, as before observed, chiefly for autumn and winter use; they being easily raised from seed in the open quarters, and will arrive to perfection only in autumn, and continue good till they begin to shoot in spring following.

It is much cultivated in the London kitchen-gardens for market, where it is commonly brought in bunches, in autumn and winter.

The other two species are retained in some gardens for variety, and the second sort particularly, is also sometimes cultivated for its tender shoots in spring, as already hinted.

Method of Propagation, &c.

The *Salsafy* is raised only from seed sowed in spring, in March and April, in an open situation to remain, sowing it either broadcast and raked in, or in shallow drills, eight or nine inches asunder, scattering the seeds thinly, and cover them half an each deep; and when the plants are come up two or three inches high, thin and weed them by hand or hoe, leaving them eight or ten inches asunder, repeating the weeding as may be required during the summer, which is all the culture they require; and they will have large roots by September or October. When you may begin taking them up for use; and in November, when the leaves begin to decay, a quantity, may be taken up and preserved in sand for use in time of severe frost, when those in the ground cannot be dug up.

In spring, when those remaining in the ground begin to shoot, the shoots, when a few inches high, may be cut for use as before mentioned; which, when quite young and tender, are excellent eating. Suffer, however, always a few plants to run up to stalk every spring, to produce seed for sowing.

The other two sorts may be raised also from seed like the *Salsafy*, and the plants, when a little advanced in growth, may be planted out if they are required for variety in any particular part. If the *Tragopogon Pratense* is required for its shoots, it should remain where sowed, and thinned to proper distances.

But the third sort may also be propagated by parting the roots in autumn or spring.

TRAINED TREES.

For walls and espaliers.

The appellation of Trained Trees, is to be understood principally of young fruit-trees designed for walls and espaliers, being trained in the nursery to the intended form, by planting them against any kind of walls, pales, reed-hedge, or other close fence, when a year old from the grafting or budding, training

ing them in the manner of wall or espalier trees, for two, three, or more years, till they obtain a good spread of branches, arrived to a fruitful state, in order that any persons, being in haste to have their walls or espalier covered at once with bearing trees, it may be effected in one season; as the trees thus trained in the nursery, &c. being transplanted in autumn or spring to the places intended, they will both cover the wall or espalier considerably at once, and bear a great deal of fruit the ensuing summer, if a favourable fruit season.

So that whosoever may incline to have his walls thus at once furnished with bearing trees, without waiting three or four years longer for younger trees attaining a bearing state, may be supplied with such at all the public nurseries, where large quantities are always ready trained for sale, more particularly peaches, nectarines, and apricots for walls; likewise in many places, cherries and plums, &c. also apples, pears, and other fruit-trees for espaliers; and are very eligible both to furnish the walls of any new garden, or newly erected walls in old ones, either wholly or in part, to bear some fruit till younger trees, planted untrained, come forward and become fruitful, or may be used occasionally to supply the place of very old trees that may happen to fail or bear bad fruit; in all of which, the planting of Trained fruitful trees may prove so far preferable to quite young untrained and unfruitful ones planted at the same time, in that there will be three or four years difference in the time of their bearing, which is very a material object of consideration; and that, if the Trained Trees are purchased in the public nursery gardens, you are freed from the trouble of first training them to the requisite form, which requires particular attention the two first years, the effecting of which, often ruins many young wall and espalier trees at first setting off, when under the hands of ignorant practitioners; and as to the expence of the purchase, between Trained bearing Trees of five or six shillings, and that of one or two years old untrained ones, of a shilling or eighteen pence, cannot be any great object to persons of fortune, or of any tolerable circumstances in life, at least to furnish some part of the best walls, or to plant alternately with young untrained trees.

Therefore in both public and private nurseries, it is of much importance to have some of the best sorts of wall and espalier trees always in training for walls, &c. against any kind of fence, either walling, paling, or reed-hedges, both dwarf and half-standard wall trees; also against ranges of stakes in the open quarters for espaliers, that there may always be some well trained spreading trees arrived to a fruitful state, to furnish any place as above occasionally with immediate bearing trees of some considerable spreading growth.

When, therefore, it is intended to raise trained fruit-trees for walls and espaliers, a quantity of the best young plants of the respective sorts, both dwarf and half standards aforesaid, of one year old, with the first shoots from the budding and grafting entire should be transplanted in autumn against any kind of fence of any aspect in a free situation, not less than four or five feet high; either a wall, paling, reed-fence, &c. before hinted, placing them eight or ten feet distance, and here to remain for training as below.

The trees being thus planted, then in spring following, just as they begin to make an effort for shooting, they should be headed down, that is the first shoots from the budding, &c. to be cut down to within three or four eyes or buds of its origin, or place of insertion in the stock, especially those intended for dwarfs, also the half-standards, if worked on tall stocks; and this heading down both prevents their running up too high with a single naked stem, branchless below, and causes them to throw out lateral shoots from the lower part to fill the wall or espalier regularly with branches quite from the bottom upward; for being thus cut over low, they will soon after push forth strong shoots from all the remaining lower buds, sufficient to give the tree its first proper formation as a wall tree, &c. which shoots when of due length in summer, should be trained along to the fence equally to the right and left, in a somewhat inclined position at full length till next spring, when these shoots may also be cut down to six or eight inches length, to force out a further supply of more branches near the bottom, for there is nothing like being well furnished with

with branches below at first setting off, to form a good foundation, whereby you will be able to keep every part of the wall from the very bottom to top covered with bearing wood, for no part of a good wall should be lost.

So that agreeable to these hints, continue shortening more or less the two or three first springs on the last summers shoots, as you shall see necessary, in order to obtain a proper spread of lower branches to give the tree its intended form; though this work of pruning short to obtain laterals may also be performed occasionally in summer, in May or early in June on the strong young shoots of the year, cutting or pinching them down to a few eyes, and they will thereby throw out lower laterals the same season, and by that means a year's growth is gained.

According as the supply of branches thus gained by the above methods arrive to proper length in summer for training in, they should be accordingly all trained along close to the wall, and if any fore-right or back shoots come out, rub them all off close; leaving, however, all the well-placed side shoots in every part, and let the whole, or as many as possible, be trained in during this season, to have a plenty to chuse from in the general pruning season of winter or spring, training them close to the wall, &c. equally to the right and left, as aforesaid, on each side of the tree, in a spreading somewhat horizontal manner, no where crossing one another but at parallel distances, and mostly all at full length during the summer's growth; thus to remain till the general winter or spring pruning.

In the winter pruning we are to observe, that if more wood was trained up in summer than now appears necessary, or that can be trained in with due regularity, should retrench such superfluities; likewise any remaining fore-right or back shoots and other irregular growths omitted in summer, not eligibly situated for training in, should also be now all pruned out, cutting every thing of the above nature, both superabundancies and irregularities, quite close to their origin; being careful, however, to leave all the regular, well-placed, useful shoots that can readily trained with due regularity, without crowding or crossing one another, all of which should also be cleared from all lateral or side

shoots, if any; and with respect to their being shortened more or less, or left entire, you will order according to your discretion, agreeable to the afore-mentioned hints, and also as noticed below, as the different sorts may require; though if any rambler extend considerably beyond all the others, it must be reduced, or cut down to some lower shoot, consistent with the general form and extent of the rest of the branches; then, after performing these regulations, proceed to the training and nailing in the whole close to wall, &c. in exact order, by ranging them equally each way, in a spreading fanned manner, all as straight as possible, somewhat horizontally, no where crossing the branches, but all ranged parallel as aforesaid, one above another, four, five, or six inches distance, according to the sorts, making the opposite branches of each side range as equally as possible in the same position.

Thus, after having obtained a regular spread of branches, proceeding immediately near the head of the stem, sufficient to effect the proper expansion requisite to form a trained wall or espalier tree, they must then be pruned according to the method peculiar to each respective sort of fruit, as directed in their culture, each under its proper genus.—Some requiring the branches shortened annually, others to be trained mostly always at full length.

For in the general course of training and pruning wall trees and espaliers, it must be observed, that some sort of wall trees require almost a general shortening every year of the annual supply of branches, such as peaches, nectarines, and apricots, which always bear their fruit principally on the young year old wood, have that of each year shortened in the winter pruning, to force out a sufficient supply of succession shoots in proper places all over the tree for the future year's bearing: on the other hand, as apples, pears, plums, and cherries do not want an annual renewal of bearing wood, the same branches continue bearing from two or three to many years old; so that, after undergoing the operation of shortening the first two years wood, to obtain a spread of lower branches to effect the intended form as a wall or espalier tree, they are not afterwards, in the general course of pruning, to be shortened, but generally always trained at full length, except occasionally

tionally shortening some particular young shoot to fill a vacancy. See each kind under its respective head, also the article of *PRUNING Dwarf Trees, Espaliers, &c.*

The training of espalier trees is effected exactly in the manner as above, only these may be also trained as they stand in the nursery lines, in the open quarters or borders, &c. by ranging some stout stakes in the ground along one side of each tree, not in a continued straight range immediately the way of the row, but those of each tree ranged separate and obliquely, somewhat cross ways the row as it were, that the branches of the different trees may range beside one another, and thereby have more room to extend the branches both ways, than the common distance in the nursery-lines would admit, if ranged directly the way of the row.

Observe that as it may sometimes happen some of the trained trees, both of the wall and espalier kinds, in the course of training, may assume a state of vigorous luxuriant growth, either in general, or in some particular parts, producing strong, rampant, rude shoots of a very unfruitful-like nature; they in such cases, should be ordered accordingly in a peculiar manner, till they have exhausted their redundancy of sap, or excessive luxuriance, and effect a more moderate state of growth.

That, therefore, where a general luxuriance prevails, while under the course of training or after, it is adviseable in the work of pruning to use the knife with moderation, in regard to thinning and shortening, and rather humour the trees somewhat, according to their natural tendency, by leaving the shoots and branches thicker or closer together than the common rule, and to such as are usually shortened, as in peaches, nectarines, &c. they should be shortened much less in proportion; that by dividing the sap amongst a greater number, as well as larger extent of branches, it checks the luxuriance which would take place in a smaller number and less extent of growth. For the more wood we cut out of a generally vigorous shooting tree, and the more the shoots are shortened, as often erroneously practised, the more vigorous will it continue to shoot without ever becoming properly fruitful; and if severe cutting is repeatedly continued, the tree often exhausts

itself so greatly by luxuriant shooting, that it suddenly assumes a weak consumptive state.

But that the natural inclination of very vigorous young trees, being somewhat indulged at first by training as many branches as can be conveniently laid in, and those that require shortening, cut but moderately, or some very luxuriant ones hardly at all; which being practised two or three years with discretion, it will gradually reduce the trees to a moderate growth, and good state of bearing; when they may be ordered in the common way peculiar to the different sorts.

On the other hand, such trees as are vigorous only in particular shoots, may, in some cases, have such shoots radically retrenched, and in others reserved; that if a very vigorous shoot runs considerably stronger than all the rest, and seems to support its vigour at the expence of the others in its neighbourhood, it should be retrenched to the very origin, as early in the summer as discoverable; in other cases, if a luxuriant shoot arise in any vacant space, towards the bottom especially, where a supply of more wood is wanted, it may be retained, and pinched or topped down to a few eyes in May or June, it will send out several laterals below, the same season, and instead of one rude luxurious shoot, there will be four or five of moderate growth to fill the vacancy, more effectually, and that will much sooner attain to fruitfulness.

Thus far is chiefly all we have to observe relative to the ordering of Trained wall and espalier Trees in the nursery, which being in training from three to four or five years, they obtain a handsome spread of fruitful branches, fanned in the requisite regular form for the purposes intended; so as when planted in the garden, they at once cover a large space of walling, &c. bearing good fruit the following summer.

Other particulars respecting their culture, after being planted in their destined places in the garden, are exhibited under the heads separately of the respective sorts. See also *DWARF TREES, ESPALIERS, and PRUNING.*

Notwithstanding what we have here advanced respecting the planting of Trained Trees for walls, &c. we would also observe, that

that for any general plantation, unless good Trained Trees can be readily obtained, from three or four to five or six years old, of a clear free growth, it will be better to plant entire young trees of one or two years old, immediately from the nursery rows untrained, planting them at once where they are to remain, and they will probably root more effectually, and assume a freer growth than stunted Trained Trees, managing them as directed for the Trained Trees, to give them the due formation, and afterwards, agreeable to the rules of pruning directed for the different sorts in their proper places.

But some, to have as great a chance as possible, plant both young untrained trees to remain, and Trained Trees of a bearing state, dwarfs and half-standards between, so as to cover the wall more effectually at once, and furnish a supply of fruit directly, as it were, and until the young ones are trained and arrive to bearing; then as they advance in growth, and if they appear the most thriving, the Trained Trees are gradually cut away, leaving the younger, or more thriving trees, to occupy the wall wholly at last.

In most of the public nurseries, they raise many Trained Trees for sale, which occupy all their close fences of walls, pales, or reed-hedges, planted near together, and after being in training two, three, four, or more years, till of a good spread and become fruitful they are ready for sale, and fetch a very good price, generally from three to five or ten shillings per tree, according to the sorts, age, and goodness of growth; which pays well for the trouble of training, as any sort of fence of any aspect, openly exposed, serves for training them to the proper form.

TREILLAGE,

Or TRELLIS.

A *Treillage* is ranges of stakes and railing on which to train espalier trees; also occasionally for wall trees, where the wall does not admit of nailing the branches immediately against it; likewise for training wall trees in forcing frames, &c. and may be of different degrees of taste for use and ornament, as well as of different dimensions, from four or five to six or seven feet high, as noticed below.

For common espalier fruit trees in the open ground, a *Treillage* is absolutely necessary, and may either be formed of com-

mon stakes or poles, or of regular joinery work.

The cheapest, the easiest, and soonest made *Treillage* for common espalier trees, is, that formed with any kind of straight poles or stakes of underwood, as cut in the coppices or woods, being cut into proper lengths, of from five to six or seven feet, may expeditiously form a good *Treillage*, by driving them in the ground in a range a foot distance, all of an equal height, and then railed along the top with the same kind of poles or rods, to preserve the whole straight and firm in a regular position. See *ESPALIER*.

Therefore, to form a *Treillage* of this kind, we must provide some bundles of straight poles or rods, either of ash, chesnut, or of any other firm durable wood; which, if in the country, may be readily obtained in the adjacent woods or coppices, at a moderate expence, and are sold at many of the timber yards in the vicinity of great towns; chusing such as are perfectly straight and of sufficient substance, i. e. full an inch and half thick, cutting them into six or seven feet lengths, as before noticed, and having pointed them at one end, drive them with a mallet into the ground in a straight range close along the row of trees, a foot deep at least, and the same distance in the line; after which saw them even at top, all of an equal level from four to five or six feet high, then let slips of deal or straight poles, be ranged horizontally along the top the whole length, and nailed down to each stake, which finishes the whole firmly in a straight range, as well as give an air of greater uniformity; and when thus finished, the branches of the espalier trees are to be trained and extended along horizontally from stake to stake, as directed for the different sorts under their proper heads, and in the article *ESPALIER*.

To render the above sort of *Treillage* still stronger, may run two, three, or more ranges of rods, along the back part of the uprights, a foot or eighteen inches asunder, fastening them to the upright stakes either with pieces of strong wire twisted two or three times round, or by nailing them.

But where a more elegant and ornamental *Treillage* is required in any particular district, it is formed with regularly squared posts and rails of hard timber, neatly plained and framed

Framed together; having for this purpose deal or oak posts, uniformly worked two or three inches square; but if the main posts are of oak, it will be of particular advantage in respect to strength and durability, fixing the main posts in the ground ten or twelve feet asunder, with smaller ones between, ranging the horizontal railing from post to post in three or more ranges; the first being ranged about a foot or eighteen inches from the bottom, one at top, and a third along the middle space, and if thought convenient may range one between each of the intermediate spaces; then fix thin slips of lath, or the like, upright to the horizontal railing as far as the branches of the trees extend, ten inches or a foot asunder; and paint the whole white in oil colour, to render it more ornamental and durable; and in training the trees, tie their branches both to the railing of the Treillage, and to the upright laths, according as they extend in length on each side.

In either of the above Treillages for an espalier, five or six feet is generally of sufficient height, as if much higher, the winds having greater power, will loosen and displace them.

Treillages for wall trees is in some places necessary, where the walls are built with large stones with the joints irregular and far asunder, not affording opportunities for nailing properly in the due regularity required; in which case a neat Treillage is eligible, erected all along close to the wall, on which to train and tie the branches in regular order.

This kind of Treillage may also be formed with rods or strong laths, erected chequer or lattice fashion, fastened and framed together close to the wall with iron hooks and pieces of wire, as below.

That being provided with a due quantity of clean straight rods or poles, or squared laths an inch thick, and a quantity of hooked iron holdfasts, which are previously driven into the joints of the wall in rows at regular distances, projecting about an inch or inch and half to receive the rods or laths, both horizontally and perpendicularly chequerways nine or ten inches asunder; fixing the first row of holdfasts towards the top, the second near the bottom, and the third along the middle space; this done, and the rods or laths ready, which, if thought proper,

may be squared and planed, then proceed to frame the Treillage by first fixing the rods horizontally in three rows, in the three ranges of hooks, as above; observing, these horizontal rods should be previously chopped off to nothing at each end, so as they may be readily spliced to one another to extend them in length as far as required; thus, having fixed up the three first rows of horizontal poles, fasten up some uprights or standard rods in front of the horizontal ones, five or six feet distance, then range the remainder of the horizontal laths behind the standards, nine or ten inches asunder, fastening them with wire to the uprights, and being all thus placed and fixed, the rest of the standards are fastened up in front at the same distance, and the whole is made fast with wire twisted round the hooks and the crossings or intersection of the rods of the Treillage.

Or a Treillage of the above kind may be formed of squared laths, about an inch thick, planed even and smooth and neatly framed together by mortise and nailing, &c.

When the Treillage in either of these methods is finished, it is advisable to paint the whole all over with white lead, to render it both more beautiful and durable.

In forcing-frames and stoves, where wall trees are intended for forcing, as they are planted both against the back wall, and occasionally against the front glasses, a Treillage is absolutely necessary, for the trees must not be trained close to the wall, &c. therefore, a Treillage should be erected three or four inches from the wall or glasses; formed with squared posts and laths, uniformly framed together in the chequer or lattice manner.

TRIBUS.

Tribes of Plants.

As the whole vegetable creation is distributed systematically into classes, orders, genera, and species, &c. according to the sexual system, there are numbers of plants in these different artificial arrangements, that although they differ essentially in the fructification or sexual method, yet are nearly allied in their general growth, habit, and appearance; and may, therefore, for the greater facility of distinction, agreeable to nature's system, be divided into Tribes according to the affinity they bear to one another

other in their nature of growth, either in general, or particular parts, and their sensible qualities, &c.

For example, they may be divided into Tribes according to the following natural orders.

Herbaceous Tribe.] All plants of the herbaceous or herb kind, rising mostly with leaves immediately from the root, and with soft herbaceous stalks not becoming woody, but mostly die at the end of the same year they were produced.

Ligneous or Woody Tribe.] All trees and shrubs having woody durable stems and branches.

Arboreous Tribe.] All plants of the tree kind rising to a lofty stature. See ARBOR.

Fruticose or Shrubby Tribe.] Plants of the shrub kind, rising but a moderate height, and divide low into several stems, &c. branching in a somewhat bushy manner.

Deciduous Tribe.] All kind of trees, shrubs, and other plants that cast their leaves in winter.

Sempervirent or Evergreen Tribe.] The various trees, shrubs, and other plants that retain their green leaves the year round.

Annual Tribe.] Annual plants, called annuals, being such as are only of one year's duration. See ANNUAL PLANTS.

Biennial Tribe.] Plants of two years duration. See BIENNIAL PLANTS.

Perennial Tribe.] Plants that are perennial or of many years duration, and is applicable both to herbs and trees, though more generally applied to herbaceous perennials. See PERENNIS PLANTA.

Fibrous-rooted Tribe.] All kind of plants with fibrous roots. See RADIX.

Bulbous-rooted Tribe.] Plants with bulbous roots, such as the onion, tulip, lily, &c.

Tuberous-rooted Tribe.] Plants with thick, knobbed, fleshy roots, such as the anemone, potatoe, and Jerusalem artichoke.

Succulent Tribe.] Plants with fleshy, juicy leaves, as in *sedum*, *cactus*, *mesembryanthemum*, *aloe*, *agave*, &c. See SUCCULENTIÆ.

Pinnated Tribe.] All sorts of trees and other plants that have pinnated or winged leaves.

Ensateous or Sword-leaved Tribe.] Plants with sword-shaped leaves, as in *iris*, *gladiolus*, &c.

Spathaceous Tribe.] Plants producing their

flowers out of a spatha or sheath, as in *norcissus*, *galanthus*, and *amaryllis*, &c. See SPATHACEA.

Liliaceous Tribe.] Plants producing flowers with six petals or distinct segments, resembling a lily in form, such as the tulip, &c. See LILIACEÆ.

Papilionaceous Tribe.] Plants that have papilionaceous or butterfly-shaped flowers, such as all the pea and bean kind, and all the other leguminous plants. See PAPILIONACEÆ.

Leguminous Tribe.] Plants having that kind of seed-vessel called a legumen, legum, or pod, as in all the pea, bean, kidney-bean, and other papilionaceous-flowered plants.

Campanaceous Tribe.] Plants with campanulated or bell-shaped flowers, as the *campanula* and *convolvulus*, &c.

Rotaceous Tribe.] Plants with rotated or wheel-shaped flowers, as in *lysimachia*, *anagallis*, &c.

Umbelliferous Tribe.] Plants producing their flowers in an umbel, as in *angelica*, *anethum*, *pastinaca*, &c. See UMBELLA.

Verticillate Tribe.] Plants producing their flowers in a verticillus or whorl, as in *thymus*, *hyssopus*, *melissa*, *origanum*, *scalaria*, *mentha*, &c. See VERTICILLATÆ.

Aggregate Tribe.] Plants producing their flowers in an aggregate, consisting of numerous small flowers or florets, each having its proper calix, and all collected into a close aggregate head, as in *scabiosa*, *statice*, *globularia*, &c. See AGGREGATE.

Compositus or Compound Tribe.] Plants with compound flowers, consisting of numerous florets contained in one common calix, as in sun-flower, marigold, aster, &c. See COMPOSITUS FLOS.

Amentaceous Tribe.] Plants producing their flowers in amentums or catkins, as in *populus*, *corylus*, *fagus*, *betula*, &c. See AMENTACEOUS FLOWERS.

Coniferous Tribe.] All trees and plants bearing that kind of fruit called a cone. See CONIFERÆ and CONUS.

Baccaceous Tribe.] All berry-bearing plants.

Pomaceous Tribe.] Plants bearing fruit of the apple kind (*pomum*) as in the *pyrus malus*, *pyrus communis*, *pyrus cydonia*, *amygdalus*, *prunus*, *mespilus*, *punica*, &c.

Nuciferous Tribe.] All nut-bearing plants.

Oleraceous Tribe.] Esculent or eatable plants for the table, and other domestic uses.

Lurid

Lurid Tribe.] Plants of an ominous appearance, hurtful or noxious; as in *atropa*, *datura*, *nicotiana*, *solanum*, *capsicum*, *digitalis*, &c.

Graminous Tribe.] Grassy plants; all plants of the grass and corn kind.

TRIFOLIUM.

Trefoil, or clover, &c.

The plants are herbaceous annuals, biennials and perennials, rarely cultivated in gardens, but of great estimation for pasture lands as fodder for cattle; have all fibrous roots crowned mostly with tufts of small trifoliate, or three-lobed leaves, and send up stalks in summer a foot or two high, and some trailing; adorned also with trifoliate leaves, and terminated by small papilionaceous flowers in heads or spikes.

Class and order, *Diadelphia Decandria*.

Characters.] CALIX, is monophyllous tubular five-parted at top, and permanent.—COROLLA, is papilionaceous, having the vexillum reflexed and with short wings and carina.—STAMINA, ten diadelphous filaments, having simple antheræ.—PISTILLUM, a nearly oval germen awl-shaped style, crowned by a simple stigma.—PERICARPIUM, a short univalvular pod, containing a few roundish seeds.

There are near fifty different species of *Trifolium*, but many of them being plants, of but little value or estimation, either for garden or field culture, are rarely cultivated; so that the most material sorts are the following two species.

¹ TRIFOLIUM *Pratense*.

Meadow Trefoil or Red Dutch Clover.] Rises with many slender branchy stalks near two feet high; having trifoliate leaves of three large folioles, membranous stipulæ placed opposite round the foot-stalks; and monopetalous reddish-purple flowers in hairy spikes or tufts, at the ends of the branches, in May and June.

Varieties.] Purple-leaved—White flowered, and some others.

² TRIFOLIUM *repens*.

Creeping White Dutch Clover.] Hath trailing, creeping stalks, spreading and rooting at the joints; trifoliate leaves; and white flowers growing in umbellate heads at the sides and ends of the branches, succeeded by pods having four seeds.

Both these species of Trefoil or Clover, are found in abundance in our meadow and pasture grounds, and are the only sorts of this genus for general culture in laying down grass-land, and are raised from seed sowed in May or autumn as directed below.

They are perennials, though the first often proves only biennial, by sometimes dying away after it has ripened seeds, but the second sort is always biennial, growing very close and thick, is more valuable than the other for continued pasture.

However the first sort, or red Dutch Clover, grows abundantly, producing wonderful great crops, and is most excellent for laying down land to cut for fodder for all kinds of cattle for two years; for on account of its biennial nature above-mentioned, it does not always succeed well much longer; though if it is close eaten in summer, or mowed down when coming into flower, it shoots out below from the root again, and often proves somewhat perennial; but considered as a biennial, the farmers commonly sow it with barley in the spring, and when the barley comes off in July or August, the Clover spreads and covers the ground, and shoots up strong early next summer, either to feed off, or mow for hay; and after standing two years, they generally plough the ground again for corn.

But the second sort, creeping white Dutch Clover, is more valuable than the other for laying down ground, designed to be continued long in pasture, its seeds being mixed and sowed with grass; and as it grows low and close, with trailing abiding shoots, spreading every way and rooting at the joints, it soon overspreads the ground, and forms a close thick sward, of many years duration; and affords the most excellent feed for all sorts of cattle.

Both the sorts are propagated by seed, which is sold by all the seedsmen, generally at so much per pound; and from six to eight or ten pounds is the allowance for an acre.

The season for sowing it, is principally in the spring in March and April, or may be sowed in autumn, any time in August, or early part of September; is generally mixed with grass seeds, and sowed broad cast and lightly harrowed in with a short-teethed harrow,

TRI

harrow, and in a day or two after, when the surface is dry, roll the ground with a horse wooden roller, to break the clods and smooth the surface, but the farmers commonly sow these seeds with corn, such as barley, &c. for the sake of making the most of the land, and when the corn comes off the Clover and grass take their growth, though it will prove much more prosperous and forward if sowed alone, as the corn, when very thick and high, is apt to retard its growth, and sometimes spoil the crop.

TRITICUM.

Wheat.

This remarkable genus consists of hardy herbaceous plants, mostly annuals or biennials, valuable for producing that most excellently useful grain called Wheat; are fibrous rooted plants, rising with grassy leaves and upright, tall, slender stalks, terminated by close spikes of chaffy flowers, succeeding to spikes or ears of corn.

Class and order, *Triandria Digynia*.

Characters.] CALIX, is a bivalvovous chaff, having the valves oval, obtuse and concave, containing sometimes many florets.—COROLLA, is small bivalvovous florets, as large as the calix, having the outer valve bellied and pointed and the inner one plane.—STAMINA, three hair-like filaments, with oblong forked antheræ.—PISTILLUM, a turbinated germen, two capillary reflexed styles, and plumose stigmas—PERICARPIUM none; one oval-oblong seed for each floret, obtuse at both ends, and wrapped up in the corolla.

There are many different species of Wheat, the principal sorts of which are,

¹ TRITICUM *hybernium*.

Winter or Common Brown Wheat.] Hath long spikes or ears, having four florets in each calix; and the grains of corn ranged in four rows, in an imbricated manner, with smooth, ventricose, or bellied chaff, almost without beards or awns.

This is commonly sowed in autumn to stand the winter; hence called Winter Wheat.

² TRITICUM *æstivum*.

Summer or Spring Wheat.] Hath spikes with bellied smooth calixes, ranged imbricatim, containing four flowers each, and are furnished with awns.

This sort is sometimes sowed in spring, as it ripens much earlier in summer than the other.

TRI

³ TRITICUM *turgidum*.

Turgid or Duck-bill Wheat.] Hath large thick turgid spikes with bellied hairy calixes, placed imbricatim, having four florets each, and mostly furnished with awns.

⁴ TRITICUM *Polonicum*.

Polonium or Poland Wheat.] Hath long spikes with naked calixes, having two flowers in each, which are long, and furnished with awns or beards.

⁵ TRITICUM *quadratum*.

Four-rowed Conical Wheat.] Having oblong conical spikes, armed with long awns or beards.

These are the principal species of Wheat generally cultivated, and which comprehend several varieties, differing somewhat in the form of their spikes and chaff, &c.

But the sort proper to cultivate for general use, is principally the Winter or common brown Wheat without awns; though all the sorts are also occasionally cultivated in different parts of the country.

All the sorts of Wheat may be considered both as annuals and biennials; for considered as annuals, that being sowed in the spring, they shoot up to stalk, and produce ripe corn the same year in autumn, and wholly perish soon after; and as biennial, that being sowed in autumn as practised for the Winter, and Turgid Wheat, &c. the plants rise the same year, stand all the winter, and shoot to stalk and corn in spring and summer following, and totally die in autumn, as soon as the corn is ripe.

These plants having spreading fibrous roots, they generally rise with several stalks, especially if they have room to spread, in which case they often produce from five or six to eight or ten stalks, each stalk terminated by a spike of corn.

They shoot up into stalk in May, and flower in June, consisting of numerous chaffy florets, collected into long close spikes at top of the stalks, each chaff or calix containing two, three, four, or more chaffy florets, and mostly placed imbricatim or over one another like scales of fish, all along the spike, some entirely without awns, and some with, either less or more, as in their description, and succeed to ripe heads of corn in July or August, fit to reap and stack up for use.

As to the propagation of Wheat, it is effected by seed sowed every year, principally in autumn, from August or September until November.

November, the ground being previously well ploughed for the reception of the seed, allowing generally two or three bushels to an acre; which for the general part is sowed broad-cast and harrowed in, and in some places in drills drawn by the drill plough, &c. a foot distance or more, which method of sowing requires a considerably less quantity of seed than the broad-cast sowing, and affords opportunity of horse-hoeing between the rows to kill weeds and stir the surface of the earth about the plants; which, as having more room generally grow stronger and produce a greater number of stalks on each root, than such as grow close in the broad-cast; though as the broad-cast sowing is the most ready and expeditious method, it is the most generally practised for sowing Wheat, and almost all sorts of corn.

TRIUMFETTA.

Triumfetta.

Comprises two tender exotics, a shrubby, and an herbaceous plant, natives of the Indies, and retained here in stoves for variety; rise with erect stalks several feet high, adorned with roundish leaves, and pentapetalous flowers in spikes at the ends and sides of the branches, succeeded by round bur-like capsules.

Class and order, *Dodecandria Monogynia*.

Characters.] CALIX, five spear-shaped deciduous leaves.—COROLLA, five linear, concave, retroflexed petals.—STAMINA, twelve or fifteen awl-shaped rising filaments, having single antheræ.—PISTILLUM, a roundish germen, a single style the length of the stamina, having a bifid acute stigma.—PERICARPium, a globular prickly capsule, having four cells, each containing two seeds.

There are two species, one a woody perennial, the other an annual, but the former of which is the sort commonly kept in the English gardens.

TRIUMFETTA *Lappula*.

Lappula, or Jamaica Triumfetta.] Rises with an upright woody stem, dividing upward into a few branches, and grows five or six feet high; roundish trilobed-leaves, emarginated at the base, and numerous small yellow flowers, collected in spikes at the ends of the branches.

It must be always kept in pots, and plunged in the bark-bed or the stove, and managed like other ligneous plants in the stove collection.

It is propagated by seed obtained from abroad, sowing it in a hot-bed, or in pots, and plunged in the bark-bed, where the plants will soon come up; which, when advanced one, two, or three inches high, should be planted in pots separately, and placed in the bark-bed of the stove to remain.

TROLLIUS, Globe Ranunculus.

Globe Flower or Locker Gowls.

They are hardy, herbaceous, flowery perennials for adorning the flower garden; have fibrous roots, crowned with divided leaves and upright annual stalks, two feet high, terminated at top with large polypetalous globular flowers.

Class and order, *Polyandria Polygynia*.

Characters.] CALIX, none.—COROLLA, about fourteen nearly oval connivent petals, and nine narrow, incurved, umbilicated nectariums.—STAMINA, numerous bristly filaments, having erect antheræ.—PISTILLUM, numerous germina, sitting close in a columnar form; no style, but the germen crowned by pointed stigmas.—PERICARPium, numerous capsules collected in a head, each having one seed.

There are only two species, both perennials, one an European plant, the other an Asiatic exotic, but both hardy enough to grow in the open ground all the year.

¹ TROLLIUS *Europeus*.

European Globe Flower, or Locker Gowls.]

Hath a black, fibrous, perennial root; sending up many roundish leaves, deeply cut into five segments, which are also divided and notched; upright stalks, about two feet high, dividing into branches upwards; each terminated by one large globular yellow flower, having the petals connivent or converging together, and the nectaria the length of the stamina.

² TROLLIUS *Asiaticus*.

Asiatic Globe Flower.]

Hath a fibrous perennial root, crowned with large divided leaves, upright stalks, near two feet high, dividing into branches, terminated each with one large saffron-coloured flower with spreading petals, and the nectaria the length of the corolla.

Both these plants flower in May very ornamentally, each flower being large and elegant, composed of many large concave petals; which in the first sort particularly, converge

verge or turn inward in a revolute manner, so as to give the flower a perfect globular form; hence is called Globe Flower, and is succeeded by plenty of ripe seed in autumn; but the flower of the second species *Trollius Asiaticus*, is not connivent but spread out and exhibit the nectariums and stamina; also of a fine saffron-colour, effecting an elegant singularity, and is sometimes succeeded by ripe seeds in our gardens, and by seed both the sorts may be raised, and they also multiply exceedingly by the root, which will be of many years duration, and produce flowers annually.

As therefore those plants, when in flower, effect a singular variety, they merit a place in every curious collection in the compartments of the pleasure-ground; and the season for planting them is in autumn when the leaves decay, or early in spring.

Remarking, however, that as they are natives of moist, shady, cool places, they are generally the most prosperous planted in such situations in gardens.

Their propagation is accomplished by parting the roots, and occasionally by seed.

By parting the Roots.—Autumn, when the leaves decay, is the best season to perform it, or early in the spring, taking up the roots, and divide them into several parts, not, however, into two small slips, and plant them either where they are to remain, or in nursery rows for a year; they will grow freely and mostly flower the summer following.

By Seed.—Sow it in a somewhat shady border in autumn or spring in shallow drills, and cover it almost half an inch deep, they will readily grow and be fit to plant out in summer, or towards autumn, in rows half a foot asunder, to remain six or eight weeks to acquire strength, then planted out finally.

TROPÆOLUM.

Indian Grass, commonly called *Nasturtium*.

Consists of herbaceous annuals or perennials, of very long, trailing, and climbing growth, in estimation for effecting variety in the pleasure-ground in summer, but require protection of a green-house in winter; grow with long stalks trailing many feet along the ground, or upon support, adorned with large roundish peltated or shield-shaped leaves, and numerous pentapetalous flowers all along the branches, of singular structure.

Class and order, *Oëandria Monogynia*.

Characters.] CALIX is monophyllous, horned, coloured, divided into five, acute, erect, spreading segments, and is deciduous.—COROLLA, five roundish petals, inserted into the divisions of the calix; the two upper ones fit close, and the three lower ones have oblong ciliated tails or claws.—STAMINA, eight short, declinated, unequal filaments, having erect, oblong, rising, quadrilocular antheræ.—PISTILLUM, a roundish, trilobate, streaked germen, single erect style, and a trifid, acute stigma.—PERICARPIUM, three roundish, convex, furrowed berries, having three roundish, furrowed seeds, with one side gibbous, the other angular.

There are only three species, two of which are common in the English gardens; considered principally as annuals, but if sheltered in winter in a green-house, will prove of a perennial nature, exemplified in the double *Nasturtium*.

The species are,

¹ *TROPÆOLUM minus*.

Minor or least Nasturtium.] Hath long trailing stalks, branching and extending several feet along the ground, or upon any support; large, roundish, or orbicular peltated entire leaves, of a grey colour, having the foot-stalk inserted into the center; and numerous yellow flowers at the axillas, all along the side of the stalk and branches; all the flowers having acuminate petals.

Varieties.] Pale yellow-flowered—Orange-coloured.

² *TROPÆOLUM majus*.

Major or greater Nasturtium.] Hath large, very long, trailing stalks, branching and extending ten or fifteen feet or more along the ground, or on support, garnished with large, orbicular, peltated leaves, almost indented into five lobes; having the foot-stalks inserted into the center; and numerous large yellow flowers at the axillas, all along the sides of the branches; with all the flowers having obtuse petals.

Varieties] Pale yellow-flowered.—Orange-coloured flowers.—Double-flowered, commonly called Double *Nasturtium*, retained generally as a green-house plant.

Both these species of *Tropæolum*, and respective varieties, flower in great profusion from June until autumn, or till killed by the frost; and the flowers are of singular form, being, in their single or characteristic state, composed of five unequal petals, the two upper

upper ones large, and the three lower ones narrow, with long tails joining together, and extended considerably behind; but in the Double Nasturtium the petals are multiplied exceedingly, even to the exclusion of the generative organs, and consequently no seed is produced; but in all the common single varieties the flowers are succeeded by great plenty of seed, contained in roundish, berry-like, green fruit. See the *Characters*.

These plants are all hardy enough to grow any where in the full ground all summer, until October or November, but are unable to endure the cold in winter.

They are generally deemed annuals, as they rise from seed in the spring, attain full perfection, flower, and produce seed the same year, and totally perish the ensuing winter, if in the full ground; but if any are raised in pots, and removed under shelter of a greenhouse, or good garden-frame, under glasses, at the approach of cold weather, they will stand over the winter, and may thus be preserved several years, as practised for the double *Nasturtium*; and, like that sort, be propagated also by cuttings, planted in the spring; though as they are easily raised in great abundance from seed sowed in spring or summer in the full ground, the preserving them over the winter is rarely attended to, except to a plant or two, by way of variety: and always for the double sort in particular, as not producing seed, nor if it did, would there be any certainty of continuing its doubleness by that method, is therefore propagated always by cuttings, and kept in pots to have shelter in winter.

All the sorts are cultivated in gardens, both as flowery plants, and for economical uses in their flowers and seed, for sallads and pickles; considered however as ornamental flowery plants, the common single sorts are dispersed in patches about the borders, and other compartments, and generally trained up to some support, or to run on any kind of treillage, railing, or the sides of arbors, or to be trained against fences, &c. sowing the seeds at once where they are to remain; some in patches, as aforesaid, two or three seeds together, near an inch deep; placing tall branchy sticks, when they come up, for the plants to run upon: others may be sowed in shallow drills, the same depth, along any kind of fences, as above, on which also to train the plants; and in some particular open

compartments may sow some to remain as trailers, and extend along the ground, agreeable to their natural growth.—In all of which methods, the seeds being sown any time in spring or summer, they will grow freely, and the plants will soon shoot out stalks and branches numerously, when they should be trained in the order intended, as hinted above.

But as to the double *Nasturtium*, this is always considered as a green-house plant; for although it will live in the open air all summer, like the other varieties, it cannot bear the winter's cold, so must be kept always in pots of light earth, and placed among the green-house exotics, placing sticks for their support: thus they will remain ever-green, and effect variety very agreeably, and produce abundance of flowers all summer and autumn; also often moderately in winter; observing during the winter to allow them but very little water, as too much moisture would rot them at this season of the year.

Considered as economical plants, or esculents, before noticed, the common single varieties of both the species are often cultivated for their flowers and fruit, the former for sallads, and the latter to pickle; for the flowers being of a warm, agreeable relish, are by many greatly esteemed to mix in sallads, also as garnish to sallads, when sent to table in form; and are likewise in great estimation for garnishing dishes of meat, &c. and as to the fruit, this, when young and green, is an excellent pickle, and for which purpose particularly the plants are cultivated in many gardens.

When therefore it is intended to cultivate these plants as esculents, for the flowers and fruit, they may be sowed in the kitchen-garden in April or May, either in patches or in shallow drills, an inch deep; and when the plants come up, place branchy sticks for their support, and they will thus supply you with abundance of flowers and fruit from June or July until October.

Method of Propagation, &c.

The method of propagation is by seed annually, for all the common single varieties, sowing it in spring, the end of March, or in April or May, in patches or drills, in the places where the plants are to remain, as above observed.

But

But the double *Nasturtium* not producing seed, and being only a variety, is propagated by cuttings of its branches, and by which it will always retain its double property: planting the cuttings any time from April until July, in pots of light earth, and placed in the shade, giving moderate waterings occasionally; or those planted early may be plunged in any moderate hot-bed, to facilitate their rooting more effectually.

TROWEL. A Garden Trowel.

A Garden Trowel, made of iron, in a hollow or scooped form, is a handy useful implement in taking up and transplanting numerous sorts of small plants and bulbous roots; planting in pots; sowing in patches, &c. and various other similar light works in gardens.

This kind of Trowel being of iron, from twelve to six inches long in the plate, and half as broad, hollowed like a scoop, and fixed on a short handle, to hold with one hand, proves a most convenient handy tool in a variety of garden operations; for being hollowed semicircularly, it is remarkably handy in removing many sorts of small plants with a ball or lump of earth whole about their roots, so as not to feel their removal; lifting bulbous flower roots after the flowering is past in summer; planting bulbs in patches or little clumps about the borders; as also for digging small patches in the borders for sowing hardy annual flower-seeds; likewise for filling mould into small pots in planting any sort of plants therein; stirring the surface of the mould in pots, and fresh earthing them when necessary. It is also most useful for filling in earth about plants in hot-beds, and under frames, and any small compartments where a spade cannot be readily introduced. And such a Trowel is likewise very convenient for pointing over or stirring the ground between rows of small close-placed plants in beds or borders, &c. and for many other purposes occasionally.

But to suit the several purposes more effectually, it would be proper to be accommodated with two different sizes of scooped Garden Trowels, viz.

A common larger one for general use, being about twelve inches long in the plate, and six broad, narrowing gradually to the bottom.

A smaller one for particular purposes about six or eight inches in the plate, and

four broad, narrowing pretty considerably towards the bottom, to introduce between small plants.

They may be had of different sizes at most of the ironmongers where they sell spades; or any common smith may easily make them.

TRUNCUS, Trunk, the main Stem of trees and plants.

The Trunk rises immediately from the root, and may be deemed the stock or main body of the vegetable, as it multiplies into branches, buds, leaves, flowers, and fruit. See **CAULIS**.

The Trunk or Stem is of seven sorts, viz.

Caulis.—The most common species of Stem, both of trees and herbs, or such as produces and supports the leaves, flowers, and fruit. See **CAULIS**.

Scapus.—Is an herbaceous, naked Stem, that elevates the fructification only, and not the leaves, as in *Narcissus*, *hyacinthus*, &c.

Culmus.—A straw or haulm, being the Trunk or Stalk peculiar to the grasses and corn, bearing both leaves and flowers; and sometimes flowers and no leaves.

Frons.—The Trunk of the palms and fern tribe, being a compound Stem, formed of a branch and leaf blended together, and frequently also the flower and fruit.

Stipes.—The Trunk or Stem of the mushroom, and other *fungi*.

Pedunculus.—A peduncle, or flowering-stalk, rising sometimes from the root, but mostly from the branches, elevating the flowers and fruit, but not the leaves. See **PEDUNCULUS**.

Petiolus.—A leaf-stalk bears the leaves only, and not the flowers. See **PETIOLUS**.

TUBEROUS ROOTS, such as consist of one or more swelled or knobbed tubers, of a solid fleshy substance, as in the turnep, anemone, potatoe, &c.

TUBUS, a Tube or Pipe, being the lower, narrow, hollow part, of a monopetalous flower.

TULIPA. Tulip.

This most noted genus furnishes a grand collection of bulbous-rooted flowery perennials of admirable beauty and elegance, consisting of about two or three species, one of which in particular produces most beautiful and superb flowers, and comprehends a prodigious family of varieties, even to the amount of thousands, having all large bulbous roots, crowned with long, broad, spear-shaped

shaped leaves, and erect flower stalk, from half a foot to a yard high, terminated with large liliaceous, bell-shaped flowers.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, none.—COROLLA is bell-shaped, and composed of six large, oblong, oval, concave, erect petals.—STAMINA, six shortish, awl-shaped filaments, having oblong, quadrangular, erect antheræ.—PISTILLUM, a large, oblong, trigonal germen, without a style, and crowned by a triangular three-lobed stigma.—PERICARPIUM, a trigonous, trivalved, trilocular capsule, containing many plane or flat semicircular seeds, resting upon one another in a double order.

There are three species, two of which only are known in the English gardens; and one of these in particular (the *first sort*) is famous for the extraordinary beauty of its large noble flowers, most elegantly striped and stained with a vast diversity of rich colours, in a thousand various forms; constituting so many different varieties, all very great ornaments to our gardens in April and May.

¹ TULIPA *Gesneriana*.

Gesner's Turkey Tulip of Cappadocia, or common Garden Tulip.] Hath a large, oblong, tunicated, solid, bulbous root, covered with a brown skin, sending up long, oval, spear-shaped leaves; an upright, round stalk, from half a foot to a yard high, garnished with a few leaves, and its top crowned with a large bell-shaped, erect, hexapetalous flower, of almost all colours and variegations in the different varieties.

Varieties] Early Dwarf Tulip (*Præcocea*), rising with short stalks, from five or six inches, to ten or twelve high, with smallish flowers.—Tall late-flowering or common Tulip (*Serotina*) rising from about half a yard to two or three feet high, with large well-formed flowers.—Double Tulip, rising a foot or two high, or more, having large double flowers.—Whole-blowing, or self-coloured Tulip, being all of one original colour, either purples, reds, violets, greys, copper-colours, yellows, &c. which gradually break into numerous variegations.—Variegated Tulip, comprising innumerable varieties, in respect to the different colourings, variegations, and stripes.

Each of the above principal varieties of this species, comprehends numerous inter-

mediate ones, in respect to the colours and variegations of the flower; each however is originally all of one colour, especially seedlings, which, when arrived to a flowering state, each separate flower is either wholly red, purple, violet, grey, brown, black, or yellow, &c. without any variegations or stripes, consisting of self-coloured flowers, with white bottoms; self-coloured flowers with yellow bottoms; and some also with blue, purple, and blackish bottoms; all of which, whilst they retain this original same colour, are, in the florists' language, called *Whole Blowers* or *Breeders*, because each flower is wholly of one self-colour; and the roots being planted a year or two in prepared soils, to breed, or dispose them gradually to produce flowers that break from the original self-colour into variegations and stripes, in various different forms; and are then called *Breakers*, each different variegation constituting a distinct variety; consisting of flowers with—white bottoms, broken with brown stripes, with blue stripes, violet stripes, rose stripes, red stripes, &c. separated by streaks of white and other colours, variously disposed.—Yellow bottoms, broken with different reds, crimsons, and golden-yellow flakes, and various other colours.—Some also with blackish purple bottoms, &c. broken with stripes of dark colour, yellow, and tincts of red; so that in these sorts of Breakers, or variegated Tulips, with white and yellow bottoms particularly, there are also, white and red-striped flowers—white and purple-striped—white and violet-striped—white and rose-striped—white and brown-striped—violet and white-flaked—red and white-flaked—red and yellow-flaked—brown, yellow, and red-flaked, and numerous other intermediate variegations and stripes, variously disposed in an endless diversity.

Thus the Breakers or variegated Tulips are diversified with an infinity of colours in innumerable different ways, forming so many different varieties, the principal of which are by the florists distinguished by pompous names, either of some great personages, eminent florists, places of their original growth, &c. but as vast numbers of new varieties are annually obtained from seedlings, in so many different places, distinguished by various new names, and old ones rejected; and often the same flower, with a different name

imposed by different florists, it would be impossible to give any correct list here of the names of such numerous varieties, so often changing every where.

² TULIPA *Sylvestris*.

Wild European Tulip.] Hath an oblong bulbous root, sending up long, narrow, spear-shaped leaves; and a slender stalk, supporting at top a small yellow flower, nodding on one side, having acute petals.

Both these species of *Tulipa* are hardy perennials, durable in root, or at least, although the old bulb decays annually, it perpetuates its species by off-sets, and is annual in leaf and stalk; which rising from the bulb early in the spring, arrives to a flowering state in April and May, each plant having only one flower, supported on the top of the naked stalk, without any calix or cup, and consists of six large petals, three within and three without, mostly in an erect position; the whole together forming a sort of large cup, either bell, or egg-shaped; though the Double Tulip have the petals multiplied in an indeterminate number. All the varieties are succeeded by plenty of ripe seed in July and August, contained in an oblong capsule of three cells, having the seeds placed on each other in double rows, (see the *Characters*); and by the seeds numerous new varieties may be raised; which however will not attain a flowering state till they are seven or eight years old, and after that will require two or three years or more to break into variegations, when the approved varieties may be marked, and increased by off-sets of the root, as directed in their *Propagation*.

It is remarkable, that although the Tulip may be said to be a perennial plant, yet, after the bulb arrives to a flowering state, the same individual old root or bulb does not always remain to flower again, but gradually wastes away, as may be observed by its relics at the lifting season; but, however, previous to its dissolution, it affords from its sides a supply of suckers or off-set young bulbs, to perpetuate the species; and one of which being large, and similar to the parent bulb, is capable of flowering equally strong next year; so that at the end of many years, what is often still supposed to be the same individual bulb, is in reality another in every respect.

Remark, that of the two species of Tulip, the first sort, *Tulipa Gesneriana*, or common

Garden Tulip, and its vast train of varieties, is the sort so generally cultivated for the ornament of our gardens, and so much admired by all for its great variety and beautiful appearance, grows freely in the open ground in any common soil of a garden, and proves a very great decoration to the beds and borders of the pleasure-ground, for six weeks or two months in spring, by different plantings of early and late sorts; planting the principal part in autumn, and the rest towards Christmas, and in January or February; the autumn plantings will come earliest into bloom, and flower the strongest; and the others will succeed them in flowering; observing that in summer, when the flowering is past, and the leaves and stalks assume a state of decay, the bulbs of the choicest varieties are generally taken up, the off-sets separated, and the whole cleaned from filth; then put up in the dry till October or November, and then planted again for the future year's bloom.

As to the second species, *Tulipa Sylvestris*, it having but little beauty, in comparison with the others, is not near so generally known or cultivated; though it was formerly in estimation, before the Turkey Tulip was so general; and is still to be seen remaining in many old gardens; and it also deserves culture in modern ones, both for its early flowering, and to increase the variety, in concert with the common Tulip, and other spring flowers, in the open borders.

However, all the sorts of Tulips being very hardy perennials, they will prosper in any common soil of a garden, and are admirable fine ornaments for adorning the borders and flower-beds; the roots being planted in autumn, the more ordinary sorts in rows or patches, along the front of borders, and the fine varieties in beds by themselves, as hinted in the articles *General Observation* and *Their general Culture*.

Arrangement and Merit of the different Varieties.

As we formerly observed, the first species, Common Tulip, &c. is the florist's delight, and merits universal estimation for its vast profusion of beautiful varieties, which may be divided into two principal classes, viz.

1. Early or Dwarf Spring Tulips (*Præcoceæ*.)
2. Late flowering tall Tulips (*Serotina*.)

Remark

Remark however, of these two classes, that although the first class (early Tulips) is in great estimation for its early bloom and lively colours, yet the second class is in still higher repute for its stately growth and great diversity of rich colours, and profusion of varieties; and is the most universally cultivated. — See each class as below.

Early Tulips. — The early Tulips are among florists distinguished by the appellation of *Præcoces* (early), because they flower early in the spring, a month or more before the others; are much shorter stalked, and the flowers smaller; but are in great reputation for their early bloom, and their gay lively colours, both of self-colours, and broken into flaked variegations; such as reds, crimson, scarlet, carnation, violets, purples, yellow, &c. with flowers of each, edged and flaked with red, yellow and white, in many diversities.

That the bulbs of these early sorts being planted in any good, light, rich earth, in a warm situation, in the end of September, or any time in October or November, in yard-wide beds, in rows, six or eight inches asunder, and three or four inches deep, they will rise early in the spring, and arrive to flower in March, continuing till the late Tulips come into flower.

Though as the early dwarf sorts are well adapted for forcing, they may still be blowed earlier, by either planting the roots in pots or boxes in autumn or winter, and place them in a stove, or a hot-bed, whereby they may be forwarded into bloom in January and February, or earlier; and a succession continued till the natural ground-bloom arrives; or may place a quantity of bulbs upon phial-glasses of water, in autumn or winter, one bulb in each glass, and place them either in any warm, light room of a house, near the windows, or in a green-house or stove, by which they will also flower very agreeably in winter, and early in spring; they being the best adapted sorts of Tulips for all these methods of blowing.

They are sold by the seedsmen and nurserymen in great collections of different sorts, by names, chiefly Dutch or French, such as the *Duc van Toll*, &c. as may be seen in most of the flower-catalogues.

Late-flowering Common Tulips. — This class is denominated late-flowering, and by

the florists called *Serotines*, because they blow later in the spring, a month or more, than the *Præcoces*, i. e. not coming into flower before the end of April, May, and June; are all of tall growth, supporting large flowers, and furnish an almost endless variety in the vast diversity of colours, after they break from whole-blowers into variegations and stripes, exceeding all others of the Tulip kind in beauty and elegance of flower.

Tulips are also subdivided into other classes, such as Whole Blowers, and broken Tulips.

Whole Blowers or Breeders. — These are seedling Tulips, having flowers wholly of one colour; they being raised from seed to a state of flowering, the flowers remain two, three, or more years of one self-colour, before they break into variegations; which are also divided into classes, according to the Dutch florists called, — 1. *Bizzares*; being generally almost of a brown copper colour, having at the bottom a small round spot, either yellowish, or black mixed with a little yellow, which when broken into different colours, become *Bizzares* with yellow bottoms. — 2. *Violettes*, being either all of a purple-violet, pale-violet, grideline, cherry-crimson, or red; having the spot at bottom, either a clear white, or blackish-grey mixed with a little white; and their production when broken into different colours become Tulips with white bottoms, called by the Dutch, *Bybloemens*.

Broken or Variegated Tulips. — Such that are broken from the self original colour of the whole-blower or breeding Tulips, into variegations and stripes of different colours; observing, they generally break into different variegations according to that of the former self-colour; generally however, either wholly expelling the original self-colour of the breeder, or leave but very little remains thereof, which is a desirable requisite in these kind of flowers among professed florists; and when thus broken or variegated with different colours, they exhibit themselves variously mixed, striped, flaked, feathered, marbled, spotted, edged, &c. a thousand different ways in an admirable manner; and are by the florists divided into the following classes, called by the Dutch

Baguette primo. — Tulips with white bottoms, striped with brown, &c.

Baguette rigaut.—Tulips with a white bottom, broken with dark-brown stripes, &c.

Bybloemens.—Tulips with a white bottom, striped with violet and blackish brown, &c. —White bottom Tulips striped with rose-colour, vermilion, and ruby.

Bizzares.—Yellow bottom Tulips, striped with various colours.

Among florists the principal properties requisite in the above classes of Tulips to constitute a fine flower, are—The stem must be tall, especially of the *Serotines*, from half a yard, to two or three feet high, or more, being proportionably thick and strong; the flower large, composed of six petals, as in the characteristic state, these being broad, thick, rounded at top, and stand firmly erect without turning much inward or outward, but so as to cup well, and give the flower a regular form. The colours and stripes of the flower must be bright, arising unmixed, regularly and distinct from the bottom with but little or none of the original self-colour remaining.

The colours in greatest estimation in the broken tulips, are the blacks, golden-yellows, purple violets, rose, and vermilion, each of which being variegated various ways; and such as are striped with three different colours distinct and unmixed, with strong regular streaks, with but little or no tinge of the breeder, may be called the most perfect Tulips.

Though it is rare to meet with a Tulip possessing all the properties, yet have sufficient perfection to render them of high estimation as fine flowers.

As to the manner of obtaining this wonderful variety of colours in Tulips, it is often accomplished principally by nature alone, which however is sometimes assisted and forwarded by some simple operations of art, such as, that in the first place, when the seedlings bulbs of the whole-blower or breeder are arrived to full size, and have flowered once, to transplant them into beds of any poor dry barren soil, in order that by a defect of nutriment in the earth, the natural luxuriance of the plant may be checked, and cause a weakness in their general growth, whereby they generally in this weakened or infirm state, gradually change and break out into variegations,

some the first year, others not till the second or third; and according as they are thus broke, they should be planted in beds of good earth, as hereafter hinted.

Another method to assist nature in effecting the marvellous work of breaking the breeding Tulips into diversified colours, is to make as great a change as possible in the soil; if they were this year in a light poor soil, plant them the next in a rich garden mould, and another year in a compost of different earths and dung; or transplant them from one part of the garden to another, or into different gardens, &c. or from one country to another; all of which contributes in assisting nature in producing this desirable diversity of colours and variegations.

The double Tulip is also a variety of the common Tulip, is very beautiful, though not in such estimation among the florists as the common single variegated sorts; not possessing such a profusion of variegations in the colours and regularity of stripes; they however exhibit an elegantly ornamental appearance, as they rise with an upright, tallish, firm stem, crowned with a very large double flower composed of numerous petals, multiplied in several series one within another like a double peony, but far more beautiful in their diversity of colours, variegations, and stripes of white and red, or yellow and red, &c. so that they highly deserve culture both in beds alone, near the other sorts, to increase their variety; also to plant in patches about the borders, in assemblage with the late variegated Tulips, as they blow nearly about the same time, i. e. April and May.

General Observations.

As we before hinted, all the varieties of Tulips succeed in the open ground, in beds or borders of any common garden-earth planted as hereafter directed.

The roots are sold in full collection, consisting of numerous varieties, at most of the nurseries and seedsmen's, who both propagate them themselves by off-sets and seed, and import vast quantities annually from Holland; the Dutch being famous for raising the grandest collections of the finest Tulips, and other bulbous flowers, in the greatest perfection, for the supply of almost all the other European gardens; distinguishing every variety

variety in their vast collections by some pompous name or other, as before observed, arranged in regular catalogues; charging prices in proportion to their estimation, which formerly was so great, among the Hollanders themselves in particular, that there are accounts of a single root being sold for from two thousand to five thousand five hundred guilders; however they are now more plentiful, and are sold at from five or ten shillings to so many pounds, per hundred, and sometimes considerably more for very scarce capital sorts: and the most eligible season to buy in a collection, is early in autumn; i. e. any time from August or September, till November.

And as to the season for planting them is in autumn; about October and November is the most proper period for putting in the main collection, to blow in April and May following; but, in order to have a later bloom by way of succession, some may be planted in December, January, or February; though they will not flower near so strong as those planted in autumn or the early part of winter.

But the early Tulips should generally be allowed a warm, sheltered, sunny situation, on account of their early rising and flowering in the spring, whilst the weather remains cold and pinching; generally also always kept separate and planted in beds by themselves, not promiscuously with the late tall Tulips; for as their stature and time of flowering are different, they would not distinguish themselves to proper advantage: may also distribute some in the fronts of warm borders in patches, in concert with anemones, ranunculuses, &c.

However, as to the late Tulips, or *Serotines*, they may be planted in any of the common beds or borders, as they will be in no danger from any inclemency of weather.

But the fine or more valuable sorts in general, both early and late kinds, are commonly deposited all together in beds by themselves; the early and late kinds in separate beds, in rows eight or nine inches asunder, that they may exhibit a grand blow together, and that they may be readily defended if necessary, especially when in bloom, from heavy rains, and the scorching sun, occasionally.

Though as to the inferior sorts, they may be distributed about the common borders in

patches, three or four roots in each, in which they will have a fine effect when in bloom.

Their General Culture.

Having given the foregoing preparatory hints, will now proceed to the general culture of the plants.

First, with regard to soil and situation, it has already been suggested, that all the varieties of Tulips will grow very freely in any common light mould that lies dry in winter, generally preferring an open sunny exposure; though nothing can hurt a Tulip but too wet soils, so that if the situation of the ground in any place proves naturally low and wet, the beds must be raised a few inches above the common level; though the florists often prepare studied composts to form beds for their finest Tulips (see COMPOSTS.) However, to save trouble and expence, they will be found to succeed in any good garden-earth; only observing it is not adviseable to plant the fine sorts particularly, more than one or two years together in the same bed or earth, without making some alteration in the soil, either wholly or in part, by removing some of the old, and adding an equal portion of fresh earth, either from any of the kitchen-garden quarters, or any compost heap, or elsewhere, that is good: and wheel away the old earth to supply the place of the new; and thus by renewing the soil less or more, the Tulips may be expected always to blow stronger and fairer in proportion; though this is only advised for the finest sorts that are planted together in beds; those intended to decorate the open borders, may be planted any where as the soil happens, and they will also flower very well.

But to proceed in preparing the beds for the choicer sorts, as formerly observed: let the ground be well digged one or two spades deep, and form the beds three or four feet wide, moderately high in the middle, and of a rounding form, with wide alleys between bed and bed; and rake the surface of the bed even, ready for the reception of the bulbs.

Then, when the beds are thus prepared, proceed in a dry day to plant the bulbs or Tulip roots, in rows, either by bedding-in, drilling, or dibble-planting (see PLANTING), marking out lines lengthways the bed, eight

or

or nine inches asunder, in which plant the roots singly, four or five inches deep, and six distant in the lines; and when they are all thus planted, rake the surface of each bed smooth.

Those you intend for the open borders, may either be planted in a line a foot from the edge, or disposed in patches or little clumps, three or four roots together, in a patch of six or eight inches diameter, some patches forward, others more backward to effect a greater diversity.

After the Tulips are planted, they require no care till the following spring and summer; as being in no danger from the rigours of winter, they do not want covering; and in spring, no more is required than keeping them clean from weeds; except you chuse to protect the buds of the choicer kinds in the beds, by covering them in cold nights with mats, supported on hoop arches, though it is not absolutely necessary; or when the bedded Tulips are come into flower, if you would protect them to preserve their beauty as long as possible, it may be effected by shading them from the noon-day sun, heavy rains, and tempestuous winds, with a shade or awning of canvass or mats erected across the beds, which by some is made high like a tent, to walk under and view the flowers at pleasure: though we would also observe that these flowers will blow in great perfection without all this care of covering; only that by protecting some of the finest sorts growing in beds, the blow may be prolonged a week or fortnight longer in full beauty, than those that are fully exposed; being careful to remove all covering as soon as ever the flowers begin to fade, to admit the free air, rains, &c. for the benefit of the roots.

When however the flowering is past, or as soon as ever the flowers are faded, it is proper to cut off the head or seed-vessel of the fine varieties particularly, that it may not rob the root of any nourishment, which will thereby encrease more considerably in size and strength.

Though when intended to save seed for sowing, some heads of the stoutest plants must be left to ripen.

The next care is in June, when the leaves and flower-stem are decayed and withered, determining that the roots have ceased growing, and draw no nourishment from the

earth; at which period of rest is the time for lifting or taking them up out of the earth, in order both to separate the encreased off-sets, and to reserve them out of ground till autumn, that they may have some respite from growth, as well as to be planted in fresh-prepared beds to promote the merit of the future year's bloom; and which work of lifting these bulbs should be practised annually at the above period to all the choicer kinds, in the beds, and also to the more inferior sorts in the borders, &c. at least every other year, if they appear to have encreased by off-sets considerably. See BULBUS.

Therefore, at the above period, of the decay of the stem and leaves, taking the opportunity of dry weather, proceed with a garden trowel to dig them up carefully one and one, with all the off-sets to each; spreading them in a dry, airy, shady place, here remaining two or three weeks out of the sun and wet; but exposed to the free air, they will gradually dry and harden; then detach the off-sets and all adhering earth, and the outer decayed skins or husks that are the relics of the old bulb; after which expose them again in the same place to dry, and harden effectually; then put them up safe in the dry, in boxes, the large bulbs and the off-sets separately, to remain till the time of planting them again arrives.

Observing, the flowering bulbs are to be planted as has been already advised, and the off-sets in separate beds, by way of a nursery, to remain to acquire due size and strength to flower, then managed as the other flowering bulbs. See BULBUS.

Thus far concludes the principal general culture of the great family of Tulips; we shall now next exhibit the general method of propagation.

Method of Propagation.

All the sorts of Tulips are propagated abundantly by off-sets of the root annually, and are also raised from seed to gain new varieties.

By Off-sets.—The old bulbs encrease fast by off-sets bulbs from their sides, and which should generally be separated annually, especially those of the fine Tulips; and the season for this is in June, when the flower is past, and the leaves and flower stems begin

to wither; then take up the roots wholly, and separate the small encreased off-sets from the larger bulb, planting the off-sets in nursery beds, in drills six inches asunder, and three deep, to remain a year or two to grow to a flowering state; managing the flowering bulbs as already directed.

Thus by off-sets may all the sorts of Tulips be propagated in great abundance, and by off-sets every approved sort continued always the same, so that being in possession of any new or approved varieties, may with one soon encrease the stock by off-sets annually, and will generally produce flowers similar to their respective parent bulb. See *BUBUS*.

By Seed.—This is a most tedious undertaking, as the Tulip, from the time of sowing the seed, is seven or eight years before it produces flowers; and after all, they at first appear only self-colours, before explained, often requiring two, three, or more years longer before they break into different colours or variegations, so that the tediousness of raising seedling Tulips to a flowering state, often deters many from the undertaking. It is however, the method by which all the fine varieties of Tulips were first obtained, and new varieties are still annually gained, as many persons sow some every year, in expectation that after the first six or seven years a new shew of flowers will be produced, and out of which many new varieties will annually discover themselves in each parcel; and it is by this process the Dutch are famous for furnishing such an infinity of fine varieties, supplying almost all other countries in Europe.

Therefore, for the satisfaction of those who may incline to embark in this tedious undertaking, we will exhibit the method of sowing and rearing the seedlings to a flowering state.

The seed for this purpose should be saved from some strong-blowing plants, that are always fully exposed to the free air, suffering them to stand till the heads or seed-pods and seed are duly ripened; then gathered in a dry day, and laid by upon a shelf, &c. till September, the season for sowing them; which may be performed either in a bed of any good light mould, in the full ground, exposed only to the morning sun; or in boxes or large pots of light earth, and

placed in a similar situation: observing, if in beds, to sow the seed in shallow drills, and cover it near an inch deep; and if in boxes or pots, sow it on the surface, and cover it the same depth; they will come up the following spring with fine grass like leaves; at which time be careful to keep the young plants very clean from weeds; likewise give frequent moderate waterings in dry weather, continuing it occasionally as long as they retain their green leaves in a growing state, and not after; and when the leaves decay, clear the surface carefully from weeds and moss, if any, and directly sift a little fresh mould over the surface half an inch deep, which is all that is required till next year; when the plants will rise with much stronger leaves, in proportion to the encreased growth and strength of the bulbs; which, when their leaves again decay in summer, should be taken up and planted in nursery beds, in drills two inches deep, and the same distance in the lines, with the rows four or five inches asunder; here to remain and take their growth for two years, keeping the beds clean from weeds, and sift some fresh earth over the surface every autumn, half an inch deep; then, in the second summer, when their leaves decay, the roots being by that time considerably improved in growth, should be again taken up, and planted in a fresh prepared bed, in drills three or four inches asunder, in which to remain two years longer; then at the decay of the leaf, should be again transplanted into fresh beds, in rows as before; where let them remain to blow, afterwards ordered as the other flowering bulbs of Tulips, in the manner already shewn.

Observe however, when they are in full flower, to examine them with attention, in order to mark such of them as discover the best properties, that they may be separated from the others at the proper lifting season, and replanted in beds by themselves for breeders; removing them annually at the proper season into different beds of opposite or contrary soils, as before suggested; such as one year in poor hungry earth, the next in a much richer mould; and so continue till they break into variegations and stripes of different colours.

Thus each year as the flowers break into colours, mark them in order to be taken up, and

and ranked with the other improved varieties.

TURNERA.

Turnera.

Comprehends tender exotics of somewhat ligneous growth, natives of the hot parts of America, and retained here in stoves for variety; rising with erect stalks, dividing into branches; adorned with oval and spear-shaped leaves, and pentapetalous flowers at the sides of the branches.

Class and order, *Pentrandria Trigynia*.

Characters.] CALIX, is monophyllous, bell-shaped, tubulous, divided into five segments, and is permanent.—COROLLA, five heart-shaped, pointed, plane-spreading petals, with narrow claws, inserted into the tube of the calix.—STAMINA, five awl-shaped short filaments, having acuminate erect antheræ.—PISTILLUM, a conical, germen, three slender styles, and multifid capillary stigmas.—PERICARPIUM, an oval, trivalvular, unilocular capsule, containing many oblong obtuse seeds.

TURNERA *Ulmifolia*.

Elm-leaved Shrubby Turnera.] Rises with ligneous, shrubby-like, branchy stalks, six or eight feet high; garnished with oval, spear-shaped, rough leaves, having two glands at the base; and yellow flowers sitting close to the foot-stalks of the leaves towards the upper part of the branches.

Variety.] Narrow Elm-leaved Turnera.—(*Angustifolia*).

This species and variety are somewhat of a biennial nature, as that after being raised from seed, &c. they are frequently apt to go off the second or third year; though they also often prove of longer duration. Observing, that as they are tender exotics from South America, they must be kept always in pots, and placed constantly in the stove.

They begin flowering in June, continuing in succession very ornamentally all summer and autumn, succeeded by ripe seeds in September.

Both the varieties are easily raised from seed, sowed in the spring in pots, and plunged in the bark-bed, or any other hot-bed, under glasses; and when the plants are come up, two, or three inches high, plant them separately in small pots, which plunge

also in the stove bark-bed, and order them as other exotics of similar temperature.

TUSSILAGO.

Colt's-Foot.

It consists of low, hardy, herbaceous, creeping-rooted perennials, for variety and medical uses, remarkable for producing their flowers before their leaves, rising with low erect stalks only a few inches high; roundish, heart-shaped, and oval leaves close to the ground, and the stalks terminated by small compound flowers, some radiated, and some without a radius.

Class and order, *Syngenesia Polygamia Superflua*.

Characters.] CALIX, a compound flower, having a cylindrical cup composed of fifteen or twenty linear, spear-shaped, equal squama or scales.—COROLLA, a variously compound flower; being either all hermaphrodite florets, or hermaphrodites only in the disc, funnel-shaped, and four or five-parted at the brim; and the female florets, where any, are narrow, tongue-shaped, and entire.—STAMINA, in the hermaphrodites, five very short hair-like filaments, having cylindric antheræ.—PISTILLUM, a short, germen, thread-shaped style, longer than the stamina, which in the females is bifid.—PERICARPIUM, none; a single seed in each floret, which is oblong, compressed, and crowned with a hairy down.

There are about nine species of *Tussilago*, the most material of which are the following, consisting of the common *Tussilago*, and five other species.

TUSSILAGO *Farfara*.

Farfara, Common Tussilago, or Colt's-foot.]—Hath fibrated, creeping, white, perennial roots; sending up single, thickish, imbricated stalks, five or six inches high; that are uniflorous, or each crowned with only one largish, pale-yellow, radiated flower, appearing in March and April before the leaves; and when the flower is past, the leaves arise, being large, roundish, nearly heart-shaped, angulated, indented, and hoary.

This species inhabits most situations every where in Britain, and most parts of Europe in great plenty, creeping and multiplying exceedingly by the roots; and is not much cultivated in gardens.

It

It, however, is worth culture in the herbaceous collection, both to effect variety among the spring flowers, in patches in the borders, where it will exhibit an agreeable singularity; and may also be cultivated as a medicinal plant, its leaves being often used in decoctions, and as a principal ingredient in the British Herb Tobacco.

It is one of the *filius ante pater* tribe, i. e. son before the father; because the flowers always arise before the leaves.

² *TUSSILAGO Alpina.*

Alpine or Mountain Colt's-Foot.] Hath a creeping perennial root, sending up an almost naked stalk, only three or four inches high, which is uniflorous or crowned with only one purple flower, in March and April, and almost round, or orbicular heart-shaped, crenated leaves, downy underneath.

Variety.] Round hoary-leaved.

³ *TUSSILAGO Anandria.*

Anandria, or Siberian Colt's Foot.] Hath a creeping, perennial root sending up erect somewhat scaly stalks, three or four inches high, crown each with one purplish flower early in the spring; and oval lyre-shaped leaves close to the ground.

⁴ *TUSSILAGO Petasites.*

Petasites, Tussilago Major, or Common Butter Bur.] Hath a thick, fleshy, creeping, perennial root; sending up thick hollow stalks; six inches high, crowned with several purplish flowers, collected in an oval thyrse or spike, having all the florets floscular hermaphrodites, and large roundish heart-shaped leaves, from one to two feet broad; grows wild in moist meadows, &c. in England and other parts of Europe, and is a medicinal plant.

⁵ *TUSSILAGO Hybrida.*

Hybridian German Tussilago, Greater Colt's

Foot, or Long-stalked Butter Bur.] Hath a creeping perennial root; sending up stalks six or eight inches high, crowned with an oblong thyrse or spike of flowers, having many naked, floscular, female florets; and large leaves arising after the flower is past.

⁶ *TUSSILAGO alba.*

White Alpine Tussilago, or smaller Butter Bur.] Hath creeping perennial roots; slender stalks, three inches high; crowned with a flat thyrse or spike of white flowers; and largish leaves, arising after the flowers are past.

All these species of *Tussilago* are very hardy perennials, of great duration in root, but annual in stalk and leaves, and mostly all possess the singularity of producing their flowers before the leaves; the flowers rising immediately from the root on low tender foot-stalks, having in some sorts only one flower at top; in others, several collected in a thyrse or close bunch, generally all appearing early in spring; and when the flowers fade, the leaves arise directly from the root, on short foot-stalks near the ground, continuing till autumn, then decay; and the roots remaining, send up flowers and leaves again every spring; producing also abundance of downy seeds early in summer.

These plants may be employed in gardens for variety, and although they naturally affect moist situations, they will succeed almost any where, and will encrease abundantly by the root, be of many years duration, and exhibit their flowers annually in spring.

But the *Common Tussilago*, &c. may also be cultivated in beds as medicinal plants.

They are all very easily propagated by parting the roots in autumn or spring, the smallest slip will readily grow, and soon multiply.

U.

ULEX.

Furze, Gorse, or Whins.

They are shrubby, thorny plants, consisting of two species only; one sort, *Common Furze*, is a noted, hardy, European shrub of heaths and commons, sometimes cultivated for variety in shrubberies, and occasionally to form field hedges; and the other is a tender exotic shrub of Africa, requiring shelter of a green house here in winter; are both of very branchy, bushy growth, five or six feet high, remarkable for their evergreen shoots and branches, armed with strong evergreen spines; small, thinly placed, deciduous leaves, and numerous papilionaceous flowers all along the sides of the young branches.

Class and order, *Diadelphia Decandria*.

Characters.] CALIX, two oval, oblong, concave, permanent leaves.—COROLLA, is papilionaceous, with five petals, having a large, oval, heart-shaped, emarginated vexillum; two short, oblong, obtuse wings, and a bipetalous carina or keel.—STAMINA, ten diadelphous filaments, having simple antheræ.—PISTILLUM, an oblong cylindric germen, a rising style, crowned with a small obtuse stigma.—PERICARPIUM, an oblong, turgid, bivalvular, unilocular pod, containing roundish seeds.

There are only two species, both of shrubby growth, as before suggested; one of which is hardy and grows wild in all European countries; the other tender. See each below, under its proper head.

Hardy kind and Varieties.

Consists of one species, *Common Gorse or Whins*, having several varieties, all shrubby, very thorny plants, natives of England, &c.

¹ *ULEX Europæus*.

Common European Ulex, commonly called Furze, Gorse, or Whins.] Rises with upright, hard, woody, whitish-brown stalks, branching numerously and bushy, five or six feet high or more, having green shoots and

branches, all very closely armed with strong green spines sparsedly; small, acute, hairy leaves; and numerous large yellow flowers all along the sides of the young branches.

Varieties are.] Common yellow Furze of our wastes and heaths.—White flowered Furze.—Long-spined Furze.—Short-spined Furze.—Large French Furze.—Dwarf Furze.—Round podded Furze.

They all flower in March, April, and May, very profusely, succeeded by turgid pods, containing the seeds; ripening in autumn.

This species and varieties are remarkable for having all their young branches, shoots, and spines of a lasting green colour, but are deciduous in leaf, which come out in the spring and soon fall off, though from the nature of their numerous branches and spines remaining always green, they appear like evergreens, and we have ranked them accordingly in that tribe. See EVERGREENS.

It grows wild on wastes, heaths, and commons in England and all other countries in Europe, often overspreading large tracts of ground, so is not generally cultivated in gardens, except sometimes a few in extensive shrubberies for variety and observation, and for which purpose a few plants of the different sorts merit admittance in large grounds, both as flowering shrubs and evergreens, as they will effect a singular diversity at all seasons.

The Common Furze is likewise sometimes cultivated for outward hedges to fields, generally sowing the seed on the top of dry banks in drills an each deep, where the plants are always to stand, suffering them to grow up thick quite from the bottom; and will form a close regular hedge, by clipping with garden-shears every summer, in moist weather; though as this kind of hedge, when old, is apt to die off in gaps, become straggling, and naked and hollow at bottom, it is but in small estimation; however, those who

U L E

who incline it may easily raise a hedge, by sowing the seed in autumn or spring in any light soil, in drills as above in the place where the hedge is intended.

Tender Kind.

* *ULEX Capensis.*

Ulex from the Cape of Good Hope, or African Berry-bearing Furze.] Rises with a hard ligneous stem, branching four or five feet high, having flexible green branches, terminated each with a single spine; small, obtuse leaves singly, and numerous flowers along the sides of the branches.

The flowers of both these species of *Ulex*, and respective varieties, are all of the papilionaceous or butterfly kind, and composed each of five petals, see the *Characters*; and in the Common Furze particularly, the flowers rise very numerous all over the plants, appearing very conspicuous; succeeded by great abundance of seed, which is discharged from the pods widely around, and fill the ground with many young plants.

If intended to cultivate the Common European Furze and varieties, it may be introduced sparingly in any of the large shrubbery quarters, as before hinted; either raise them from seed, or procure young plants.

And the second sort must be potted, and placed among the green-house plants to have shelter in winter.

They are all propagated by seed.

Sow that of the first sort either in autumn or spring in any light ground, either in patches in the shrubbery, where it is designed the plants are to remain, or in drills in nursery beds, and transplant the plants while they are quite young, for as they have hard, woody, naked roots, they do not succeed well by transplantation when grown large.

But when intended to raise a Furze hedge, always sow the seed at once in the place where you design the hedge to be, in drills an inch deep, suffering the plants to remain in the same place, being careful to keep them clear from weeds the first two or three years till they are a little advanced in growth.

The second species may also be raised from seed, which must be obtained from Africa, its native soil; sowing it in pots and plunge them in a hot-bed, and when

U L M

the plants are come up, two or three inches high, prick them in separate small pots, and manage them as other green-house shrubs.

The propagation of this sort may also be tried by layers and cuttings, assisted also by plunging the pots of cuttings in a hot-bed or bark-bed.

ULMUS.

Elm Tree.

The Elm is a most valuable deciduous timber-tree, of lofty and magnificent growth, and of great estimation both as an eminent forest tree, and for various garden plantations, hereafter hinted; arises to a very considerable stature and magnitude, with a large, regular, branchy head, closely adorned with oblong, oval, rough, dark-green leaves, and bunches of small apetalous flowers of no beauty, succeeded by small roundish seeds.

Class and order, *Pentandria Digynia.*

Characters.] CALIX, is monophyllous, five-parted at the rim, coloured within, and permanent. — COROLLA, no petals. — STAMINA, five awl-shaped filaments, twice the length of the calix, having short, erect, four-furrowed antheræ. — PISTILLUM, an orbicular erect germen, two reflexed styles, terminated by downy stigmas. — PERICARPUM, a large, oval, compressed, membranous, drupaceous fruit, including one roundish compressed seed.

There are only three species of *Ulmus*, all of the tree kind and deciduous tribe, and all proper for any hardy plantation; though there is only one species common in England, which, however, comprehends many excellent varieties, consisting of the various sorts of Elms that exhibit themselves in field hedge-rows, woods, and garden plantations in almost all parts of the kingdom.

* *ULMUS Campestris.*

Field or Common Elm Tree.] Rises with an upright, straight stem, and regular branchy head, sixty or seventy feet high or more, covered with a rough bark; largish, oblong, oval, doubly-ferrated, rough, dark-green leaves, unequal at the base; and reddish or green flowers in bunches towards the ends of the branches; succeeded by oval fruit, furnishing ripe seeds the end of May or beginning or middle of June.

Varieties.] Common small-leaved English Elm.

Elm.—Larger rough-leaved English Elm.—Small-leaved Cornish Elm.—Narrow-leaved Wych or Scotch Elm.—Broad-leaved Wych Elm.—Rough-barked Dutch Elm, with large leaves.—Yellow or gold striped-leaved Elm.—Silver striped Elm.—Silver-dusted Elm. All of which are varieties of the same species, having all doubly-ferrated leaves, unequal at the base.

Their principal variation and difference of growth is as below.

Small-leaved English Elm.] Is of fine, straight, lofty growth, branching very numerously, regular, and erectly in a beautiful picturesque manner, very closely garnished with smallish oval leaves, and attains a great magnitude.

It is found growing abundantly in the hedge-rows of fields in the south of England, and the counties round London, &c. and on account of its lofty stature and close, regular, branchy head, is an approved sort for all garden ornamental plantations, as being the most estimable for beauty and elegance of growth, of all the varieties of Elm; also as a forest or timber-tree next in size and value to the oak for strength and durability.

The large-leaved English Elm is distinguished from the former by its leaves being broader and rougher.

Narrow-leaved Cornish Elm.] Is also of straight handsome growth, almost next in stature to the English Elm, branching erect very close and regular, and very closely garnished with small, oval, lively green leaves.

Is highly valued both for ornamental plantations, and as a forest-tree.

Wych or Scotch Elm.] Rises to a great height and magnitude of trunk, with a large, spreading, branchy head, having very large, oblongish, rough leaves.

Both the varieties of this *Narrow and Broad-leaved Wych Elm*, are alike in their general growth, having much more spreading branches than the two former sorts; are remarkably swift growers, and will prosper in almost any soil, and soon attain a stately growth, so are proper to plant as forest-trees and for ornament in parks and other capacious places, and in avenues, &c.

Dutch or Rough-barked Elm.] Grows very large, branching irregularly, and widely around, covered with a rough fungous bark; produces large, vigorous shoots distantly placed; and large, oval, acute-pointed,

very rough leaves. Was first introduced from Holland many years since, and was formerly in much esteem for forming ornamental hedges in gardens, and other trained devices; but by its strong, irregular, open growth, is improper for such purposes, and is much better calculated for planting in parks, fields, avenues, &c. and suffered to grow rural; also to plant as a timber-tree.

All the varieties of Elm arrive to very large timber-trees, as may be observed by old trees growing in parks, hedge-rows, and avenues, and the timber is exceedingly valuable for many strong purposes, such as most kinds of wheel-wrights work, water-pipes for conducting water under ground, for water-pumps, and various other uses in different trades, where strength and durability is required; and, therefore, as they are also of a free, expeditious growth, and will thrive in any common soil, and exposure; they demand universal culture as forest-trees, both in assembly with other trees of the forest kind, and to form woods, thickets, and ranges by themselves; and to plant in hedge-rows along the borders of fields, and in clumps in the corners thereof; observing the English Elm, Cornish, and Wych Elms, are the most eligible sorts for general culture as timber-trees; though it is adviseable to plant some of all the varieties to effect the greater diversity in the plantations; and all of which are easily raised, some from seeds, and all of them also, both by layers, suckers, and by grafting, as hereafter directed, or may be purchased very reasonable at all the public nursery grounds.

Remarking they should generally be planted out finally while they are young, i. e. from four or five to six or eight feet high, as at that size they will generally take root, establish themselves, and grow more freely and expeditiously than older trees. See PLANTATION.

Though it is observable of the Elm, in particular, that they will bear removal when large, better than almost any other tree, on account of the root being furnished with numerous smaller roots and fibres, spreading horizontally near the surface, so as trees of fifteen or twenty feet high or more, may be safely removed, as they will often readily rise with a large spread of roots, and frequently with balls of earth thereto; and being

being planted in a capacious pit, will readily strike, and grow freely.

However this removal, or transplantation of large Elms, is not an eligible practice for those intended for timber-trees, but only occasionally in garden-plantations, in places where an immediate shade or shelter is wanted, or to form a blind where necessary, or to hide any disagreeable object; for all of which purposes large Elms may be more readily removed with success than any other tree of the deciduous tribe.

But Elms, considered for purposes in garden-plantations, they are employed occasionally for ornament, and for shade and shelter; both as rural objects, and for training uniformly. Considered, however, as rural trees, they are excellently adapted for forming avenues, either alone, or in concert with other deciduous trees of lofty stature, and to assist in forming boundary plantations of capacious lawns in parks, &c. likewise to form shade, by being disposed either in thickets or clumps, or ranged along near the verge of shady walks, &c. and are likewise excellent to plant for shelter, where necessary, being planted in groves, thickets, clumps, or single ranges, at a little distance, they will break the violence of tempestuous winds and cold blasts, both from the main habitation, and from particular districts of the garden; and have a fine ornamental effect, disposed in extensive open places, some in strait ranges, others in clumps, and some as single detached standards; in all of which modes of planting them, they should generally be suffered to assume their own natural growth, except trimming off large lateral shoots from the stem, and reducing very irregular straggling branches of the head.

For training uniformly, no deciduous tree is better adapted; they form beautiful lofty hedges, very close from bottom to top, from ten to forty or fifty feet high; the English and Cornish elms particularly, and which two varieties were formerly in great repute in forming lofty, towering hedge-work in gardens, both internally, and on the outer boundary, along road sides, serving both for ornament and shelter. And Elm hedge-work was also often trained into arches, porticoes, pilasters, galleries, &c. so as to produce a very noble effect: and for all which purposes of uniform training, the small-leaved English and Cornish Elms, above noticed,

are considerably the best calculated, no account of their thick and regularly-branching growth, and close-placed foliage. See HEDGES.

All the sorts of Elm will grow well enough in any common soil, but succeed best in a rich, deep earth, or that of a loamy nature; though we may often see large and prosperous Elms on all sorts of land, both rich and poor, moist and dry; generally, however, allowing the English Elms the best situations; and the Wych and Dutch Elms may be planted occasionally on the coarsest soils.

The season for removing or transplanting Elms, may be almost any time in open weather, from the first fall of the leaf in October or November, till March. See PLANTING.

Method of Propagation, &c.

The propagation of Elms is effected different ways; as by seed, suckers, layers, and occasionally by grafting.

By Seed.—The raising of Elms from seed, is more particularly practised for the Wych Elm, which ripens seeds abundantly every summer in May or June; the others do not always perfect seed in this country; therefore about the end of May, or beginning of June, when the Wych Elm-seed is perfectly ripe, let a due quantity be procured for sowing. Then may proceed to sow some of it almost directly, in four-feet-wide beds, half an inch deep, (see SOWING SEED); and the rest may be kept till spring, to insure the greater chance of success; previously drying it well, out of the sun, then put it up close, till towards autumn, when it will be proper to mix it with sand, to preserve it more effectually through the winter, till the middle of February; then sow it in beds, as above; remarking of that which was sowed in summer, or as soon as gathered, it will be of advantage to hoop the beds over with rods, in order to be covered with mats occasionally, to afford shade from the hot mid-day sun, giving also occasionally waterings in dry weather; and thus in a month many of the plants will come up, being careful to keep them well weeded, as they may require, and a repetition of moderate waterings, continued in dry weather: though the whole will not probably come up before the following spring; but those of the spring sowing generally all come up regularly together the same season, in April,

April, and often assume a freer growth than those which came up in autumn; however, in both cases suffer the seedling plants to have one or two years growth in the seed-bed, then plant them out in nursery lines, the rows three feet asunder, and the plants fifteen or eighteen inches distant in each row; here give them the common nursery care, and train them for the purposes intended. If for standards, either for timber, or ornamental plantations, train each to a single stem, and as they advance in height, clear the stem from all strong lateral shoots, leaving only the very small twigs, just to draw and detain the sap, for the better augmentation of the stem; suffering the leading top-shoot to remain entire, as also the principal branches of the head.— And those designed for hedge-work, &c. let them branch out all the way, and become feathered or branchy to the bottom, or as low as may be required for the trained purposes intended, only trimming them occasionally, either with the knife or garden-shears, as you shall see proper, to give them the intended form.

And thus all the sorts being trained in the nursery for the purposes intended, till they have four or five years growth, they will be fit for final transplantation, where they are to remain.

By Suckers.—Most of the sorts of Elms send up many suckers from the roots, but most plentifully in the English and Dutch sorts; and which, if taken up carefully with the roots, they will form good plants; therefore in autumn, winter, or spring, having recourse to any large trees that send up plenty of suckers, let these be dugged up, with as many fibres as possible; and of which chusing only such that are well rooted, trim them for planting, by cutting them down at top to six or eight inches; lay them in small trenches or drills, five or six inches deep, one row in each, half a foot apart, and the drills about half a yard asunder; giving waterings in spring and summer; and here let them remain two years, to form good roots, then transplanted in wide nursery rows, and managed as directed for the seedlings.

By Layers.—All the sorts of Elms may be easily raised by layers, previously preparing a quantity of stools, to produce shoots, situated near the ground, for laying (see

STOOLS.) And the proper season for laying them is autumn or winter, performing it by slit-laying, (see LAYERS); and as soon as all are layed, and moulded in, top every layer with a knife, down to one eye above ground, and the work is finished.

Thus those layers will readily take root in spring and summer following, and shoot at top probably two or three feet long by the next autumn, when they should be detached from the stools, and planted in nursery rows, a yard asunder, and half a yard distant in the rows; and when they begin to shoot, train them with one leading shoot only, as observed for the seedling Elms, managing them in the same manner.

By Grafting.—All the varieties of elms may be propagated, and continued distinct, by grafting upon stocks of the Wych Elm, raised from seed, suckers, or layers, though the seedling stocks are preferable; and this method of propagation upon the Wych Elm stocks particularly, as being the fastest and largest growers, will be found a good improvement of the other more moderate growers; such as the English Elm in particular, which being grafted on the Wych Elm, generally attains a larger growth, and sooner grows to maturity. So that having raised a quantity of seedling Wych Elms, as before directed, some rows of them may be allotted for stocks, which, after having two years growth in the nursery lines, they will be fit to graft; and the latter end of January, or beginning of February, is the proper season: at which time having procured a quantity of cuttings of young moderate shoots of the best English Elm, or any other variety you intend to propagate, and cut into four or five-inch lengths, proceed to insert them in the stocks by the method of whip-grafting. (See GRAFTING.) Observing, however, as it is most adviseable, to graft them as low as possible, the earth should be removed away a little down to each root, then cutting off the head of the stock within two or three inches of the bottom, insert the grafts one in each stock, as above, binding them close, and clay them well; then draw the earth up about, and over the clay, the more effectually to secure it from falling off by the effects of frost, &c.

Being thus grafted, the grafts will unite timeously the same spring, and shoot forth strongly in summer, half a yard, or two or three

three feet in length; observing to encourage only one leading shoot; so that if they fork at top into two or more shoots, take off the weakest, and leave the best shoot for the leader; displacing also all large side-shoots from the stem; and let the top or leading shoot remain always entire, as also the general branches of the head grow in height as fast as they can, agreeable to the nature of their growth, especially all those intended for standards.

UMBELLA. An Umbel of flowers.

It is a mode of cluster-flowering; many flowers being produced close together on so many slender foot-stalks, proceeding all from one point, or common center, and rise all to an equal height; so as the flowers they support forms generally an even round surface at top, such as in the flowers of *angelica*, carrot, parsnip, &c.

The umbellate mode of flowering differs from the *corymbus*, in which the foot-stalks also elevate the flowers to an equal height at top, resembling an Umbel. The foot-stalks of the umbellate flowers issue all from one centre or point of the common receptacle, attaining all nearly an equal length and height; whereas those of the *corymbus* rise from different points, lower and higher, and each lower foot-stalk attains a greater length than that immediately above it; so as they altogether, with the flowers at top, form also an even surface, like the umbellate flowers. See **CORYMBUS**.

In the umbellate flowers, when none of the foot-stalks of the Umbel are subdivided, it is termed a Simple Umbel; when on the other hand each flower-stalk is subdivided at its extremity into a number of smaller foot-stalks, that immediately support the flowers, so as each such foot-stalk bears at top a little Umbel, commonly called partial Umbels, and that the main or general Umbel, or aggregate, being made up of several such smaller ones, it is termed a compound Umbel.

Umbellate flowers are generally produced at the top of the stalks, and extremity of the branches of the plants of the umbelliferous tribe.

The flowers that compose an Umbel are generally numerous, and separately small, consisting each commonly of five petals, five stamens, and two styles, and each flower is succeeded by two naked seeds.

UMBELLIFEROUS plants are such as pro-

duce their flowers in an Umbel, and consist both of herbaceous vegetables and trees, but mostly of herbaceous plants.

The principal of which are, *angelica*, carrot, parsnip, parsley, celery, fennel, dill, chervil, fennel-giant, lovage, Alexanders, coriander, carraway, black master-wort, Macedonian parsley, samphire, burnet, saxifrage, &c. all of which being of the Umbelliferous tribe, mostly rise with erect, hollow stalks, generally branching in the alternate way; the leaves also are placed alternate; which in some are simple, in others fingered, and some pinnated or winged; and all the stalks and branches generally terminate in an Umbel of flowers, either simple or compound, in the different plants. See each in its proper genus.

Of this tribe of plants, several of them are valuable esculents of the kitchen-garden, and some are wholesome medicinal plants. See **KITCHEN - GARDEN** and **MEDICINAL PLANTS**.

URTICA. Nettle.

This genus consists of hardy, herbaceous plants, some of which are well known as common and troublesome weeds in gardens; and one or two species of foreign growth are retained in some gardens, to effect variety; rises with upright stalks, adorned with oblong and oval leaves, and monoecious flowers, without petals, growing in catkins at the sides, and top of the stalks.

Class and order, *Monoecia Tetrandia*.

Characters.] **CALIX**, male and female; flowers separated on the same plant, having in the males a four roundish-leaved cup; and in the females an oval cup, composed of two valves, and is permanent.—**COROLLA**, no petals, but in the males is a pitcher-shaped nectarium in the center of the flower.—**STAMINA**, four awl-shaped spreading filaments, having bilocular antheræ.—**PISTILLUM**, an oval germen, (no style) and a hairy stigma.—**PERICARPIUM**, none; a single, oval, compressed seed lodged in the permanent female calix.

There are many species of *Urtica*, and of which two of them are common in the gardens, retained as plants of variety; the other being plants of but little use or estimation, and some of them are common weeds; such as the common Stinging Nettle, which grows too fast every where, are never cultivated; the common Nettle however has great virtues

tues as a medical plant, and is also in estimation as an excellent pot-herb among poor country people, in the spring, while it is young; and is of a very wholesome, cleansing property.

The most material sorts in our gardens are the following two, both of foreign growth, but are hardy enough to succeed here in the full ground.

¹ *URTICA Cannabina.*

Hemp Urtica, commonly called Tartarian Nettle.] Hath a perennial fibrous root, sending up many square stalks, five or six feet high; having oblong, three-parted, deeply-cut leaves, placed opposite; and flowers produced in long catkins at the axillas, towards the upper part of the stalks.

It grows naturally in Tartary and Siberia.

² *URTICA Canadensis.*

Canadian Nettle.] Hath a fibrous, perennial root, sending up erect stalks, two feet high; adorned with heart-shaped, oval leaves, placed alternately; and flowers pro-

duced in branching amentums, growing erect.

³ *URTICA Cylindrica.*

Cylindrical-flowered American Nettle.] Hath a fibrated, perennial root; upright stalks, three feet high; oblong, spear-shaped, opposite leaves; and flowers produced in cylindric, undivided, solitary amentums.

All these plants are perennial in root, sending up new stalks annually in spring, flowering in July and August, and the seeds ripen in autumn.

They are all hardy plants, and succeed in any common soil.

They are retained in our gardens, to diversify the herbaceous collection, and effect variety in the pleasure-ground; and may be planted in any of the open borders, and other compartments, and in which they will endure many years, and flower annually; though their flowering is more singular than beautiful.

Propagate them by parting the roots in autumn, winter, or early in spring.

V.

VALVULA. A Valve, or opening of a seed-vessel.

A Valve is the external division or opening of a dry seed-vessel, such as a capsule or pod, which when ripe splits into two or more openings, to disseminate the seeds, and each opening or division is called a Valve.

The Valves or openings, as to number, are from one or two to five or many, in the plants of different genera; so that when a capsule, &c. is composed of one Valve, it is termed *univalve*; of two, *bivalve*; when of three, *trivalve*; four, *quadrivalve*; and of five, *quinquevalve*, &c. See **CAPSULA**.

VALERIANA. Valerian.

The plants are hardy, herbaceous perennials and annuals; some for variety in the pleasure-garden, and others for medical and esculent uses; all of the fibrous-rooted kind, sending up annual stalks, two or three feet in the perennials, the other but a few inches;

ornamented with simple and pinnated leaves in the different species; and terminated by spikes, or umbellate clusters of monopetalous, five-parted flowers.

Class and order, *Triandria, Monogynia.*

Characters.] **CALIX**, a kind of small border placed on the germen.—**COROLLA**, is monopetalous and tubulous, with the tube gibbous, and divided above into five obtuse segments.—**STAMINA**, three awl-shaped, erect filaments, having roundish antheræ.—**PISTILLUM**, a germen under the corolla, filiform style, and thick stigma.—**PERICARPIUM**, a coronated or crowned deciduous capsule, falling off before it opens, containing a single oblong seed.

There are about eighteen species; and the most material of which commonly cultivated are the following five, the first four being flowery and medical perennial plants, and the last is an esculent annual, used as a salad

lad herb, commonly called Corn-Sallad, or Lamb's Lettuce.

¹ VALERIANA Rubra.

Red Valerian.] Hath a thick, ligneous, spreading, perennial root; upright, round, smooth stalks, branching two or three feet high; adorned with spear-shaped, entire leaves; and the stalk and all the branches terminated by clusters of red flowers, having tails.

Varieties.] Deep red-flowered—Pale red-flowered—White-flowered—Narrow-leaved (*angustifolia*) with bright-red flowers,

They all flower in May or June; continuing in succession most part of summer, appearing tolerably ornamental; and ripen abundance of seed in autumn, which is often scattered by winds all around, and in crevices of old buildings, &c. and from which many young plants naturally rise, and attain maturity.

² VALERIANA Phu.

Phu, or Garden Valerian.] Hath thick, fleshy, jointed, fibrous, creeping, perennial roots; crowned with numerous leaves, mostly entire, and some divided; amidst them upright, round stalks, branching two or three feet high, garnished with pinnated leaves, and with all the stalks and branches terminated by umbel-like clusters of white flowers, having only three stamina; appearing in May and June.

³ VALERIANA Officinalis.

Wild officinal Valerian.] Hath long, fleshy, fibrous roots, collected into heads; crowned with many winged leaves; upright stalks, two feet high, garnished also with pinnated leaves, and all the stalks and branches terminated by umbel-like clusters of flowers, tinged with purple, having only three stamina; flowering in May or June.

⁴ VALERIANA Pyrenaica.

Pyrenean Mountain Valerian.] Hath fibrous perennial roots; crowned with large heart-shaped, serrated leaves, on long foot-stalks; amidst them upright, channelled stalks, a yard high, garnished with smaller heart-shaped leaves, sometimes by three together, near the top, and the main stalk and branches crowned with umbel-like bunches of pale-red flowers, having three stamina; flowering in June.

⁵ VALERIANA Locusta (annual).

Locusta, or Lamb's Lettuce, commonly called

Corn-Sallad.] Hath fibrous annual roots; crowned with small, oblong, narrow leaves, broadest and rounded at the top; and when it shoots for seed, rises with a forking, slender stalk, only a few inches high, garnished with small leaves, and terminated by clusters of small white flowers, having only three stamina.

This grows naturally in corn-fields in England, &c. hence is commonly called Corn-Sallad, as being used as a sallad herb; and as such it is also cultivated in gardens for winter and spring use.

Varieties.] There are many varieties of this, differing in the form and size of the leaves; some being very narrow, others broader and obtuse, or oblong and spear-shaped; some being entire, and some are serrated or indented, &c. but possess all the same virtues, and may be indifferently used as sallad herbs, to use while young, before they grow large and rank tasted; and they prove substitutes in winter and spring sallads, when the garden-lettuce is scarce.

All these five species are very hardy plants, and prosper in any common soil of a garden, in all seasons of the year.

The first four are perennials, durable in root, and annual in stalk, which rise from the root every spring, flower in May or June, ripen seed abundantly in August, then decay down to the ground.

All these four perennial sorts may be employed in the pleasure-ground, for ornament and variety; and the second and third sort also as medical plants, and as such are highly valued: may be all had at the public nurseries in the proper planting season, autumn, winter, or spring; and may all be planted in any of the open compartments, in assemblage with other large herbaceous perennials; where they will endure for years by the root, and flower annually in their proper season, and multiply abundantly by the root; and may also be raised from seed. See their *Propagation*.

However, the second and third sorts, *Valeriana Phu* and *Valeriana Officinalis* being also very valuable medical plants, if intending to cultivate them as such, they should be disposed in beds among other medicinal herbs.

But as to the fifth sort, *Valeriana Locusta*, an annual, it is calculated only as an escul-

lent herb in fallads, principally in winter and early spring; being sowed in autumn towards the latter end of August, and in September, in any open situation, and raked in, they will come up the same year, thinning the plants to three or four inches, and they will be fit for use in winter and spring following: some may also be sowed early in the spring, to continue a longer succession.

VARIETAS.

A Variety.

Varieties are the off-spring of certain species, varying in some accidental habit of growth from the natural species or parent plant; yet their variation being generally confined to some particular parts, they still retain the specific mark of distinction of the parent, to distinguish them from plants of a different species.

So that a species often comprise from one or two, to some hundreds of Varieties, varying in some particular, either in their habit of growth, foliage, flowers, fruit, æconomical qualities, &c. and both trees and herbs, annuals, biennials, and perennials are subject to variation.

For example, species are subject to numerous accidental modes of variation, effected either by the difference of culture, climate, soil, age, &c. and consist often in the difference of magnitude; luxuriant, and dwarf growths; erect, and trailing plants; smooth and prickly Varieties; broad and narrow-leaved kinds; entire-leaved, divided-leaved, and curled-leaved; spotted, and variegated-leaved; smooth-leaved, hairy-leaved, and downy-leaved plants; single-flowered, double-flowered, and proliferous flowered; white, red, blue, yellow, and variegated-flowered; sweet-scented, rank-scented, &c. Likewise the fruit in some species are liable to great variations; as round fruit, oval fruit, oblong fruit; also smooth fruit, furrowed fruit, warted fruit, hairy and downy fruit; likewise fruit varying greatly in size, in the same species; likewise in colour, taste, and quality: in some species also, the root is found to vary, as in the carrot, radish, turnep, and potatoe, which often assume different forms and colours; and some species furnish both male and female Varieties in different plants, as in the dioecious class; thus the above, and numerous other circumstances occur in the various forms of sport-

ing nature, in exhibiting so many different Varieties in certain species.

But notwithstanding all the above different modes of variation in the particular parts of the varying plants of a species, if those of each species still all retain the same specific botanic mark of distinction, as that which distinguishes the respective natural species from all others, it proves them all Varieties or off-spring of the same parent species.

For as every different species in a genus is distinguished by some particular uniformly constant mark in some part of its growth, all plants in the same genus bearing exactly the same specific mark of distinction unchangeably, are, notwithstanding their accidental variation in other parts of their growth, all Varieties of one species.

Therefore, all the plants that are produced from the seed of the same species, although they may assume different forms and appearances, are to be regarded as the genuine Varieties.

The difference betwixt a species and a Variety is, that a true species raised from seed, will, notwithstanding it may sport into different variations, it still retains its true and constant specific mark through all its Varieties; and suppose there are Varieties of that species with broad leaves, and narrow leaves, white flowers, red flowers, and blue flowers, &c. and that if you sow the seed of any one, it will probably produce seedling plants of all these sorts.

It is principally from seedling plants that the different Varieties of particular species first obtain, exemplified in the *auricula*, *polyanthus*, &c. each being a distinct species of the same genus; and each consists of innumerable Varieties, in the colours and variegations of the flowers, all first obtained from seed; which from that of the same plant, often sport into many different colours and variegations in the flower; each variation forming a genuine variety; and probably not one of them with a flower exactly like that of the original parent plant: yet each Variety retains the specific difference of its respective species, the *auricula* never changing to the *polyanthus*, nor that to the *auricula*, but the varieties of each keep their proper distinction; for the *auricula* in all its Varieties, continues its *smooth*, *fleshy*,

fleshy, serrated leaves; and the polyanthus, its *rough dentated leaves*. The same is also observable of the carnation, ranunculus, anemone, tulip, and numerous other plants, which sport wonderfully in Varieties.

Likewise numerous sorts of trees, of the fruit kind particularly, are remarkably sportive in Varieties; both in their modes of growth, foliage, and fruit: for example, the botanists admit of only one species of apple-tree, which however furnishes an almost endless Variety of its fruit, in regard to shape, size, colour, taste, and quality; as also in the growth of the trees, differing both in magnitude and size, as well as in the size and colour of the foliage; and its specific distinction is, *serrated leaves, and close sitting flowers growing in an umbel*, which distinction runs through all the numerous Varieties, however different the trees may be in magnitude of growth, leaves, and fruit: the same is also observable of the pear, plum, common-cherry, peach, &c. there being only one species of each of these, but the Varieties of the fruit are very numerous; all of which different variations of the above sorts of trees were first obtained from seedlings; i. e. trees raised from the kernels or stones of the fruit; and almost all the fruit-tree kind sport exceedingly in their seedling plants; insomuch, that out of hundreds of trees raised from the seeds of the best fruits, very few, if any, will produce fruit exactly like the parent, or that possess any good perfection; so that on account of the uncertainty of continuing the approved sorts of fruits from seedling plants, recourse is always had to grafting and budding to propagate the sorts intended, or to continue and encrease any new-acquired good Variety.

The greater number of varieties, both of herbaceous plants and trees, are of a variable or sporting nature; so as when raised from seed there is no dependence on having the seedlings come the same sort again, but vary into different sorts of one another; in which case, the propagation of those that are perennial, to continue them with certainty, is effected either by suckers, off-sets, or slips of the root; or, in the woody kinds, by layers, cuttings, grafting, and budding: but as to annuals, there is no other resource

for propagating them than by seed, except in some few sorts by cuttings, such as the *Chrysanthemum* and *Nasturtium*, &c. but in many sorts where particular attention is observed in saving the seeds, always only from the most perfect kinds, they will continue tolerably permanent, and often come the same again, or but with very little variation.

Many of the kitchen-garden plants and annual flowers, consist of many Varieties in the same species; yet by good care in always saving seed from the most perfect plants that discover no signs of a degeneracy, they remain permanent from seed year after year.

However, most of the perennial tribe, both herbaceous and woody kinds, as they being generally more variable from seed, they afford abundant opportunities to continue the permanency of any particular Variety, by off-sets from the root, suckers, layers, cuttings, grafting, and budding, as before noticed.

Sometimes, however, plants though not raised immediately from seed, will from some accidental cause vary considerably from their natural growth, and assume a very different appearance; originating either through culture, climate, exposure, soil, age, diseases, luxuriancy or poverty of nourishment, contusions, or other circumstances; and hereby produce accidental Varieties in some particular parts of growth.

As to the determining the reality of the Varieties, it is in many sorts most easily accomplished by comparing the variable plant with the specific description of the natural species, and the variations of growth of the variety with the same parts in the natural plant; though there are many varieties that require both knowledge and experience of the most expert botanist to distinguish them with certainty.

From not observing the true specific distinction, Varieties have been ranged as distinct species, and thereby exceedingly encreased the number of species erroneously, and caused great confusion in the true botanic arrangement; for on account of the slightest difference new species were introduced, which modern improvers of botany discovered to be only Varieties of certain species.

species, and have corrected the errors accordingly.

Therefore, in botanic arrangements, we ought to be careful not to substitute a Variety in the room of a species, which being sometimes a difficult point, requires the greatest care; and the cause of our running into so many errors in this particular, is owing to nature's working and appearing in so many different forms, either through the nature of different countries, climates, soils, exposures, and culture, &c. as before observed.

We have, however, in the course of the arrangement of the numerous articles in this book, been careful to collect the different Varieties under their respective species, exhibiting at once each species and its Varieties, when any, arranged distinctly together under their proper genera.

VERATRUM. White Hellebore.

This genus is composed of hardy herbaceous perennials for ornament and variety in the pleasure-ground, and for medicinal use; are of the fibrous and tuberous-rooted tribe, rising with upright annual stalks, some a yard or more high, others hardly a foot; garnished with large, oblong, and spear-shaped, nervous leaves; and all the stalks and branches terminated by spikes of closely-placed hexapetalous flowers.

Class and order, *Polygamia Monoecia*.

Characters.] CALIX, hermaphrodite and male flowers on the same plant, all without any calix.—COROLLA, six oblong, spear-shaped, serrated, permanent petals.—STAMINA, six awl-shaped filaments, having quadrangular antheræ.—PISTILLUM, three oblong, erect germens, terminating in a very short style; which in the males is scarce visible, and simple stigmas.—PERICARPIUM, three oblong, erect, compressed, univalvular, unilocular capsules, opening on the inside; containing many oblong, compressed, membranaceous seeds.

There are only three species, all very hardy perennials; the two first of which are tall growing plants, with large broad leaves; and the third is of much lower growth and narrower leaves, as in their descriptions below.

¹VERATRUM Album.

White-spiked Russian Veratrum, or Common White Hellebore.] Hath a thick, fibrated, peren-

cial root, crowned with large, oblong, oval, nervose leaves, near a foot long, and half as broad; upright, round, thick, very branchy stalks, three or four feet high; garnished with leaves diminishing gradually upward; and all the stems and branches terminated by decompound or subdivided spikes of whitish-green, closely-placed flowers, having erect petals; appearing in May and June.

It inhabits the mountains of Russia, Siberia, and Austria, &c. but hath been introduced into the English gardens, both as an ornamental and medical plant.

²VERATRUM Nigrum.

Black-spiked Hungarian Veratrum.] Hath a thick, fibrous, perennial root; crowned with large, long, nervous, yellowish-green leaves; upright, thick stalks, branching four or five feet high, garnished with a few leaves; and with all the branches terminated by compound, less-divided spikes of dark-red flowers, having spreading petals; appearing in June and July.

It grows naturally in Hungary and Siberia.

³VERATRUM Luteum.

Yellow-spiked Virginia Veratrum.] Hath a bulb-like tuberous root, sending up oblong, spear-shaped, nervose leaves, spreading close to the ground; an upright single stalk, about ten inches or a foot high; garnished with a few close-fitting leaves, and terminated by a close, single spike of yellow flowers; in June and July.

All these three species are hardy herbaceous plants, durable in root, but annual in leaf and stalk, which rise in spring; the leaves rising large, broad, and folded, assume a singular appearance; and between them the flower-stalks of thick, robust growth, rising to a flowering state in May, June, and July; having all the branches terminated by the spikes of flowers, which singly are rather small; but are collected numerous and close in each spike; succeeded by ripe seeds in autumn, in the first and second sort particularly; and soon after the seeds are ripe, the stalks decay.

These plants have been long inhabitants of the British gardens, for variety and medical purposes; particularly the first and second sorts.

They all succeed in any common soil and exposure.

As

As to their general merit as ornamental plants, or for variety, &c. they having great singularity in their large furrowed leaves, as well as in their different modes of flowering; they demand culture in every herbaceous collection, disposed in the open borders and other compartments of the pleasure-ground; in which they will effect a most agreeable diversity, in spring and summer.

Likewise, as medical plants, the first sort in particular (*Veratrum Alba*) is in great repute: the root of which forms a powerful sternutatory powder; and for which purpose, the plants may be planted in any bed or border of common earth.

The propagation of all the three species is by seed, and by parting the roots.

By Seed.—This may be sowed either in autumn, soon after it is ripe, or in spring, in a bed of light earth, and raked in; and they will come up in April or May, giving occasional watering and weeding; and in July or August, prick them out in nursery-rows, to remain a year or two to grow strong; then transplanted where they are to remain.

By parting the Roots.—Autumn, when the leaves decay, or early in spring, before new ones shoot forth, is the proper period; when the roots may be divided into several slips, not too small, and planted at once where they are always to stand.

VERBASCUM.

Mullein.

The plants are hardy, herbaceous, perennials, biennials, and annuals, proper to diversify the borders and other compartments of the pleasure-ground as flowery plants; also for medicinal preparations; all of the fibrous-rooted tribe, sending up erect stalks, mostly tall; from two or three, to four or five feet stature; and some of much lower growth, garnished in the different sorts with oblong, and oval leaves; and monopetalous, rotaceous flowers in spikes, and singly at the sides, and ends of the branches.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, is small, monopetalous, acutely five-parted, and permanent.—COROLLA, is monopetalous, wheel shaped, with a very short cylindric tube, and spreading brim cut into five oval segments.—STAMINA, five awl-shaped, declinated,

shortish filaments; having roundish, compressed, erect antheræ.—PISTILLUM, a roundish, germen, filiforme, inclining style; and a thickish, obtuse stigma.—PERICARPium, a roundish, bilocular capsule opening at top, and numerous angular seeds.

There are about eleven species of *Verbascum*, some perennial, others biennial and annual, as before noticed; and the most material sorts thereof are the following; though the first three or four sorts are the most common in the English gardens.

¹VERBASCUM *Ferrugineum*. (Perennial.)

Ferrugineous, or Iron-coloured Moth Mullein] Hath a perennial root; oval, oblong, slightly-crenated leaves; upright stalks, three or four feet high, terminating above in long loose spikes of yellowish iron-coloured flowers.

²VERBASCUM *Nigrum*. (Perennial.)

Black Mullein with a yellowish-purple flower.] Hath a perennial root; oblong, heart-shaped, foot-stalked leaves, eight or ten inches long, hoary underneath; upright, angular stalks, four or five feet high, garnished with a few narrow leaves, and terminated by long spikes of yellow flowers with purple antheræ.

It grows by way sides, &c. in England, and most parts of Europe.

³VERBASCUM *Phæniceum*. (Perennial.)

Phœnician Purple Moth Mullein] Hath a perennial, and sometimes a biennial root; sending up oval, crenated, rough-spreading leaves; an upright stalk about three feet high, almost naked of leaves; and purplish flowers along the side of the stalk and branches.

⁴VERBASCUM *Myconi*. (Perennial.)

Verbascum Myconi, or Borage-leaved Mullein] Hath a perennial root; crowned with oval, thick, woolly leaves spreading flat on the ground; slender, naked foot-stalks four or five feet high, divided upward into smaller, each terminated by one large blue flower. Is a native of the Pyrenees.

⁵VERBASCUM *Thapsus*. (Biennial.)

Thapsus or Great White Mullein.] Hath a biennial root; long, broad, whitish leaves, woolly on both sides; an upright, thick, firm stalk, five or six feet high, garnished with decurrent, woolly leaves, and terminating above in a long thick spike of yellow flowers.

It.

It grows naturally in England, &c. by way-fides, and other uncultivated sterile places; but sometimes retained in gardens for variety, and as a medicinal plant.

⁶ *VERBASCUM Sinuatum.* (*Biennial.*)

Sinuated Mullein.] Hath a biennial root; oblong, sinuated, pinnated leaves; an upright, firm stem, four or five feet high, having the primary or first branches opposite, and garnished with oblong, amplexicaule, naked leaves; and clusters of yellow flowers along the sides of the branches. Grows naturally in France and Italy.

⁷ *VERBASCUM Phlomoides.* (*Biennial.*)

Phlomoide Mullein with a large Yellow Flower.] Hath a biennial root; oval leaves, woolly on both sides; an upright, purplish stalk, four or five feet high; garnished with small, oval, hoary leaves, the lower ones having foot-stalks; and the stalks terminating in thick spikes of large, yellow flowers. Grows naturally in Italy.

⁸ *VERBASCUM Lychnitis.* (*Biennial.*)

Hoary white Mullein.] Hath a biennial root, large, oblong, wedge-shaped, woolly leaves; an upright stalk, three or four feet high, garnished with white leaves, and small white flowers in spikes at the joints and ends of the stalk and branches. Grows in England, &c. in sandy, chalky situations.

Variety.] With yellow flowers.

⁹ *VERBASCUM Blattaria.* (*Annual*)

Blattaria, or Amplexicaule-leaved Moth Mullein.] Hath an annual root, upright stalk four or five feet high; oblong, smooth, sinuated, complexicaulous leaves; and yellow flowers singly along the sides of the stalk and branches.—Grows naturally in England, &c.

Variety.] With white flowers.

All these nine species of the *Verbascum*, are of the herbaceous tribe; the first four are perennials with durable roots, the next four biennials, and the last of all is an annual; all of which rise with erect stalks in the spring, attaining to full height, and flower in June and July: in all of which the flowers are monopetalous and five-parted; and produced in spikes and other modes of flowering, as in their respective descriptions; are mostly of an odoriferous nature, and are

succeeded in most of the sorts, by ripe seeds in August or September.

They are all very hardy plants, that will prosper in any common soil and exposure in the common borders, &c. of a garden.

Considered as garden plants, they merit admittance, to diversify the large borders and other similar compartments of the pleasure-ground; particularly the larger sorts, which though not so ornamental as some, yet by their different foliage, luxuriant stems, and different colours and modes of flowering, they will effect a conspicuous variety.

Method of Propagation.

They are propagated by seed and off-sets of the roots.

By Seed.—Sow it either early in autumn or spring, in a bed or border of light earth, and raked in: and when the plants are come up three inches high, plant them out either in the borders to remain, or in nursery-lines till autumn, then transplanted finally; though the annual sort should be planted out early in summer to remain, or sowed at once in patches where the plants are intended to stand.

By Off-sets.—All the perennial sorts furnish off-sets from the sides of the roots, which may be detached in autumn, or early in the spring, and planted either where they are to remain to flower, or in nursery-rows till autumn, then removed to their borders, &c.

VERONICA.

Speedwell.

This genus consists of many herbaceous perennials, &c. some of them retained in gardens for variety; rising, some with trailing, and others with erect stalks, from five or six inches, to so many feet high; adorned mostly with smallish, oval, oblong, and spear-shaped leaves, and of other different forms in the several species; and monopetalous, wheel-shaped, four-parted flowers, in spikes and bunches at the sides and ends of the branches.

Class and order, *Diandria Monogynia.*

Characters.] CALIX, is divided into four spear-shaped segments, and permanent.—COROLLA, is monopetalous, wheel-shaped, and divided above into four oval segments.—STAMINA, two rising filaments, with oblong

V E R

oblong antheræ.—PISTILLUM, a compressed germen, slender declining stile, and simple stigma.—PERICARPIUM, a heart shaped, compressed, quadrivalve, bilocular capsule, having many roundish seeds.

There are upwards of thirty species of *Veronica*, mostly herbaceous perennials and annuals; a few of the former are the most remarkable, some as medical plants, and for variety; others as flowery ornamental plants to decorate the compartments of the pleasure-ground, and are mostly all of the fibrous-rooted tribe; some natives of England, and some are exotics from different distant parts of Europe and America; and are of hardy growth.

¹ *VERONICA Officinalis.*

Common Officinal Speedwell of the Shops.] Grows with low procumbent stalks, rooting at the joints; oval, serrated leaves, placed opposite; and the stalks terminated by spikes of small blue flowers.

It is a native of woods, commons, and sterile pastures in England, &c. and is a valuable medicinal plant.

² *VERONICA Serpyllifolius.*

Mother-of-Thyme-leaved Speedwell, or Paul's Betony.] Hath trailing stalks, branching and rooting at the joints; small, oval, smooth, crenated leaves; and white flowers in racemous spikes terminating the branches.

It inhabits moist meadows in England, &c. and is sometimes used in medicine.

³ *VERONICA Hybrida.*

Hybridaceous Speedwell, or Welsh Veronica.] Rises with an erect, branchy stalk, eight or ten inches high; oblong, obtuse, serrated, rough leaves, placed opposite; and the stalks and branches terminated by long spikes of blue flowers. Grows on the mountains in Wales, &c.

⁴ *VERONICA Siberia.*

Siberian Septifolious Veronica.] Rises with upright, firm, hairy stems, four or five feet high; broad, oval, spear-shaped leaves, by sevens, surrounding the stalk in a verticillus; and the stalks terminated at top by long spikes of blue flowers.

⁵ *VERONICA Virginica.*

Virginian Quaternate-leaved Veronica.] Rises with upright stalks, four or five feet high; garnished with spear-shaped, quaternate, and quinate leaves; and terminated by long spikes of white flowers.

⁶ *VERONICA Austriaca.*

V E R

Austrian Blue Veronica.] Rises with upright, branchy stalks, three feet high; linear-spear shaped leaves, cut pinnately; and spikes of blue flowers at the sides of the stalk and branches.

⁷ *VERONICA Maritima.*

Maritime or Sea Veronica.] Rises with erect stalks two feet high; spear-shaped, unequally serrated, ternate leaves; and the stalks terminated by spikes of bright-blue flowers. Grows near the sea in several parts of Europe.

⁸ *VERONICA Incana.*

Hoary Tartarian Speedwell of Ucraina.] Rises with an erect, hoary stalk, a foot high; oblong, crenated, hoary, opposite leaves; and the stalks terminating in erect spikes of blue flowers.

⁹ *VERONICA Teucrium.*

Germander Speedwell.] Rises with erect stalks, three or four feet high; oval, obtuse, indented, rough leaves; and long spikes of blue flowers at the sides of the branches. Is a native of Germany.

¹⁰ *VERONICA Longifolia.*

Long-leaved Veronica.] Grows two feet high, with spear-shaped, acute, serrated, shining-green leaves, placed opposite; and the stalks terminated by long spikes of blue flowers. Grows naturally in Italy.

All these plants are hardy herbaceous perennials, with fibrous roots of long duration, sending up new stalks annually; arriving to full growth in May, June, and July, when they flower abundantly in spikes and clusters as in their descriptions; each spike and cluster composed of many separate flowers, universally monopetalous, wheel-shaped, and divided into four parts, and succeeded by ripe seed in August and September.

They are all hardy enough to grow any where in a garden; but are generally the most prosperous in somewhat shady moist situations.

Their merit for garden culture is principally for variety and ornament to the common borders, &c. as flowery plants; and being arranged in concert with other hardy perennials, they will effect an agreeable diversity in the summer time, when in flower.

Many of these plants are kept in the public nurseries for sale, and may be transplanted in autumn or spring in the gardens, where they will flower annually, and encrease considerably by the roots.

They

They are propagated by parting the roots, and by seed.

By parting the Roots.—This may be effected either in autumn or spring, by taking up the plant and dividing the roots into separate slips, not too small; and planted either where they are to remain, or in the nursery for a year, or till wanted.

By Seed.—Sow it in autumn or in spring in any bed or border, and raked in; and when the plants are come up and a little advanced in growth, plant them out either to remain or in the nursery.

VERTICILLUS, a Whorl.

A mode of flowering, in which the flowers are placed in whirls or rings round the joints of the stalk as in baum, sage, hyssop, &c.

VIBURNUM.

Wayfaring Tree, Gelder Rose, Laurustinus, &c.

This genus exhibits a collection of elegant deciduous and evergreen flowering shrubs, great ornaments to the shrubbery and other hardy plantations, rising with upright branchy stems, some fifteen or twenty feet high, others not half so much; adorned with heart-shaped, roundish, lobated, and oval leaves in the different species; and numerous small bell-shaped, five-parted flowers in large umbellate clusters at the termination of the branches, appearing very ornamental.

Class and order, *Pentandria Trigynia*.

Characters.] CALIX is small, five parted, and permanent.—COROLLA is small, monopetalous, bell-shaped, and divided into five obtuse reflexed segments.—STAMINA, five awl-shaped filaments, with roundish antheræ.—PISTILLUM, a roundish germen under the corolla, no style, but a turbinated gland instead of it, and three stigmas.—PERICARPIUM, a roundish unilocular berry, with one roundish hard seed.

To this genus is added the *Opulus* or *Gelder Rose*, and the *Tinus* or *Laurus Tinus*; consisting in the whole of eight or nine species, all of the hardy tree and shrub kind, six or seven of which being of the deciduous kind, and one is an evergreen.

Deciduous Kinds.

Under this head is comprised the common *Viburnum*, *Opulus* or *Marsh Elder*, and *Gelder Rose*, and four or five other species, all of the deciduous kind, or such as shed their leaves in winter; some are of English growth, others from America, and garnished mostly

with large, heart-shaped, round, and lobated leaves, and numerous small white flowers, collected in cymose umbels at the ends of the branches, as in their description.

¹ VIBURNUM *Lantana*.

Lantana, *Common Viburnum*, *Wayfaring*, or *Pliant Meally Tree*.] Rises with a woody stem, branching twenty feet high, having very pliant shoots covered with a lightish-brown bark; large heart-shaped, veined, serrated leaves, white and hoary underneath; and the branches terminated by umbels of white flowers, succeeded by bunches of red berries. Grows naturally in England in hedges, &c.

Varieties.] Striped-leaved—Oval-leaved.

² VIBURNUM *Opulus*.

Opulus or *Gelder Rose*.] Consisting of the two following varieties, one with flat-flowers, the other globular, viz.

Gelder Rose with flat Flowers, or *Marsh Elder*.] Grows eighteen or twenty feet high, branching opposite, of an irregular growth, and covered with a whitish bark; large lobated or three-lobed leaves on glandulose foot-stalks, and large flat umbels of white flowers at the ends of the branches, succeeded by red berries. Grows naturally in England in marshy places.

Common Gelder Rose, with a Globular Umbel (Roseum).] Grows fifteen or eighteen feet high, branching like the other, garnished with large lobated or three-lobed leaves, on glandular foot-stalks; and large globular umbels of white flowers at the ends of the branches, in great abundance.

Variety.] Variegated-leaved.

This tree when in bloom exhibits a singularly fine appearance, the flowers, though small, are collected numerously into large globular umbels round like a ball; hence, it is sometimes called *Snowball-tree*.

³ VIBURNUM *Prunifolium*.

Plum-leaved American Viburnum.] Grows ten or twelve feet high, covered with brown and reddish bark; roundish, crenated, serrated, smooth leaves; and the branches terminated by umbels of white flowers, succeeded by dark red berries, rarely ripening in England.

⁴ VIBURNUM *Acerifolium*.

Maple leaved Virginian Viburnum.] Grows eight or ten feet high; lobated leaves cut into three principal lobes, growing on smooth foot-stalks; and white flowers in umbels along the

the sides of the branches, rarely succeeded by berries in England.

⁴ *VIBURNUM dentatum.*

Dentated Virginia Viburnum.] Grows eight or ten feet high, having a smooth light bark; oval, dentated-serrated, plicated leaves; and large round bunches of white flowers at the ends of the branches, rarely succeeded by berries in England.

⁵ *VIBURNUM nudum.*

Naked-umbelled, or Laurustinus-leaved American Viburnum.] Grows ten or twelve feet high, very branchy on every side to the bottom, covered with a reddish or purple bark; large, oval, spear-shaped, wholly entire leaves, of a shining green colour; and the branches terminated by umbels of white flowers, resembling those of the common *Laurustinus*, not succeeded by berries in England.

Varieties.] Deciduous-leaved—Evergreen-leaved.

⁶ *VIBURNUM Cassinoides.*

Cassinoides, Bastard Cassine, or Cassinoberry Bush.] Grows eight or ten feet high, branching numerously, assuming a bushy growth; small, oval-oblong, crenated, smooth leaves placed opposite on foot-stalks, having keel-shaped glands, and small umbels of white flowers at the sides of the branches; is a native of Virginia and Carolina.

All these deciduous *Viburnums* come out into leaf in April and May, and commonly flower in June and July, the flowers small, but collected numerously into cymose umbels; are very conspicuous, succeeded by large bunches of red berries in autumn; though seldom any but those of the *Lantana* and *Opulus* attain perfection in England.

Evergreen Kinds.

Under this head is comprised only one species (*Common Laurustinus*) a well known old inhabitant of our gardens, furnishing several beautiful varieties, valuable both as fine, hardy evergreens, and elegant flowering shrubs, remarkable for exhibiting their flowers in winter and early spring in defiance of the severest cold.

⁷ *VIBURNUM Tinus.*

Common Laurustinus, or Evergreen Viburnum.] Grows eight or ten feet high or more, branching numerously from the bottom upward, assuming a close bushy growth, with the branches somewhat hairy and glan-

dulous; very closely garnished with oval, wholly entire leaves of a strong green colour, placed in pairs opposite; and whitish and red flowers, collected numerously in large umbellate clusters all over the plant, at the sides and ends of the branches, from January until March or April, exhibiting a most beautiful appearance.

Varieties.] Narrow-leaved—Broad-leaved—Shining-leaved—Hairy-leaved—White striped-leaved—Yellow striped leaved; all of which are of shrubby, bushy growth, closely garnished with leaves all the year, and produce a great profusion of umbellate flowers in winter and spring, as before mentioned.

All these different species of *Viburnum*, both deciduous and evergreen kinds, being of the tree and shrub kind, are woody and durable in root, stem, and branches; the first seven sorts are deciduous, and the eighth is an evergreen, and are all of such hardy temperature, as to grow freely in the open ground all the year, in shrubberies, and other hardy plantations; though the *Viburnum Cassinoides* is rather somewhat tender in winter, whilst young, but may be gradually hardened to bear all weathers like the other sorts, especially if planted in a sheltered situation; but as it is sometimes liable to suffer in very severe winters, it is also adviseable to keep some in pots to move under shelter occasionally in severe weather; however, all the other sorts, both deciduous and evergreen kinds, will succeed any where at all seasons without trouble.

With respect to their uses for garden-culture, they all demand attention as furniture to diversify the shrubbery, and also other ornamental plantations of the tree and shrub kind; all of which may be procured at the public nurseries, at a moderate price, and may be transplanted almost in any open weather from October till March.

In their arrangement in the shrubbery, the deciduous sorts should be disposed principally with others of that tribe, and the *Laurustinuses*, chiefly in the evergreen clumps, &c. though some distributed thinly towards the fronts of the deciduous compartments, will exhibit a lively variety in winter and spring; suffering the whole, both deciduous and evergreens to assume nearly their own natural growth, except just retrenching occasional lower stragglers from the stem, and long, irregular, rambling shoots of the head.

But the *Laurustinus* are also often employed to plant against unsightly walls, or other disagreeable fences in fore-courts, and other compartments near the main dwelling, &c. to hide their deformity from sight, by their perpetual verdure, and where they will also flower profusely, and have a very ornamental effect.

Sometimes also the *Laurustinus* is planted as detached objects in borders and capacious, spaces of grass ground, and there sometimes trained to a single stem, a foot or two high, and encouraged to branch out into a close bushy round head: in which it has a pretty effect, both as an evergreen and flowering shrub

Method of Propagation.

Many of the sorts may be propagated by seeds; all of them by layers, and many of them also by cuttings.

By Seeds.—Most of the deciduous kinds may be raised abundantly from seeds in the open ground; some of them producing plenty of berries in England, others not, and those of most of the sorts may be had of the seedsmen; all of which may be sowed in autumn or spring, in beds of common earth, and covered an inch deep; they will come up, some the first year, others not till the second; and when the plants are a year or two old, plant them out in nursery rows to remain till wanted.

By Layers.—All the sorts, both deciduous and evergreen kinds, grow freely by layers, which is the most expeditious mode of propagating them, and may be effected in autumn, winter, or spring, though the sooner the better; chusing for this purpose the young lower branches, lay them and peg them down in the earth in the common way; they will all readily emit roots in spring and summer, fit for transplanting next autumn.

By Cuttings.—Most of the deciduous kinds, particularly, grow tolerably well by cuttings; though all the sorts both deciduous and evergreen kinds may be tried by this method; it is soon done, and autumn is the proper season; chusing cuttings of the robust young shoots, cut into moderate lengths, and plant them in any moist border in rows, many of them will root and shoot at top next summer, and form tolerable little plants the same year.

VICIA.

Vetch or Tare, including also the Faba or Bean.

They are hardy herbaceous annuals and perennials, principally for economical purposes, as the common Vetch for fodder to cattle, and the seeds for poultry, &c. and the Bean, both as a fine summer esculent for the table, to eat when green and young, and when dry to feed horses and hogs, &c. though some sorts, also both of the Vetch and Bean kinds, are proper to diversify the compartments of the pleasure-ground; all of which are of the fibrous-rooted tribe, and mostly rise with annual stalks, some long and trailing as in most of the Vetch kinds; others erect, as in all the Bean tribe; garnished mostly with pinnated leaves of several pair of lobes, and papilionaceous flowers along the sides of the branches.

Class and order, *Diadelphia Decandria*.

Characters.] CALIX, is monophyllous, tubulous, and five-parted at top.—COROLLA, is papilionaceous, with an oval, broad vexillum, reflexed on the sides, two almost heart-shaped wings, and short keel, with an oblong, two-parted claw or tail.—STAMINA, ten diadelphous filaments, having roundish, four-furrowed, erect antheræ.—PISTILLUM, a long, narrow, compressed germen, filiforme style, and obtuse stigma, bearded underneath.—PERICARPIUM, a long, leathery, bivalvular pod of one cell, containing several roundish and compressed seeds.

There are about eighteen species of *Vicia*, mostly of the Vetch Tribe, and only one species of the Bean, which comprehends many varieties.

Vetch Kinds.

There are many species of the Vetch, though only a few of them have merit for general culture; some to cultivate in the fields to cut green for fodder, and to stand to ripen seed, (Tares) to feed pigeons and other poultry, hogs, &c. and some to cultivate in gardens for variety; consisting of annuals, biennials, and perennials, mostly with long, somewhat trailing, or climbing stalks, and some erect; all garnished with pinnated leaves of many pair of small lobes, terminated mostly by cirrhi or tendrils for climbing; and flowers generally from the sides of the branches, either singly or by twos, or many together on each peduncle, in

in spikes, &c. succeeded by oblong pods filled with small roundish seeds.

The most remarkable species for use or variety are,

¹ *VICIA Sativa.* (Annual.)

Common cultivated Vetch or Tare.] Rises with weak, angular, streaked, declinating stalks two or three feet long, garnished with pinnated leaves of seven or eight pair of oblong blunt lobes, and spotted stipula; and purple flowers generally two together, succeeded by erect pods in pairs, containing a few round seeds.

Varieties.] Common purple-flowered as above — White-flowered — Early summer Vetch — Black-seeded — White-seeded, &c.

This species is the sort of Vetch or Tare that is commonly cultivated in fields, to cut green for summer fodder, which is excellent feed for horses, &c. and some also to stand to bring forth seeds for the uses before hinted.

² *VICIA Biennia.* (Biennial.)

Biennial multiflorous Siberian Vetch.] Grows five or six feet long, having large pinnated leaves of ten or twelve or more spear-shaped, smooth lobes on furrowed foot-stalks, and each peduncle having many light-blue flowers, arising at the sides of the branches, succeeded by short compressed pods.

³ *VICIA Sylvatica.* (Perennial.)

Wood multiflorous Vetch.] Rises with cirrhone, climbing stalks, five or six feet long; pinnated leaves of seven or eight pair of oval lobes, and denticulated stipula, and each peduncle supporting many pale-blue flowers; grows wild in England, &c. in woods and among bushes and hedges.

⁴ *VICIA Cracca.*

Cracca or Tufted Vetch.] Rises with climbing stalks five or six feet long; pinnated leaves of ten pair of spear-shaped, hairy lobes, and entire stipula; and peduncles supporting each many blue imbricated flowers. Is a native of England and most parts of Europe.

⁵ *VICIA Cassubica.*

Cassubian Ligneous Vetch.] Hath trailing stalks two or three feet long, becoming somewhat ligneous; pinnated leaves of eight or ten pair of oval, acute, lobes, and entire stipula; and each peduncle having about six pale-blue flowers. Is a native of Germany.

The above five species are the most noted for as of the Vetch or Tare kind, some of which being in great estimation for field

culture, to produce green fodder as before noticed; but the first sort, in particular, having the most succulent stalks, are in most esteem for general culture, being generally cut whilst the stalks are green and tender, till they come into flower in June and July.

They are also sometimes introduced into gardens, as climbers, for variety, especially to diversify wood-walks, thickets, &c. to climb upon the shrubs and bushes; sowing the seed in the places where the plants are designed to remain, and they will readily come up and flower ornamentally in summer. See their *Propagation* below.

As all the sorts rise with long weak stalks, somewhat resembling the pea tribe, they either trail on the ground or climb upon any adjacent support, or upon one another, by means of their cirrhi or clasps, at the termination of the leaves; and by which they mount upon bushes or hedges, &c. several feet high, shooting up into stalk in spring, and flower in June or July; all producing papilionaceous or butterfly-shaped flowers, some but two on each peduncle, and some many as before observed, succeeded by longish pods of the leguminous kind, containing round seeds, ripening in autumn.

Method of Propagation, &c.

All the sorts are easily propagated by seeds, sowed principally where the plants are to remain in autumn or spring, both for field-culture and in gardens.

For Field Culture.—They are sowed both in autumn or spring occasionally: when intended to raise a crop to cut for early fodder, they are often sowed in autumn, about August or early in September; in order that they may come up soon after the same year, and afford an early cutting next summer; though they may also be sowed in spring both for fodder and to stand to produce seed or Tares; remarking, however, the summer Vetch in particular, being somewhat tender, should never be sowed till the spring; observing in sowing the different sorts, that the common allowance of seed is generally about two bushels to an acre, which may either be sowed broad-cast and ploughed or harrowed in, or in drills, two or three feet asunder, and earthed over an inch or two deep: that by sowing them in drills, the ground can be readily hoed between by horse or hand hoeing, to kill weeds, and land up the plants, as practised for peas.

For Garden Culture.—When intended to cultivate any of these plants in gardens for variety; sow the seeds in autumn or spring in the borders of shrubberies, woodwalks, wildernesses, thickets, &c. in the places where they are to remain, in patches near the shrubs and bushes to climb thereon, or in open spaces to climb upon sticks.

Faba or Bean Kinds.

To this genus *Vicia*, is now added the article *Faba* or Bean, formerly considered as a distinct genus; but its general characters proving the same as the Vetch, the botanists have lately ranged it as a species of that family, by the name of *Vicia Faba*; consisting of but one species only, which, however, comprises numerous varieties, and is supposed the Common Field or Horse Bean is the original sort, and parent of all the other varieties commonly called Garden Beans.

VICIA Faba. (Annual.)

Faba or Bean.] Hath fibrous roots, upright, thick, succulent, firm stems, rising from one or two to four feet high or more; garnished with large winged succulent leaves of two or three pair of large lobes, without cirrhi or clasps; and numerous papilionaceous flowers all along the sides of the stalk, succeeded by long, compressed pods, containing the Beans.

It is a hardy herbaceous annual, and said to be originally a native of Ægypt; but all the varieties have been long inhabitants of our gardens, and grow freely any where in the open ground.

Varieties.] There are numerous sorts of Beans, all varieties of the same species (*Vicia Faba*) for their general growth and structure, foliage, flowering, fruiting, &c. are exactly the same, and only vary more or less from one another in their size of growth, size of the leaves, pods, and Beans, times of attaining perfection, domestic properties, &c. for all the different varieties are subject to vary exceedingly; and as in the Common Field or Horse Bean, we shall often find some among them that vary considerably from the original, both in substance of stalk and pods; and from these variations the different varieties of Garden Bean were first obtained, and by degrees improved by culture to their present state of perfection; all of which are also very apt to vary from one to the other, unless some attention is observed in saving the seed Beans from the best plants of the

respective varieties; consisting of the following sorts, arranged under three heads, according to their growth and times of attaining perfection, viz. Small early kinds.—Middling kinds.—And large late kinds.

Small Early Kinds.

Those under this head are of the lowest growth, rising only from about a foot and half to two and a half high, and some that scarcely obtain a foot stature; but all very great bearers with small pods and Beans, and are valued for arriving earlier to perfection than any other sorts; and are therefore proper to plant on warm borders in autumn and winter for the early crops to gather in the middle or end of May, and in June.

Early Mazagan Bean.] Grows but half a yard or two feet high, with slender stalks fully loaded from bottom to top with very small pods, arriving to perfection in May or beginning of June.

This is the smallest and earliest of all the tribe of Beans.

Early Portugal or Lisbon Bean.] Grows two feet high or more, with somewhat stronger stalks and larger pods than the Mazagan Bean, arriving to perfection a few days after that sort.

Small Spanish Bean.] Grows stronger than the two former, with somewhat larger pods and Beans, arriving to perfection soon after the Portugal Bean.

Dwarf Fan or Cluster Bean.] Grows low, with several spreading stems from six to ten or twelve inches high, very fully loaded with small pods.

This is chiefly planted for variety or curiosity.

Most of these small Beans if gathered while young, eat very sweet and palatable; particularly the first three sorts, but if suffered to attain full growth, or become the least black-eyed, they eat dry, coarse, and of a disagreeable relish.

These kinds have merit principally to plant for the earliest crops, and the first two or three sorts, are the most eligible for that purpose; but the Mazagan kind is the earliest of all, proper to plant for the first crop, and the Portugal and Small Spanish Bean next; all of which are proper for planting early on warm south borders, or other sheltered sunny exposures, under or near walls, pales, or hedges, every month from October till December or January; in order that if the

the first planting should fail by inclement weather in winter, the others may succeed; and if all the crops should survive the frost, they will succeed one another regularly in bearing; planting them in rows, ranging south and north two feet and a half asunder, an inch and half deep, and two or three inches apart in each row; likewise may plant one row length-ways close along under the wall, &c.

But as to the Dwarf Bean, it is not proper to be planted for any general crop, only a few for variety; and for which purpose it may be planted either in autumn or winter, or in any of the spring or summer months till June or July, in rows two feet asunder, or in patches about the borders.

Middle Size Later Beans.

These sorts are of stronger and taller growth than those of the former class; they rising with stalks from two feet and half to a yard or more high, producing longish, middle-sized pods of different lengths and thickness in the different sorts; being proper to plant for the first main crops, any time from November or December till February or March, to succeed the small early Beans, and will arrive to perfection for the table in June and July.

Long Podded Bean.] Rises with stronger stems, a yard or more high; a remarkable great bearer, producing very long, narrowish pods closely filled with oblong, middle-size Beans.

Varieties of this are.—Early long-podded Bean. — Tall long-podded Bean. — Turkey long-podded Bean, rising with stronger stalks producing the largest pods and Beans.

All these long-podded Beans are remarkable great bearers, very profitable for a family and market, and if gathered for use while they are moderately young, they will eat tolerably sweet and well flavoured.

Broad Spanish Bean.] Grows moderately strong, a yard or more high, producing broadish pods and Beans; is a very good bearer, and the Beans boil tender and well flavoured.

White-blossomed Bean.] Grows two feet and half high, producing entire white flowers, and great abundance of smallish, long, narrow pods, filled with oblong Beans.

This is a good bearer and an excellent table Bean, remarkable for boiling green and tender.

Red-blossomed Bean.] Rises with firm stalks two feet and half high, producing entire red blossoms, succeeded by smallish pods and Beans, not near so palatable to eat as the white blossom kind.

Other less material varieties of middle-size Beans are Nonpareil Bean — Mumford Bean. — Black-blossom Bean. — Green Venetian Bean.

Remark, that of the above varieties of Bean ranged in this class, the first three sorts, Long Pods, Broad Spanish, and the White-blossomed Bean, are the best for general culture; though some of all the others may also be planted occasionally for variety and experiment; and the season for planting all the sorts is, that for the first crop may plant in November or December on some broad warm border, or in any of the most sheltered kitchen-garden quarters, in rows a yard asunder; repeating the planting every month till March in the open quarters or in fields, &c. after that if a longer succession of those sorts is required, plant some every three weeks in an open exposure, till May or June.

Larger Late Kinds, commonly called Broad Beans.

These are the strongest growers of all of the kinds; they rise with thick stems three feet and half high or more, producing large broad pods with Beans proportionably large; and are superior to all the others to plant for the general crops, to succeed the long pods, and others of that class; being proper to plant principally in the spring, or at least not earlier than December or January, for the first crop; and for the general crops, should be planted every month or three weeks, from January or February, until May; and they will arrive to perfection in July and August, and are all most excellent family beans, and always the most saleable in market.

Sandwich Bean.—Grows three feet and a half high, or more, producing large, broad pods, and oblong broadish Beans; and bears abundantly.

Toker Bean.—Grows strong, three feet and a half high, or more, producing long broadish pods, and large oblongish Beans, and the plants bear very plentifully.

Windfor Bean.—Rises with very large, strong stems, three or four feet high, bearing very large, broad pods, having very large

large, roundish Beans, the largest of all the Bean tribe, and the most excellent for eating.

Of this class of large Beans, the Sandwich and Toker kinds, being of less succulent growth than the Windsor, are rather hardier, and may be planted earlier, that is, before Christmas, for the first crop; and any time till April or May, if required; but the Windsor may also be planted any time in January and February, in open weather; and thence every three or four weeks, till the end of April, for the main crops; or may continue planting them till the end of May, to continue the succession of these kinds for the table as long in the season as possible.

All of which large kinds of Beans should be planted in open exposures in gardens and fields; the first plantings before or soon after Christmas may be in the most sheltered, dry situation; after that the succession crops may be planted in any open place, generally planting them by dibble in rows, a yard asunder, or three feet and a half for the large Windsor Beans, four or five inches asunder in each row, and three inches deep.

General Observations.

All the varieties of Bean in the above three classes, are hardy, herbaceous annuals, that will grow in any common soil of a garden, and in the open fields; are all raised annually from seed, planted at several different times, from October till May, in order to obtain a succession of young green Beans for the table three or four months in summer; for by planting early and late kinds every month, from October or November until March; and every three weeks or fortnight, from March till May, June, or July, a constant succession of young Beans is obtained from the latter end of May until September, or beginning of October; though as to the general planting season, that after having planted a few of each sort before Christmas, to come in early, the main crops are planted in January, February, March, and April; and the general season of Beans in full perfection of bearing and goodness, is June, July, and August.

As therefore the utility of Garden-Beans, both for private use, and supply of the markets, is very considerable for about three months in summer, a principal share of kitchen-garden ground and field-land should be allotted annually for the culture of several different crops, succeeding one another in

bearing in regular succession from May or June till August or September, as before observed.

They will all grow freely in any common fertile soil, in a garden or field, but should be allowed always an open, free situation, not much overspread with trees, &c. which would draw them up weak and tall, without yielding any considerable produce; generally allowing the warmest situations for the early crops before Christmas; but the succeeding ones may after that time be planted in any open exposure; and for the late plantings in May and June, &c. should generally chuse the moistest strong land.

As to the general method of planting and culture: all the sorts must be planted in rows, the distance before mentioned, according to the size of the Beans, planted either by dibble, or laid in drills; or for early planting in dry ground, may first draw shallow drills, then plant the Beans in a row along the bottom; allowing from two to four or five inches distance in the row, and from one and a half to three inches deep; and when the plants are come up two or three inches high, land them up on each side of the row with a drawing hoe; and after having advanced nearly to full growth and in bloom, it is proper to top the plants in general, which throws all the nourishment to the embryo pods, and greatly promotes their setting, and forwards their growth; and in the latter crops prevents their being so much annoyed with the small black fly.

VINCA.

Pervinca, or Periwinkle.

This genus is composed of shrubby ever-green trailers and upright growers, for the shrubbery and stove collections, having all durable stems, and branches adorned with oval, oblong, and spear-shaped, ever-green leaves; and monopetalous, salver-shaped, five-parted flowers, at the axillas of the stalk branches.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX is divided into five parts, and permanent.—COROLLA, is monopetalous, and hypocrateriform, or salver-shaped, tubular below with a horizontal, broad-spreading brim, cut into five obtuse segments.—STAMINA, five short inflexed filaments, having obtuse, erect, membranaceous antheræ.—PISTILLUM, two roundish germens,

germens, terminating in one cylindric style, larger than the stamina, having two stigmas, one orbicular, and the other headed, and concave.—PERICARPIMUM, two long, taper, erect follicles, of one longitudinal valve, containing many oblong, cylindric seeds.

There are four species of *Vinca*, three of them common to the English gardens, two of which are hardy, trailing, and declinated plants for the shrubbery; the other is an upright, tender shrub for the stove collection; and are all of the ever-green tribe.

Hardy Kinds.

These have slender stalks, some that trail and extend along the ground, branching numerously, and cover the surface; others grow more erect, with declinated branches; and consist of two species, both evergreens, and natives of England, &c. growing wild, under bushes, hedges, and in woods; but are introduced into most of our eminent shrubberies, to plant as trailers in particular departments, between shrubs, to overspread the ground, and occasionally to mount erect upon support, and form a bushy growth.

¹ VINCA Minor.

Minor or smaller Periwinkle] Hath slender, ligneous, trailing, green stalks, branching and running considerably along the ground, emitting roots at the joints; garnished with oval, spear-shaped, thick, smooth, shining-green leaves, in pairs opposite; and flowers growing singly on proper peduncles, at the sides of the branches, of different colours in the varieties.

Varieties are.] Common green Periwinkle with blue flowers—With white flowers—Double blue flowers—Double white flowers—Double purple flowers—Yellow-striped-leaved, with flowers of all the above colours—White striped-leaved, with flowers of different colours.

² VINCA Major.

Major or Large Green Periwinkle] Rises with shrubby, somewhat erect, green stalks, a foot or two high, with the tops inclining to the ground; large, oval, shining-green leaves, in pairs opposite; and large blue flowers singly on foot-stalks at the axillas of the branches.

Variety.] With white flowers.

Both the species are perennial in root, stem, and branches, with leaves in perpetual verdure, and begin flowering in the spring, about March and April; the flowers moderately

large, each being of one salver-shaped petal, spreading at the brim, and cut into five parts; generally continue flowering in succession several months, and even sometimes in winter, in mild seasons, especiall the *Vinca Major*.

As both the species and their respective varieties are very hardy plants, that prosper under trees and bushes, even in close thickets, &c. and spread and cover the ground; they are proper to plant towards the fronts or verges of shrubbery clumps, wildernesses, and thickets, between the trees and shrubs, next the walks, and on the sides of shady banks, &c. disposed, some to over-run the surface between the shrubs, in particular places contiguous to shady walks, &c. others in patches, to run and entangle with one another in tufts; and some planted entirely detached, particularly the *Vinca Major*; and supported with stakes, and trained with an erect stem a little height, and encouraged to branch out above into a bushy head; in all of which modes, distributing them in the several plantations, they will encrease fast in growth, and effect a very pretty variety at all seasons of the year.

They are all expeditiously propagated by layers, cuttings, and suckers.

By Layers.—Their trailing branches being layed in the ground any how, at almost any season, they will most readily take root; and those of the *Vinca Minor* particularly, multiply exceedingly without care; for the trailing stalks root in the ground at every joint as they extend along, furnishing numbers of good-rooted plants in one summer, fit to plant off in autumn.

By Cuttings.—All the sorts will also readily grow by cuttings of the stalks and branches, planted in autumn or spring, in a shady border, and they will be well rooted by the following autumn.

By Suckers.—They naturally send up suckers from the root in summer, which may be taken up with roots any time in open weather, from autumn till spring, and planted where they are to remain.

Tender Stove Kind,

Consists of one shrubby species, a native of Madagascar, and is retained here in stoves, as an elegant evergreen, and beautiful flowering shrub.

³ VINCA rosea.

Rose

Rose Periwinkle of Madagascar.] Rises with an upright, shrubby, smooth, branching stem a yard or more high; having a brownish bark; oblong-oval, smooth, firm leaves, placed opposite; and large beautiful, rose-like, crimson, and pale-red flowers, singly and in pairs at the sides of the branches being large, spreading above and divided into five segments; appearing very ornamentally from spring till winter, succeeded by ripe seeds in the autumn.

This elegant little shrub being an inhabitant of the hot parts of Africa, in this country must always be kept in pots, in order to be retained in the stove; in which it will flower annually in great abundance, managing it as directed for other shrubby exotics of the stove. See STOVE PLANTS.

It is propagated by seed and cuttings, assisted by a hot-bed.

By Seed.—Sow it in the spring in a pot of light rich earth, half an inch deep, and plunge the pot in a hot-bed or in the bark-bed in the stove; and when the plants are come up about three inches high, prick them separately in small pots and plunged again in a hot bed, &c. giving occasional shades from the sun, and proper waterings; and as they advance in growth shift them into larger pots and keep them always in the stove.

By Cuttings.—In spring or summer take off some cuttings of the young shoots, plant them in pots; and plunge them in any hot-bed or in the bark-bed, and they will root the same year fit to pot off separately, and managed as directed for the seedling plants.

VIOLA.

Violet.

There are many species of Violets, mostly very low, herbaceous, fibrous-rooted perennials and annuals, some considered as flowery plants to adorn the fronts of borders, others for variety and medical purposes, rising with clusters of leaves and shoots but a few inches high, and low stalks the same height, crowned with small, irregular, pentapetalous flowers.

Class and order, *Syngenesia Monogamia*.

Characters.] CALIX is pentaphyllous, with the leaves oval-oblong, sharp at top and obtuse at the base; differently arranged in the different species, and persistent.—COROLLA, is irregularly formed of five unequal petals, the upper one is broadest, obtuse,

and emarginated, having a corniculated or horned nectarium at the base; the two side-petals equal, obtuse, and opposite, and the lower ones larger and reflexed upward.—STAMINA, five small filaments, two of them placed at the upper petal, entering the nectarium by their annexed appendages; and obtuse antheræ that generally coalesce or connect.—PISTILLUM, a roundish germen, slender style and oblique stigma.—PERICARPIUM, an oval, trigonous, obtuse, trivalvour capsule of one cell, containing many oval seeds.

There are more than twenty species of Violets, mostly very low, herbaceous plants; many of them natives of England, and other different parts of Europe, and of America; and but only a few of them have merit as garden plants for ornament or variety, consisting of some perennials and an annual; comprehending the Common Violet, &c. Heart's Ease or Pansies.

Perennial Kinds.

Consist of the common odoriferous Violet and varieties, and three or four others of inferior value, all hardy perennials of humble growth.

¹ VIOLA Odorata.

Odoriferous or Common Sweet-scented March Violet.] Hath a fibrous perennial root, sending up a cluster of heart-shaped leaves and small, creeping, rooting shoots; and amongst them rise slender naked peduncles, three or four inches high, crowned with the flowers of different colours in the varieties, appearing in March.

Varieties are.] Common blue flowered—Pale-purple-flowered—White-flowered—Double blue-flowered—Double, white-flowered.

The flowers of all the varieties impart a fine sweet odour and are used in medicine; though the single flowered kinds are the most odoriferous; but the double flowered varieties are largest and the most conspicuous to sight.

It grows naturally in woods, and under hedges, &c. in England and most parts of Europe, but has been a long resident of gardens as a flowery plant, and for its flowers to use in medicine.

² VIOLA Hirta.

Hairy Inodorous Violet.] Hath a fibrous, perennial,

perennial root, crowned with heart-shaped, hairy, hispid leaves; and amongst them slender peduncles, a few inches high, terminated by larger blue flowers, like the common sort, but without odour; grows wild in woods and hedges in England, &c.

³*VIOLA Palmata.*

Palmated Virginia Violet.] Hath a perennial root, crowned with five-lobed, palmated, or hand-shaped, indented leaves, and low peduncles, supporting white flowers in May or June.

⁴*VIOLA Montana.*

Mountain upright Austrian Violet.] Hath a perennial root; erect stalks a foot high; heart-shaped, oblong leaves; and purple flowers at the axillas of the branches; in April and May.

⁵*VIOLA Calcarata.*

Calcarated Yellow Alpine Violet.] Hath a perennial root, sending up very short stalks, four or five inches high, garnished with oblong, oval leaves: and slender peduncles, supporting yellow flowers streaked with purple; having long spur or awl-shaped nectariums, longer than the petals; flowering most part of summer.

Varieties.] Common yellow purple-streaked-flowered—Plain yellow-flowered—Purple-flowered.

Of the above five species of perennial Violets, the first sort (*Viola odorata*), is the most remarkable, being highly esteemed for its sweet-scented flowers; and is proper to plant on the verge of shrubberies, wood-walks, and in tufts or patches; and as to the other four species, although their flowers are without scent, they, if arranged in concert with the varieties of the common sort, will effect an agreeable diversity.

Though when the common Violet is intended to be cultivated for its flowers to gather, it may be planted in beds, or borders, alone; in rows, a foot asunder, and they will soon encrease into large bunches.

They all flower in great abundance every year in their respective seasons; the flowers are small, irregular, and consist each of five unequal petals; continuing in succession three or four weeks, and are succeeded by ripe seeds in summer and autumn.

The propagation of all the sorts is by parting the roots, and sometimes by seed.

By Parting the Roots.—They all multiply

by the roots; and the common Violet and the other creeping kinds propagate also abundantly by their repent shoots rooting in the earth; they may be parted or slipped in spring, summer, or autumn, as soon as they have done flowering, in moist weather, or early in spring; when each plant may be slipped, or divided into several slips, not too small; and planted either at once to remain, or the weakest may be planted in nursery-beds, to have summer's growth; and in either method each slip will soon encrease into a large tuft, and flower abundantly next year.

By Seed—Sow it either soon after it is ripe, or early in the spring, in a bed or border of light earth, and raked in; and when the plants are come up an inch or two high in summer, prick them out in a shady border, to grow till October, and then planted out finally to remain.

Annual Kind.

One species only come under this head; a well-known, little, tufty, very flowery plant, commonly called Heart's Ease, or Pansey; and is generally considered as an annual, because it often perishes the same year it is produced; yet it also sometimes proves of a biennial or perennial nature, remaining in stalk and leaf all the year, in favourable seasons.

⁶*VIOLA tricolor.*

Violet tricolor, or three-coloured Violet, commonly called Heart's Ease, or Pansey.] Hath a fibrous root, sending up slender, triquetrous, or four-square stalks, branching diffusely, from six to ten or twelve inches high, assuming a bushy, tufted growth; garnished with small, oblong-oval, cut leaves; and at the axillas of the branches numerous variegated, tricoloured flowers, yellow, purple, and white; appearing in constant succession all summer and autumn: grows naturally in cultivated places in the North of England, &c.

Varieties.] Low growing, with small flowers.—Larger, upright, with large flowers.—Variegated, yellow, purple and white-flowered—Yellow-flowered, with purple spots—Purple, with yellow or white spots—White, with yellow and purple spots—Scentless flowered—Sweet-scented flowered.

All the varieties flower very profusely, and variegated many different ways in the same plant;

plant; and the most prevailing colours are yellow, purple, blue, and white; some of which being of a fine velvety hue, particularly the purple; varying in different flowers; and all of which are succeeded by abundance of seed which soon scatters itself in the adjacent ground, and from which numbers of plants naturally rise, without care of culture.

This elegant little plant merits culture in every garden, for the beauty and great variety of its tricoloured flowers; and it will succeed any where in the open borders, or other compartments, disposed in patches towards the front; either by sowing the seed at once to remain, or by putting in young plants previously raised in a seed-bed; they will begin flowering early in summer, and will continue shooting and flowering in succession till winter; and even during part of that season, in mild weather.

It is easily propagated by seed, sowed either at once, where they are to remain, or for transplantation; and when once a few plants are raised, and have flowered and ripened seeds, they will naturally sow themselves, and produce a constant supply of plants.

However, the season for sowing them is in autumn and spring; the autumn sowings come up the same year, stand the winter, and flower early in the spring following; and the spring-sowed plants succeed them in flowering, and continue till winter. Sow them either in patches about the borders, half an inch deep, to remain; or in a bed or border, broad-cast, and raked in; and when the plants are advanced two or three inches high, prick them out, to remain to flower, one or two plants in each patch, which will soon encrease into a large tuft.

VISCUM, Mistletoe.

An hardy, evergreen, parasitical shrub, the branches are dictyotomous, with obtuse spear-shaped leaves, producing flowers growing in spikes and white glutinous berries.

Class and order, *Dioecia Tetrandria*.

Characters.] CALIX of the male flower is composed of four oval equal leaves.—COROLLA, none.—STAMINA, filaments, but form oblong pointed antheræ, each growing to a foliole of the calix.—The female flowers consist of a CALIX, composed of four small leaves, which are oval sessile, deci-

duous, and sitting on the germen.—COROLLA, none.—PISTILLUM, an oblong, three-cornered germen, situated under the receptacles with no style, having only an obtuse stigma.—PERICARPIMUM, a round smooth berry with one cell, containing a single obcordated, obtuse, carnosé, and compressed seed.

We know but of one species.

VISCUM *Album*, Mistletoe.

Hath woody branches of a yellowish colour; they usually grow in pairs, in a sort of a forked manner, dividing from near the base of the main stem, and annually subdividing in a dictyotomous form; at the joints of the divisions grow the leaves, which are spear-shaped, obtuse, of a thick consistence and yellowish green, continuing all the winter; the flowers are produced in short spikes from the wings of the branches, they are small, and of a yellowish colour, they are succeeded by a large white viscidous transparent berry, which is ripe in the winter.

Propagation.

The propagation of this plant is by its seeds when the berries are full ripe; but as they will not grow by any means in the natural earth, being always found either on ash, maple, apple, &c. trees, growing out of their branches, therefore to encrease them the following method should be used: chuse a fine smooth place of the tree, which you would wish them to grow upon; on the part thus chosen stick a few berries, their glutinous matter will affix them, though it would not be amiss to cut the outer bark with a knife, and for a greater chance of success, (as they do not always succeed), several branches of the same tree may be served in the same manner. I have some reason to think that the ill success which frequently attends the propagation of these plants by art is owing to the choice of the berries, for as they are of the dioecious class, bearing male and female flowers on different plants; the berries frequently gathered from male plants which not being near a female plant when in bloom may be deprived of the *farina fecundans*, so necessary for vegetation; therefore in the choice of berries they should be taken from female plants which grow near to those of the other sex.

The mistletoe is encreased in the woods chiefly by birds, particularly the thrush, who
in

in carrying the berries from tree to tree, and lodging some of them they adhere to the bark, and grow. This plant is said to be possessed of many excellent virtues, and is used in nervous disorders, &c.

VITEX. *Agnus Castus*, or Chaste Tree.

Of this genus there is one hardy species cultivated in our ornamental gardens; these are shrubs furnished with digitated leaves and flowers growing in spikes.

Class and order, *Didynamia Angiospermia*.

Characters.] **CALIX**, a short cylindrical monophyllous perianthium, indented in five parts.—**COROLLA**, a ringent petal, with a slender cylindric tube; the limb is bilabiated, both lips are divided into three segments, the middle one being broadest.—**STAMINA**, four capillary filaments, two of which are shorter than the others, having versatile antheræ.—**PISTILLUM**, a roundish germen a slender style, and two awl-shaped stigmas.—**PERICARPIUM**, a globular berry of four cells, each containing a single oval seed.

This tree was much celebrated among the ancients, on a supposition, that the influence of it was conducive to chastity (whence the name); but the moderns know of no such peculiar virtue as has formerly been ascribed to it.

This species is

VITEX, *Agnus Castus*, the Chaste-tree.

Hath pliable branches, whose joints are long, rising to the height of about five or six feet; they are of a brownish grey colour, and are garnished with digitated leaves, composed of several folioles, which are narrow and of a dark green colour, and ending in obtuse points; the flowers are produced at the ends of the branches in whorled spikes, which are pretty long, and of a bluish purple colour; they appear in autumn, but are not succeeded by seeds in this country.

A variety of this is called the broad-leaved *Agnus Castus*, the folioles of which are broader, shorter, and serrated; in other respects there is scarce any difference.

This species is easily propagated either by layers or cuttings any time in the winter, and when they have rooted may be taken up in the spring and transplanted.

VITIS, Vine.

A genus of well known deciduous climbers, of which there are several species, one of which hath many much esteemed varie-

ties; the other kinds are more noticed for their climbing property and singularity than the fruit which they produce.

Class and order, *Pentandria Monogynia*.

Characters.] **CALIX**, a very small perianthium, indented in five parts.—**COROLLA**, five small petals, which are deciduous.—**STAMINA**, five subulate, erect, patent-falling filaments, with simple antheræ.—**PISTILLUM**, an oval germen without a style, crowned with a blunt capitated stigma.—**PERICARPIUM**, a large roundish berry of one cell, containing five hard roundish seeds, narrowed at the base.

Species.

VITIS *Vinifera*.

Vine or grape.] This hath lobate, sinuated, naked leaves, with herbaceous flowers, growing in a racemus which becomes a bunch of red, white, black, &c. berries.

Varieties of this species are.] (1.) *Faly Grape*, this hath a berry, small, round, and black, slightly growing on the branches, but very little esteemed, excepting for its earliness; it ripens soon in August.—(2.) *Black Sweet-water*, hath roundish berries, growing compactly together in small bunches; they ripen in August: the flavour being rich, and skin thin, invites the birds, flies, &c. to prey on them, which (in time) should be guarded against.—(3.) *White Sweet-water*, this is an exceeding fine flavoured grape when perfectly grown, but the berries being liable to outgrow each other, makes the whole bunch incomplete; this ripens about the end of August.—(4.) *Muscadine*, this is one of the finest white grapes which ripen against the common walls in this climate; the bunches are large, the berries are round, and of a very rich flavour; this will ripen in September.—(5.) *Black Cluster Grape*, hath hoary leaves, the bunches are short and very compact; the berries are small, and ripen the end of September.

The following Varieties will not well ripen in this Climate without the Assistance of Glass, &c.

(6.) *Black Frontiniac*, hath shortish bunches, the berries of which grow pretty close together; when ripe are round and of a deep black colour, covered with a mealy bloom; the flavour of this grape is very rich, of a muscat taste, and in very hot summers will ripen naturally in October.—(7.) *Red or griz-*

Ly Frontiniac, hath middling sized bunches, the berries are round, of a red colour, and striped; this grape when thoroughly ripe, is of a most rich and excellent flavour; it rarely ripens in this climate without the assistance of heat.—(8.) *White Frontiniac*, this is a high flavoured grape, and hath a peculiar rich juice when perfectly ripe; the bunches are large, and the berries, which are round, are very closely joined to each other, whereby they are apt to rot each other before they are ripe, which in some measure is owing to the thinness of their skins; it is therefore necessary to thin them out when they are about the size of peas, whereby the sun and air will have freer admittance, and those which are left will be larger, more handsome, and higher flavoured; this grape will not succeed without artificial heat.—(9.) *Muscat of Alexandria*, hath long bunches, with oval large berries; there are two sorts, one with white, and the other with red berries; they are a fine grape, but require a hot-house to perfect the fruit.—(10.) *Hamburg Red and Black*, hath very large bunches, the berries are large and inclining to an oval form; this grape will ripen tolerably out of the stove, if the autumn proves kind, but not before the end of October.—(11.) *Raisin Grape*, hath very large bunches; the berries hang very loosely; they are of an oval form, but will not ripen here without being forced by artificial heat. (12) *Aleppo, or Syrian Grape*. The bunches of this grape are the largest yet known, some weighing at least a dozen pounds, the berries are large and white, growing loosely; they are of a good flavour, and their skins being tough can be kept a considerable time after they are ripe; this kind should be constantly kept in the stove.

The above enumerated varieties, which are of the most approved and esteemed sorts, are sufficient to continue by forcing, and against the common walls, a succession of fruit from May to November, the major part of them being the highest flavoured grapes hitherto known.

To these may be added several other varieties of this species; but as they are little esteemed among the curious in fruits, the mentioning them may pass unnoticed.

Of their Propagation.

The general propagation of grape Vines is either by layers or cuttings; the method

of encrease by layers is practised as follows: in autumn or winter make choice of a strong prolific shoot, of two years growth, arising from near the ground, and of the kind you would wish to propagate; let this shoot be bent down in the earth six or eight inches deep at the part where the last summer's shoot issued from; this should be pegged down to prevent its being disturbed and shortened at the top to two or three eyes; the next autumn following the layer will be sufficiently furnished with roots for transplantation, when it may be cut from the parent plant, and placed where it is intended to remain: but to insure the layer's success by such removal several persons have trained them through the holes of flower-pots, in these they have taken root, and in the winter, if they are separated from the mother plant, they may be turned out of the pot undisturbed, and planted with the roots entire, where it may be thought proper. But the most preferable way to encrease this plant is by cuttings in the choice of which those of a strong vigorous growth, with the buds not far distant from each other, should be preferred, observing, that such cuttings have very thick turgid, blunt buds, as these are most prolific, avoiding those which are not well ripened, or have their buds pointed. In taking off such cuttings, it is proper to cut them an inch or two in the former year's wood, below the place where the last year's shoot is produced from; for at this joint the roots will spring out and form the plant. In shortening these cuttings, observe to cut them in lengths of three, four, or five eyes, according to their distance from each other: the cuttings thus ready (which may be taken from the parent plant any time between November and February) should be laid with their lower part in the ground, and covered in hard weather with litter, where they may remain till the season of planting arrives, which is the beginning of April; they should then be taken up cleansed and planted, where they are intended to remain, and perfect themselves, as they are not to be removed again, whether for walls or vineyard. The soil for grape Vines requires some consideration; if the ground is of a wet nature or a strong stiff clay, it is the most improper for these plants, as the cuttings or layers will grow very luxuriant, but will produce very ill flavoured grapes, owing to the redundancy of moisture.

moisture with which the plants are saturated; a rich light soil is therefore to be preferred; for notwithstanding the notion of many gardeners, in putting a stratum of stones, brick, rubbish, &c. to impoverish the soil with a view to render the Vines more prolific, it only stunts the growth of the plants, and causes the fruit to be small and trifling, whereas, if they have a rich soil the shoots will grow strong, especially where they can have extent to run, and the bunches will be proportionally large and handsome. The soil being ready for the reception of the cuttings, let them be planted against the wall, at about six inches asunder, and at such a depth as but one eye of the cutting may appear above ground, observing to press the ground tight about them, and if the season proves dry let them occasionally have a little water; but where there is the conveniency of a stove in February the cuttings may be planted each in a small pot, and plunged in the bark-bed; here they will quickly take root, and in the course of the summer make a very great progress, so much as to gain a year of those planted in the common ground, observing, as the pots are filled with roots, to shift the plants into others of a size larger, and thus should be occasionally repeated when necessary; the plants thus forwarded should in autumn be inured to the open air, and turned out of the pots with their balls into the places where they are intended to remain. With respect to the aspect these plants require, let it be remembered, that all aspects are improper for grape Vines, excepting the south and south-west, as in other situations scarcely any bunches will ripen in this cloudy changeable climate.

First Year's Management of Cuttings.

When the cuttings begin to shoot let them be examined, and leave only two, if so many arise, those which appear the strongest should be chosen; about a month after, the shoots will have made some progress so as to shew which is likely to be the strongest; this shoot should be preserved, carefully nailing it against the wall, to prevent its being broke by the wind, observing to rub off the other; in the course of the summer, as the shoot advances, continue to keep it nailed up, and let all lateral shoots be stripped off as they are produced; this, with keeping the ground clear from weeds, and occasionally watering

in dry weather, is all that the plants require in their summer's management: when the leaves turn yellow and begin to drop, the shoot which has been reserved should be topped down to two eyes; these will produce shoots the succeeding summer.

Second Year's Management.

The spring following the borders may be enriched and dug up so as not to disturb the roots of the Vines: in April and May the shoots from the eyes which were left will be of a considerable length, each should be tacked to the wall to prevent their being broke by the winds, rubbing off all lateral shoots as they are produced, and this work should be repeated occasionally, till the shoots have done growing, observing to keep the ground entirely free from weeds during the summer. The November following, the operation of pruning should be performed by shortening the weakest of the shoots to two eyes, and letting the strongest be left to four, six or eight eyes according to its strength; for if the principal shoot is very strong, the greater length should it be cut to, and the more probability there is of its producing fruit the succeeding summer.

General future Management.

The same care will be required the third year, &c. for in April or May, according to the forwardness of the season, the shoots of the Vines will have made some progress, which should be properly attended to, this is by displacing all unnecessary shoots, leaving none but those which have the appearance of producing bunches, or furnishing shoots for the succeeding year; these should be laid close to the wall in a regular manner; for, if neglected, the first violent wind may break them off, and if not, the shoots will soon run into confusion; the omission of this necessary work will also be attended with other bad consequences, for the growth of the bunches will be retarded, and the shoots, intended for the supply of the next year, will be so much shadowed and stopped in their growth as to prevent the wood from obtaining its proper ripeness, so as to be able to furnish good bunches in future. The same attention should be paid the Vines in the following months, observing to keep them nailed up as they advance, displacing all useless, straggling,

straggling, and lateral shoots. As they are produced in August, the extremities of the fruit-bearing branches may be shortened, as also those which have run out of bounds to a very great length; this stopping the shoots will assist the bunches to swell their berries out, and forward their ripening; and if that or the former month proves very dry and hot, let them be moderately watered: this will keep the Vine in a ductile state, and be a great addition towards increasing the size of the bunches; but when the fruit is full grown, watering should be disused as it would debase the flavour of the berries. When the grapes are approaching to ripeness they should be guarded from the ravages of birds, wasps, and other insects: they may be protected from birds, by placing a net over the Vine; but this prevents not the wasps, &c. from preying on the fruit, therefore, to hinder these insects from making their depredations, provide some fine crape, which being cut to a proper size, bags may be made so as to fit the principal bunches: black crape is best, as it is of a colour which absorbs the rays of light, and assists by its warmth the ripening of the bunches. But as our climate will not sufficiently ripen the finer sorts of grapes, I shall concisely mention the method of obtaining them in perfection.

Forcing Grape Vines.

Various buildings have been contrived to effect the ripening of those kinds of grapes, which cannot be effected in the open ground, as likewise for the earlier sorts to be fit for the table in May, June, or July. The construction of these kinds of buildings are different, though all answering the same purpose: some are constructed with flues ranging within the wall where the Vines are trained up; but as the Vines would receive more heat at times by being close to the wall than is proper, a lattice work is generally detached therefrom, to which the branches are

trained, and the whole is covered with a range of sloping glass; but the more common method is to train them under the sloping glasses of the pine-apple stove, the Vines are generally planted close on the outside, and trained in through holes contrived for the purpose; in such places there is a certainty of the grapes ripening in perfection, observing always to train fresh shoots from without every year that there may be no want in the choice of wood; their management differs but little from those of the common walls, therefore needs no repetition.

The other species of Vines are those which more excite curiosity than are of real use.

²*VITIS Labrusca.*

Virginian Grape.] Hath a climbing stalk furnished with large, trilobate, heart-shaped leaves, downy on their underside and indented on their edges; the flowers are produced in bunches, and are succeeded by round rough flavoured black fruit.

³*VITIS Vulpina.*

Fox Grape.] The leaves are large and smooth on both sides, of a heart-shaped figure with indented edges; the flowers grow in bunches, and are succeeded by black berries of a very disagreeable stinking flavour.

⁴*VITIS Caciniatis.*

Parsley-leaved Grape.] The leaves of this sort are finely divided, the stem is thick, bearing strong shoots, but the fruit is of no account.

⁵*VITIS Arborea.*

Pepper-tree Grape.] The shoots of this sort are rather weak, but admired for the beauty of its leaves, which are supradecompound, of a fine green colour, are composed of a multitude of delicate folioles; the flowers come out in bunches from the wings of the stalks, and are succeeded by berries of the size and form of pepper.

All these species are propagated by cuttings, layers, or suckers,

W.

WALTHERIA. *Waltheria*.

The plants are woody exotics, from the warm parts of America and India, and retained here in stoves for variety; rising with woody stems, from two or three to four or five feet high, adorned with oval and spear-shaped leaves, and bunches of pentapetalous flowers.

Class and order, *Monadelphia Pentandria*.

Characters.] CALIX, is monophyllous, cyathiform or cup-shaped, five-parted, and permanent.—COROLLA, five heart-shaped, spreading petals.—STAMINA, five short, monadelphous filaments, having distinct antheræ.—PISTILLUM, an oval germen, slender style, and pencilled stigma.—PERICARPIUM, an oboval, bivalved, unilocular capsule, and one obtuse seed.

The species are,

¹ WALTHERIA *Americana*.

American Waltheria.] Rises with a ligneous soft stalk, branching sparingly two or three feet high; large, oval, plicated, sawed, indented leaves; and from the upper parts of the branches round heads, or bunches of yellow flowers, on proper peduncles.

² WALTHERIA *Indica*.

Indian Waltheria.] Rises with a woody stem, dividing and branching eight or ten feet high; having soft, woolly branches; large, oval, serrated, plaited leaves; and smallish yellow flowers, in round bunches, sitting close, without peduncles or foot-stalks.

³ WALTHERIA *Angustifolia*.

Narrow-leaved American Waltheria.] Rises with ligneous stalks, dividing and branching six or seven feet high; spear-shaped sawed leaves; and round bunches of yellow flowers, on proper peduncles.

They all flower in summer, continuing in succession several months; succeeded by ripe seeds in autumn.

All the three sorts are somewhat shrubby; durable in stem and branches, at least for several years; though, as they are generally raised from seed, they arrive to perfection in two years, so as to flower and produce seeds; and sometimes continue several years, and flower annually in summer.

As they are tender exotics from hot countries, they must always be kept in a stove here.

They are propagated by seed, sowed in a hot-bed; and when the plants are fit to remove, plant them separately in pots, and plunge them in the bark-bed; and managed as other woody plants of the stove collection.

WINTERANIA. *Winterania*.

It is of the tree kind; a native of South America; requiring the indulgence of a stove in this country, where it is cultivated for variety; having oblong leaves and pentapetalous flowers.

Class and order, *Dodecandria Monogynia*.

Characters.] CALIX is bell-shaped, trilobed, with the lobes roundish and concave.—COROLLA, five oblong, sessile petals, longer than the calix; and a conical, pitcher-shaped nectarium.—STAMINA, no filaments; but twelve or sixteen linear distant antheræ, affixed to the outside of the nectarium.—PISTILLUM, an oval germen; cylindric style, with three obtuse stigmas.—PERICARPIUM, a roundish, trilocular berry, with two heart-shaped seeds.

There is but one species, which is wholly a fine aromatic.

WINTERANIA. *Canella*] Rises with a thick, woody stem, branching on every side, almost the whole length, growing near twenty feet high; having a lightish-coloured aromatic bark; oblong, obtuse, light-green leaves; and red flowers, in umbellate clusters, at the ends of the branches, succeeded by roundish berries.

This

This tree, being a native of the hot parts of America, must always be kept in a stove in this country, and plunged mostly in the bark-bed.

It is propagated by seeds, and cuttings in pots, and plunged in the bark-bed; also by

layers; though the seeds are generally the most certain method of raising them; which are procured from America by the seedsmen, for the cuttings and layers root but reluctantly.

X.

XERANTHEMUM. Eternal flower.

This genus furnishes herbaceous annuals, and shrubby perennials for the pleasure-ground and green-house collection; rising with upright, branchy stems, from two or three, or four feet high; and some of procumbent growth, garnished with spear-shaped, and oblong, roundish, and oval leaves in the different plants; and compound flowers.

Class and order, *Syngenesia Polygamia, Superflua*.

Characters.] CALIX, a compound flower, having the general calix composed of many long spear-shaped scales.—COROLLA, composed of many hermaphrodite florets in the disc, each consisting of one funnel-shaped petal, five parted at top; and tubular female florets in the radius, more slightly cut at the brim.—STAMINA, five very short filaments, and long cylindric antheræ.—PISTILLUM, a short germen; filiform style, having a bifid stigma in the hermaphrodites; and in the females two reflexed stigmas.—PERICARPIUM, none; each floret succeeded by an oblong, coronated seed, placed on the receptacle.

The plants of this genus derive the name Eternal Flower, from the great durability of the flowers, which being gathered when fully blown, will retain their beauty many months. There are many species, but the most remarkable of which are the following, consisting of a hardy herbaceous annual, and some tender shrubby plants.

Hardy Annual Kind.

Comprises the common Eternal Flower, furnished with several varieties, all hardy annuals.

XERANTHEMUM *Annuum.*

Annual Xeranthemum, or Common Eternal Flower.] Rises with an herbaceous, angular, downy, branching stalk, two or three feet high; spear-shaped, spreading, hoary, close-sitting leaves; and all the stalks and branches, terminated by large flowers singly, of different colours in the varieties, appearing in July, August, and September, and are very ornamental, succeeded by ripe seeds in autumn.

Varieties are.] Large white-flowered.—Purple-flowered.—Double white-flowered.—Double purple flowered.—Double violet coloured.

The flowers of all these varieties are of the compound kind; consisting of many small florets in one common calix, together forming one large flower, which in all the sorts is very ornamental, and in high estimation for the singularity of their durable beauty, even after being gathered; for if gathered when fully blown in dry weather, with part of the stalk to each, and hung up to dry in a shady place, they will retain their respective colours in full beauty all winter, and by placing the stalks in glasses or pots, not with water, but sand to make them stick fast, and placed in any apartment of a house, they will appear very ornamental.

They are all easily propagated by seeds sowed in the full ground, in autumn or spring, or in both seasons; as the autumn raised plants will flower earlier and strongest, and the spring plants will succeed them, and thereby continue the succession of flowers proportionably longer.

Sow them for transplantation in any bed or border of good light earth, either on the surface and raked in, or in drills half an inch

inch deep, and five or six inches asunder; and when the plants are come up two or three inches high, thin out a quantity of the strongest, and prick them either in beds in rows a foot asunder finally to remain; or in patches about the different borders to flower in assemblage with other hardy annuals; giv-

ing water as soon as planted, and repeated occasionally in dry weather till they have taken good root, and they will require no farther care except keeping them clean from weeds.

Or the seeds may be sowed in patches in the different borders, in the places where you intend the plants shall flower.

Y.

YUCCA.

Adam's Needle.

This genus consists of shrubby succulent evergreens of America, both hardy and tender kinds, to diversify the pleasure-ground and green-house collections, rising with upright, thick, woody stems several feet high, adorned at top with clusters of very long, aloe-like, stiff leaves, ending in long sharp spines; and at top, from among the leaves, long spikes of bell-shaped, six-parted, liliaceous flowers.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, none.—COROLLA, is monopetalous, bell-shaped, and divided into six large oval segments.—STAMINA, six very short reflexed filaments, having small antheræ.—PISTILLUM, an oval three-cornered germen longer than the stamina, no style, but an obtuse three-furrowed stigma.—PERICARPIUM, an oblong, triangular, trifid, trivalved capsule of three cells, containing many seeds lying over one another in a double series.

There are four species of Yucca, all of which are of singular growth; they rising with erect stems from two or three to six or eight feet high, terminated by a large tuft of very long leaves, resembling those of the aloe, but much narrower; have all durable stems and evergreen leaves; are natives of different parts of America, and two of them are moderately hardy to grow here in the full ground; and the other two being more tender, require shelter of a green-house in winter.

Hardier Kinds.

¹YUCCA Gloriosa.

Glorious Yucca, or Common Adam's Needle.] Rises with an erect, ligneous, thick stem,

two or three feet high, having very long, narrow, stiff, entire leaves, ending in a long sharp, black-spine, garnishing the stem almost to the bottom and in a large tuft at top; and from the center of the top leaves rises a long branching peduncle, sustaining a panicle of bell-shaped white and purple flowers.

²YUCCA Filamentosa.

Filamentose or Thready Virginia Yucca.] Rises with an upright, thick, ligneous stem two or three feet high, adorned at top with a tuft of very long, spear-shaped, stiff, blunt-pointed, sawed filamentose leaves, emitting long threads from the sides, hanging downward; and from the top of the stem amidst the leaves an erect peduncle or flower-stalk, several feet high, garnished with many large, white, and purple-striped leaves.

Both these species flower in August and September, and make an ornamental appearance, but are not succeeded by seeds in England.

They are natives of North America, the former that of Canada, and the latter of Virginia, and are both tolerably hardy; so as after having little occasional shelter whilst young, for two or three winters, they may be turned out into the open ground in a sheltered situation in the shrubbery; though it is also proper to keep some always in pots, and treated as green-house plants, as a reserve in case those in the open ground should be cut off in very severe winters.

Tender Kinds for the Green-house.

³YUCCA Aloifolia.

Aloe-leaved Yucca.] Rises with an erect, thick, fleshy stem, eight or ten feet high, crowned

crowned with a large tuft of long narrow, stiff, crenated, aloe-like leaves ending in sharp spines; and from the center of the crown of leaves come out the flower-stalk, branching pyramidally two or three feet high, having all the branches terminating in a spike of flowers, purple without and white within, appearing in August and September.

⁴ *YUCCA Draconis.*

[*Dragon Tree-leaved Yucca.*] Rises with an upright, thick, brown stem, three feet high, crowned with long, narrow, serrated leaves ending in spines and nod downward; and in the center of the leaves arise, the flower-stalk very branchy, with all the branches terminating in spikes of flesh-coloured flowers in August and September.

All these four species of *Yucca*, being of singularly curious growth; they are worthy of culture in every good collection, keeping some of all the sorts in pots, to move to shelter of a green-house in winter; as they will afford a conspicuous and entertaining variety in this collection; and some plants of the two first sorts may also, after attaining a little strength and gradually hardened, be planted out in the full ground in some dry

warm situation, sheltered by adjacent shrubs and trees.

As all the sorts are of a succulent nature, they should always be planted in a light dry soil; if somewhat sandy the better.

The propagation of all the sorts is by off-sets and suckers, from the root and head of the plants; also by seed.

By off-sets, &c.—These may be detached almost any time, in spring and summer, and lay them in some dry place for a few days, till the wounded part made by separation from the plant is dried and healed over, then plant them in pots of light sandy compost, and place them in a shady place till they have taken root.

By Seed.—This is obtained from abroad, and should be sowed in the spring in pots of light earth, and plunged in a hot-bed; in which the plants will soon come up, and when they are two or three inches high, prick them separately in small pots of light sandy mould, plunging them also in a hot-bed to forward their growth, assisting them with moderate waterings and fresh air daily; and harden them by degrees to the full air in June and July, to remain till October, then removed into the green-house.

Z.

ZANTHOXYLUM. The Tooth-ach Tree.

This plant is a woody hardy exotic, growing naturally in North America, rising to the height of twelve or fourteen feet, furnished with large pinnate leaves and dioecious flowers, growing in spikes.

Class and order, *Dioecia Pentandria.*

Characters.] *Male flower.*—CALIX, a perianthium deeply cut into five oval coloured parts.—COROLLA, none.—STAMINA, five awl-shaped erect filaments, with didymous, fulcated, roundish antheræ.—*Female flower,* CALIX, as the male, COROLLA, none.—PISTILLUM, a roundish germen, an awl-shaped style, with an obtuse stigma.—PERICARPIUM, an oblong capsule, formed of two

valves and one cell, containing a single smooth roundish seed.

The name of Tooth-ach Tree being applied to this plant, arises from the use made of the bark in cleansing the teeth, and preventing that troublesome disorder among the inhabitants of Canada.

This species is called

ZANTHOXYLUM *Clava Hercules.*

[*Canada Tooth-ach Tree, or Hercules's Club.*] It grows to the height of twelve feet, with a rough bark armed with short spines; the leaves are winged, of a dark green colour, growing irregularly on the branches, each consist of four or five pair of spear-shaped folioles, which are terminated by an odd one; the flowers come out from the ends of the branches

Z I N

branches in loose panicles; they being apetalous have no great appearance, and are succeeded by unilocular capsules, containing the seeds.

Variety.] The ash-leaved Tooth-ach Tree, with oval, oblong, folioles, and prickly mid-ribs.

This tree is propagated by feeds and layers, or cuttings struck in a moderate hot-bed, and afterwards inured to the open air.

ZINNIA.

A genus of annual plants, cultivated for ornamenting the pleasure and flower-gardens, growing with erect stalks, garnished with oblong leaves, and producing radiated flowers.

Class and order, *Syngenesia Polygamia Superflua*.

Characters.] CALIX, the general cup is oval, cylindric, and imbricated, with many blunt, upright, persistent scales.—COROLLA, compound and radiated, consisting of hermaphrodite florets, placed in the disc, and female ones, which are ligulated, and form the rays.—STAMINA, of the hermaphrodites are five short filaments, with cylindric tubulose antheræ.—PISTILLUM, an oblong aristated germen, with a slender semibifid style, and two erect obtuse stigmas; in the female flowers the germen is oblong and triquetrous, with a capillary style, and two recurved stigmas.—PERICARPIUM, the calix containing oblong solitary seeds crowned with down, and placed on a paleaceous receptacle.

Of this genus there are two species.

¹ZINNIA *Pauciflora*.

Yellow Zinnia.] The root of this plant is fibrous, from which arises the stalk to about three feet high; it is woody below, and branches upwards, which are placed opposite; these are furnished with oblong leaves of a pleasing green colour, the flowers terminate the ends of the branches on long foot stalks; they are of a yellow colour, which decays till the seeds are ripe.

²ZINNIA *Multiflora*.

Red Zinnia.] This plant is also annual; the stalk rises erect with upright branches, these are channelled and hairy; the leaves are oval, lanceolate, and placed opposite; the flowers come out at the extreme part of the branches, the florets of the disc are yellow, and those which form the rays are of a dusky

Z Y G

red; these continue till the seed is ripe, which is in autumn.

These plants being annual are propagated from the seeds which should be sown on a slight hot-bed; in March, and afterwards, when the plants arising are a few inches high, they should be pricked out on another bed previously prepared to receive them; here they may remain till the advance of summer, when they may be taken up and transplanted in the borders of the pleasure or flower garden, where they will blow and complete their seeds for the next year.

ZYGOPHYLLUM.

Bean Caper.

It furnishes herbaceous and woody succulent exotics of Asia and Africa, cultivated here for variety in the pleasure ground and green-house collections: rising with erect stalks three or four feet high, adorned with oval, oblong, and spear-shaped, fleshy, succulent leaves, and pentapetalous flowers along the sides of the branches.

Class and order, *Decandria Monogynia*.

Characters.] CALIX, five oval, obtuse, concave, erect leaves.—COROLLA, five obtuse petals emarginated at top, and a ten-leaved closed nectarium, which includes the germen.—STAMINA, ten awl-shaped filaments and oblong incumbent antheræ.—PISTILLUM, an oblong, germen, awl-shaped style, crowned by a simple stigma.—PERICARPIUM, an oval, pentagonous, quinquevalvulous capsule of five cells, having many roundish seeds.

There are several species, one is herbaceous and moderately hardy, with perennial roots and herbaceous annual stalks; the others are of a woody durable growth, and tender, requiring shelter of the green-house in the winter. The principal sorts in the English gardens, are the following.

¹ZYGOPHYLLUM *Fabago*.

Fabago or Common Bean Caper.] Hath a thick, fleshy, deeply striking, perennial root; upright, round, smooth, jointed, herbaceous, green stalks, three or four feet high; garnished with oval, smooth, fleshy, blueish-green leaves two or three together on each petiole; and reddish flowers, by two or three together at the axillas of the stalks, appearing in July, succeeded by long capsules, containing the seed, ripening in autumn.

Z Y G

It is durable in root, but the stalks, being herbaceous, perish every autumn; is tolerably hardy, only requiring a little shelter in winter when young, afterwards may be planted in the full ground in the borders in any dry light soil, there finally to remain; where they will abide many years by the root, and send up stalks and flower abundantly, and ripen seeds.

As it is of a succulent nature, it should have a dry rubbishy soil.

It is propagated by seeds sowed in the spring; some in a hot-bed to bring them forward, and some on a warm border; and when the plants are come up about two inches high, plant some out in small pots separately, and plunged into a hot-bed to facilitate their rooting, and forward their growth; but harden them by degrees to the full air; others may be planted in a warm border to take their chance, allowing those in the pots shelter of a garden-frame in frosty weather, and in spring some of them may be turned out into the full ground where they are to remain.

Tender Green-house Kinds.

These are mostly of a shrubby nature, durable in root, stem, and branches, garnished with succulent leaves.

²*ZYGOPHYLLUM Sessilifolium.*

Sessile-leaved African Bean Caper.] Rises with an upright woody stem, branching numerous and irregularly, three or four feet high; oval, spear-shaped, thick, smooth, succulent sessile leaves, surrounding the branches by fours; and yellow flowers on long, slender footstalks at the sides of the branches, in succession great part of summer.

Varieties.] Yellow flowered—Sulphur-coloured flowers—White-flowered—Copper coloured, having mostly a reddish or brown

Z Y G

spot near the base of each petal.

³*ZYGOPHYLLUM Morgsana.*

Morgsana, or Purslane-leaved Ethiopian Bean Caper.] Rises with a shrubby stem, dividing and branching irregularly, three or four feet high; oval, thick, obtuse succulent leaves, surrounding the branches by fours; and sulphur-coloured flowers on long foot-stalks from the sides of the branches, appearing most part of summer.

Both these tender species being natives of the warm parts of Africa; they require shelter of a green-house in this country in winter, planting them in pots of light sandy earth, as being succulent, and manage them as other plants of similar quality. See GREEN HOUSE PLANTS.

They are propagated easily by cuttings and by seed.

By Cuttings.—These may be planted any time in the spring or summer; if in spring about March or April, plant them in pots, and if plunged in a hot-bed, and frequently watered, they will quickly emit roots, and shoot at top; and if in the summer months, plant them in a shady place, or in pots placed in the shade, giving frequent waterings, they will also take good root; and in either method pot them off separately towards autumn in order to be moved into the green-house or glass case, in October.

By Seed.—The plants sometimes produce seeds in this country, or are procured from abroad by the seedsmen; sow them in spring in pots of light earth, and plunge them in a hot-bed, where they will soon come up, and when a little advanced in growth, prick them in separate small pots, watered and plunged again in the hot-bed till well rooted, then hardened gradually to the full air in June and July, to remain till October, then placed in the green-house, &c.

ADDENDA.

A D D E N D A.

A.

A GARIC. Mushroom. See the article SPAWN.

ALSTROEMERIA.
Consists of stove plants, which are perennial and herbaceous, bearing very ornamental hexandrious flowers.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, none.—COROLLA, hexapetalous and sublobed, the three outward petals are wedge-shaped and retuse, the interior petals are spear-shaped, the two lower ones of which are tubulose at the base. STAMINA, six subulate, declining, unequal filaments, with oblong antheræ.—PISTILLUM, a top-shaped, six-angled germen, which is placed below the flower; the style is declining and slender, topped with three oblong bifid stigmas.—PERICARPium, a roundish fixangular mucronated capsule, opening with three valves, containing three cells, filled with many globose seeds: there are three species of this genus.

¹ALSTROEMERIA *Pelagias*.

Peruvian spotted purplish Alstroemeria.] Hath a fibrous root, from which arise many herbaceous stalks, about three feet high; on these the leaves are pretty thick set, and continue all the winter, each of which are oval, spear-shaped, reflexed, and of a dark-green colour, from the extremities of the branches, the flowers come out, two or three together, on long foot-stalks, they are composed of six petals; the outer ones are white, with a large, reddish purple spot in the middle of each; the interior petals are spotted with purple; they are succeeded by a hexangular capsule, containing many seeds.

²ALSTROEMERIA *Ligita*.

Striped Alstroemeria] Hath a rising stalk, with spear-shaped leaves, and striped purple flowers.

³ALSTROEMERIA *Salifilla*.

Climbing Alstroemeria.] Hath a twining stalk, with spear-shaped leaves placed alternately; the flowers come out from the sides of the stalks, and are of a purple colour.

These plants are retained in the stove, though they will thrive in the green-house; the beautiful flowers come out in May, and frequently blow all the summer months; they

are propagated by cuttings feeds or parting their roots, which may be done any time in the spring, giving them the assistance of a hot-bed.

AMETHYSTEA.

We know but of one species of this genus; it is a native of Siberia, and an hardy annual.

Class and order, *Diandria Monogynia*.

Characters.] CALIX, is monophyllous, tubulately companulated, and five-parted at the margin.—COROLLA, monopetalous and ringent.—STAMINA, two slender filaments, and simple antheræ.—PISTILLUM, quadrid germen, with a single style topped with two acute stigmas.—PERICARPium, none; the cup containing four obtuse seeds.

This plant rises with an upright stalk to the height of about a foot, with a few lateral branches towards the top, on the extremities of which the flowers are produced in small umbels of a rich blue colour, which make an elegant appearance; the leaves are trifid, serrated, and of a dark green; the flowers come out in June or July, and when the seeds are ripe, may be immediately sown, where the plants are to remain, as they will not thrive well by transplanting.

AMYGDALUS PERSICA.—Add after *Early Newington Peach*,

Galland Peach.] A middle-sized round fruit, of a very deep red all over, esteemed the finest flavoured Peach of any yet known; ripe the beginning of August.

ANNUAL PLANTS. Such as are only of one year's duration, rising from seed in the spring, &c. arrive to full growth the ensuing summer, and produce flowers and seed; then totally perish, root and top, in autumn or winter following.

Plants of the Annual Tribe are very numerous, principally all of the herbaceous kind; consisting both of esculents, and of the flowry race, as ornamental plants, which latter are commonly called simply *Annuals*, and of which there are both hardy and tender kinds; the hardy Annuals being such as will grow from seed in the open ground; and the tender Annuals are such as require to be raised and forwarded in a hot-bed, as is explained in the culture of the respective sorts in their respective genera.

CALLICARPA.

C.

CALICARPA,—*add*,

Characters.] CALIX, monophyllous and bell-shaped.—COROLLA, monopetalous and tubulose, with the brim cut into four obtuse spreading parts.—STAMINA, four slender filaments double the length of the corolla, with oval antheræ.—PISTILLUM, a roundish germen, the style slender, with a blunt stigma. PERICARPIUM, a smooth round berry, containing four oblong seeds.

After cuttings, ibid. add,
but should be sheltered from the severity of hard weather, particularly when young.

CHIRONIA, shrubby African Centaury.

This genus consists of two species of shrubs, which are natives of Africa, and require some shelter in winter.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, monophyllous, divided into five parts.—COROLLA, monopetalous, tubular, with the border cut into five spreading parts.—STAMINA, five broad filaments, growing to the top of the tube, and topped with oblong antheræ.—PISTILLUM, an oval germen, slender style, and a capitated stigma.—PERICARPIUM, oval and bilocular; the seeds are numerous and small.

The species are,

¹CHIRONIA *baccifera*.

Shrubby berry-bearing African Centaury.]

Chironia with round-jointed stalks, divided into various branches upward, and furnished with short, narrow, fleshy leaves; the flowers are of a fine red colour, and produced at the extremities of the branches; they continue in succession all the summer and autumn months, and sometimes in favourable seasons produce seeds.

²CHIRONIA *frutescens*.

Shrubby African Centaury with capsules.]
Chironia with a round stalk, producing several erect branches, and growing to the height of between two and three feet; at the ends of each shoot, the flowers which are tubulous and spreading are produced; they are of a bright scarlet colour, and make a gay appearance; they are in bloom all the summer, and the seeds ripen in autumn.

Propagation.

Both sorts are raised from seeds on a hot-bed in the spring, and, when arrived at some

tolerable size, may be inured to the open air in summer, but require shelter in an airy glass-case in winter, and must have but little water; the soil they best thrive in is a light sandy earth: they may also be propagated by cuttings.

CHRYSOBALANUS, Cocoa Plum-tree.

A genus of trees growing in several parts of the West Indies.

Class and order, *Icosandria Monogynia*.

Characters.] CALIX, monophyllous and bell-shaped.—COROLLA, consists of five oblong, spreading petals, inserted in the calix.—STAMINA, many filaments inserted in the calix, and small twin antheræ.—PISTILLUM, an oval germen, with a style of the shape and length of the stamina, with a blunt stigma.—PERICARPIUM, a large oval berry of one cell, containing a rough oval nut.

The species are,

¹CHRYSOBALANUS, *Itaco*.

Cocoa Plum-tree.] Chrysobalanus with a shrubby stalk rising about eight or ten feet high, from which issues several branches, which are furnished with stiff, oval, indented leaves from the wings of these, and at the separation of the branches, the flowers come out in loose bunches; they are small and of a white colour; these are succeeded by berries which are of different colours, and of the size of a middling plum.

²CHRYSOBALANUS *Purpurea*.

Chrysobalanus with decomposed leaves.] This species hath a shrubby stalk like the former, but differs in the foliage, being winged and branched, each branch consisting of six or seven pair of oval entire folioles.

Propagation.

These trees are propagated by the nuts, which must be procured from the West Indies; they must be sown in the spring on a hot-bed, and when the plants have risen high enough; they may be transplanted singly into pots, and plunged into the bark-bed in the stove, observing to shade them from the sun till they have taken fresh root, in which place they must always be continued.

CHRYSOPHILLUM, Star-apple-tree.

It grows naturally in the West Indies, where it is cultivated for its fruit, which is astringent and rough to the palate, unless mellowed by keeping, when it becomes very agreeable to the palate.

Class

A D D E N D A.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, a small cup divided into five parts. — COROLLA, monopetalous and bell shaped, with the border cut into five parts. — STAMINA, five subulate filaments, placed in the tube of the corolla, and topped with double roundish antheræ. — PISTILLUM, a roundish germen, with a very short style and blunt stigma. — PERICARPIUM, a large round berry, containing ten cells, in four or five of which are deposited a compressed hard seed.

The species are,

¹CHRYSOPHYLLUM, *Cainito*:

Gold-coloured leaved Star-apple-tree.] This species in its native country rises to thirty or forty feet in height, furnished with many slender declining branches, on which grow oval striated leaves, whose under side is downy, and of a gold colour; the flowers are produced in oblong bunches from the extremity of the branches, and are succeeded by a large berry.

²CHRYSOPHYLLUM, *Glabrum*.

Mexican Medlar, or Sappatilla.] The difference between this and the other species is, that it grows not near so large, the under part of the leaves are quite smooth, and the fruit is oval, about the size of a damson; both species retain their leaves all the year.

Propagation.

The propagation of these trees are by seeds from their native country, which must be sown in pots and plunged in a hot-bed, and when the plants have arisen to three or four inches high, they should be planted singly into small pots, and replunged into the bark-bed, care being taken to shade and water them till they have got a fresh root, which they will soon do; after this they should have a proper share of air and water, according to the weather, and on the approach of winter, admitted into the stove, where they should be treated as others of the like nature are.

COCCOLOBA, *Sea-side Grape*.

This genus of plants grow on the sea shores in divers parts of the West Indies, and are here admired for the largeness and shape of their leaves which are evergreen and very ornamental in the stove with other curious plants.

Class and order, *Ostendria Trygynia*.

Characters.] CALIX, a monophyllous cup,

divided into five parts. — COROLLA, none. STAMINA, consists of eight subulate spreading filaments, which are shorter than the cup; the antheræ are roundish and double. — PISTILLUM, a three-cornered oval germen, with three short, slender, spreading styles, and simple stigmas. — PERICARPIUM, none, the cup containing the seed, which is an oval-pointed nut of one cell.

The species are,

¹COCCOLOBA *Uvifera*.

Shining-leaved Sea-side Grape.] The leaves are round, thick, and heart-shaped, about six or seven inches diameter; it grows on the sea shores in most of the West Indian islands.

²COCCOLOBA *Rubescens*.

Downy-leaved Sea-side Grape.] With orbicular hairy leaves, about eight inches long, and three or four broad; it is a native of New Spain.

³COCCOLOBA *Excoriata*.

Mountain Grape.] With light-green, oval, heart-shaped leaves, whose foot-stalks are joined to the under part; it grows in Campeachy.

⁴COCCOLOBA *Tenuifolia*.

Small-fruited, Sea-side Grape.] With oval membranaceous leaves of a light-green, about six inches long and three broad; it is a native of Jamaica.

⁵COCCOLOBA *Punctata*.

Veined-leaved Sea-side Grape.] With lanceolate oval leaves, three or four inches long, and indented at their foot-stalks; it is a native of New Spain.

All the species are of the shrubby kind, inclinable to be woody; they rise six or seven feet high, and bear grape-like bunches; the fruit of some of the species are eaten in the West Indies, but they produce none here.

CORDIA, *Sebesten*.

It consists of four or five species, one of which is worthy of notice.

Class and order, *Pentandria Monogynia*.]

Characters.] CALIX, a monophyllous tubulated cup, dentated at the top. — COROLLA, monopetalous, and funnel-shaped. — STAMINA, five subulate filaments, with oblong antheræ. — PISTILLUM, a roundish-pointed germen, with a single style the length of the stamina, and divided at top into two parts, each of which terminate with a blunt stigma. — PERICARPIUM, a globose-pointed drupe, fastened to the cup. — SEMINA,

SEMINA, a furrowed nut, containing four cells.

The *Cordia Sebesten* rises eight or nine feet high, with divers stems of the shrub kind, which, toward the upper parts, are furnished with rough ovato-oblong leaves of a deep green colour, and placed alternately on short foot-stalks; the flowers are produced at the extremities of the branches in large clusters on branching foot-stalks, each sustaining one, two, or three flowers, of a rich scarlet colour; but they produce no seed in this country.

Propagation.

As this plant is a native of the West Indies, the seeds must be procured from thence, as by seeds all the species are propagated; these obtained should be sown in pots, and plunged into a hot-bed, and about two months after, the plants arising will be fit to transplant singly, and again plunged; afterward they must be removed into the stove, where they should constantly be kept.

CROTOLARIA.

We have no English name for this genus, which consists of several species, which are all natives of foreign parts; but as the flowers of most of them have no great beauty, we shall only notice one specie which deserves observation, this is *Crotolaria Liburnifolia*.

Class and order, *Diadelphia Decandria*.

Characters.] CALIX, a large cup divided into three parts.—COROLLA, is papilionaceous, consisting of a large, pointed, heart-shaped standard, two ovate wings, shorter by half than the standard, and an acuminate keel the length of the wings.—STAMINA, ten diadelphous filaments rising upwards, crowned by simple antheræ PISTILLUM, an oblong, reflexed, hairy germen, a simple style, rising upwards, and an obtuse stigma.—PERICARPIUM, a short, turgid, bivalvular pod, containing one or more roundish kidney-shaped seeds.

Crotolaria Liburnifolia, rises with a woody stem branching upwards, and furnished with oval pointed leaves about two inches long and one broad, of a light green, and are trifoliate; the flowers are produced at the ends of the branches in spikes, and are of a beautiful yellow colour; they blow the best part of the summer, and are succeeded by the pods and seeds; this plant being a native of India, re-

quires a stove for its protection, though it will endure the open air in the warm summer months: it is propagated either by seeds or cuttings in the spring, but must be assisted by a hot-bed.

D.

³DAPHNE *Cneorum*.—*Add*,

Daphne with short woody stalks, of about nine or ten inches height, and furnished irregularly with small lanceolate leaves of a dark green; the flowers are produced in clusters along the extremities of the branches, and are of a purple colour; the scent of them is very agreeable, and as a farther recommendation they blow early in the spring when other flowers are scarce.

⁴DAPHNE *Indica*.

Daphne with a whitish woody stem, seldom growing above two feet high, with lateral upright branches, which are garnished with dark evergreen leaves, about an inch and a half long, and an inch broad, these are placed opposite to each other, they are smooth and of an oblong oval form; the flowers come out as the other sorts, and are of a dusky colour.

The third sort must be raised from seeds; they thrive best where they are sown, as they rarely succeed by removing. and as they make an elegant pot flower, it would be eligible to sow some seeds in small pots, when they may at any time be shifted with balls so as not to miscarry.

The fourth sort is too tender to bear the open ground, it should therefore be planted in a conservatory, where it will thrive best; this plant is rather of stubborn growth, it is raised from seeds from abroad, which should have a hot-bed to vegetate them.

DECIDUOUS PLANTS.

Such as cast their leaves in winter, and is applicable to trees, shrubs, and herbaceous vegetables; and each of which tribes comprehend numerous Deciduous Plants; most of our valuable forest and fruit-trees are of the Deciduous kind; likewise the greater number of our most beautiful flowering shrubs that adorn the shrubberies are Deciduous; as are also a very great share of the flowery perennials, both bulbous and fibrous-rooted kinds.

DIOSPYROS, Date Plum.

This genus are very ornamental plants for the shrubbery; the leaves being of a fine green

green make a good contrast with those of other trees whose shape and tints are different.

Class and order, *Polygamia Dioecia*.

Characters.] *Hermaphrodite*, CALIX, a large, monophyllous, permanent, obtuse cup, divided into four parts.—COROLLA, one large pitcher-shaped petal, divided into four acute spreading angles.—STAMINA, eight short, setaceous filaments, firmly joined to the receptacle with oblong antheræ, which are destitute of farina.—PISTILLUM, a roundish germen, a single, quadrifid, permanent style, longer than the stamina, and an obtuse bifid stigma.—PERICARPIUM, a large globular berry of eight cells placed on the large patent cup.—SEMINA, the seeds are single, roundish, compressed, and very hard.

Male Flowers in distinct Plants.

CALIX, a small, erect, acute, monophyllous cup.—COROLLA, a three-cornered, pitcher-shaped, leathery petal, cut into four roundish, revolute segments.—STAMINA, are eight short filaments, inserted in the receptacle, having long, acute, twin antheræ.

The species are,

¹DIOSPYROS *Lotus*.

Indian Date Plum.] *Diospyros* with an upright stem, and grows to the height of twenty feet; the branches are covered with a smooth whitish bark, the buds on the younger shoots begin to swell soon after the leaves are shed; the leaves are of a bright green, their figure is oblong, ending in a point, and are placed alternately on the branches, continuing green till they fall off in autumn; the flowers have no great beauty, they are of a redish colour, and are succeeded by large black berries, which are eatable like the medlar when in a state of decay.

²DIOSPYROS *Virginiana*.

Pisbamin-Plum] *Diospyros* with whitish smooth branches, growing in an irregular manner to the height of twelve or fourteen feet; the leaves are of a fine shining green, and five or six in length; at the time of their shedding, which is early in autumn, they turn to a purplish red, the flowers are like those of the other species, and are succeeded by fruit, which are also eatable.

Propagation.

They are both raised from seeds, which need not the aid of a hot-bed, though they would come up more certain and quicker with one: in such case they should be sown

in pots, and when inured to the open air by degrees, should remain undisturbed until autumn, or rather till the spring, when they may be transplanted into a warm part of the nursery, there to remain till they are arrived to a size fitting for the plantation they are designed for.

F.

⁴FRAXINUS *Integrifolia*.—*Add*,

Entire-leaved Ash.] Hath oval-pointed entire leaves, grows to thirty feet; but as it has been discovered but a few years in Yorkshire, and not flowered, botanists have not yet determined whether it is a distinct species, or only an accidental variety of the common ash; though it certainly claims a specific title, as all the other species are furnished with winged leaves.

G.

GORTERIA.

Consists of shrubby plants, with naked branching flowers and downy seeds.

Class and order, *Syngenesia Polygamia Frustanea*.

Characters.] CALIX, the common cup is monophyllous, and formed of prickly scales placed imbricatum.—COROLLA, is radiated and compound; the hermaphrodite florets fill the disc, which are radiated with a few females.—STAMINA, five short filaments, with cylindric antheræ.—PISTILLUM, a villose germen, slender style, and a bifid stigma.—PERICARPIUM, the calix which remains, the same containing solitary roundish seeds, crowned with down.

The species are.

¹GORTERIA *Ringens*.

This is a low-growing plant, whose woody branches spread on the ground, and furnished with winged lanceolate leaves, parted into three or five parts at their extremities; the flowers which proceed from the branches are radiated, of a fine deep yellow colour, and appear in May.

²GORTERIA *Fruticosa*.

Gorteria with a shrubby stalk, which rises about three feet high, furnished with slender branches, on which are placed oblong indented leaves, armed at the edges with weak spines; their under-part are woolly, but smooth and green on the upper surface; the branches bear the flowers at their extremities, which are of a golden colour, and blow in June.

There are two or three other species, which are scarce worth mentioning.

They are propagated by cuttings in the summer months, being covered with glasses, and must be sheltered in a green-house in winter.

GUILANDINA, *Bonduc*, or Nickar-tree.

There are several species of Guilandina, but the kind we shall mention here is hardy, and will endure our severest winters, the others being natives of the hottest climates.

Class and order, *Decandria Monogynia*.

Characters.] **CALIX**, a monophyllous bell-shaped cup, cut at the brim into five parts.—**COROLLA**, five spear-shaped, concave, sessile petals.—**STAMINA**, ten awl-shaped erect filaments, inserted in the cup.—**PISTILLUM**, an oblong germen, with a slender style, and simple stigma.—**PERICARPIUM**, A rhomboidal, swelling, compressed, unilocular pod, having a convex future on the upper-side, containing one cell, and divided into many partitions by transverse valves, in each of which are lodged a hard, roundish, and compressed seed.

The hardy species is,

GUILANDINA Dioica.

Canada Bonduc or Nickar-tree.] The Bonduc rises with a stem, which is firm and erect, to the height of fifteen or twenty feet, from which issues several branches, having a smooth, bluish, ash-coloured bark; the leaves are bipinnate, of a dark-green, and the folioles are large, smooth, entire, and ranged alternately on the midril; the flowers are dioecious, there being male and female on different plants; they appear in July or August, but produce no seeds here.

Propagation.

This species is increased by seeds procured from Canada and sown in the spring, by layers in autumn, slitting them at a joint, or by the roots being cut and turned up in winter.

H.

HALESIA.

Consists of two species, both of which are deciduous, ornamental, hardy shrubs, fitting to intermix with others in shrubbery plantations.

Class and order, *Dodecandria Monogynia*.

Characters.] **CALIX**, a small, permanent, monophyllous cup, divided at the edge into four parts.—**COROLLA**, is ventricose, bell-shaped, and monopetalous, with the mouth

cut into four obtuse spreading parts.—**STAMINA**, are twelve subulate, upright, filaments, topped with oblong blunt antheræ.—**PISTILLUM**, an oblong germen, laying in the bottom of the cup; the style is slender, and crowned with single stigma.—**PERICARPIUM**, an oblong corticated nut, with four membranaceous angles, and containing two cells, in each of which are deposited a single seed.

The species are;

¹**HALESIA Tetraptera**.

Quadrangular-fruited Halesia.] This species frequently produces two or three stems from one root, which rise to fifteen feet high, or upwards; the branches which spring from the principal stems are furnished with lanceolate oval leaves, jagged on their edges; the flowers which are of a white colour are produced in clusters on the side of the branches, and the fruit is four-cornered.

²**HALESIA Diptera**.

Two-angled Halesia.] Hath the stems like the first species; the leaves are oval, and their foot-stalks smooth; the fruit has two edges, which are winged.

This genus is propagated by seeds or layers; the seeds should be sown in the spring on a hot-bed, and treated in the same manner as many other Carolina plants are of the same nature. They may also be raised by laying; this may be done in autumn, by the last summer's shoots being brought down, first notching them in a joint, and the autumn following they will be fit to be taken off, and transplanted into the nursery, where they may remain till arrived to a proper size to transplant for good.

L.

LAWSONIA.

Consists of two species of tree-like plants, producing bunches of octandrious flowers.

Class and order, *Octandria Monogynia*.

Characters.] **CALIX**, a small quadrifid permanent cup.—**COROLLA**, four oval spear-shaped petals, which are flat and spreading.—**STAMINA**, eight slender filaments of the length of the corolla.—**PISTILLUM**, is a roundish germen, with a single persistent style, crowned with a capitated stigma.—**PERICARPIUM**, a globular capsule ending in a point, containing four cells, in which are many angulated pointed seeds.

The species are,

¹**LAWSONIA**

LAWSONIA Inermis.

Egyptian broad-leaved Lawsonia.] This rises with a shrubby stalk, eight or nine feet high, the branches are slender, and are produced opposite to each other; the bark is of a yellowish colour, and they are furnished with small-pointed leaves of a pale green; the flowers come out at the end of the branches in loose bunches of a greyish colour, which are succeeded by capsules and seeds.

LAWSONIA Spinosa.

Malabarian thorny Lawsonia.] Is a tree which grows to the height of sixteen or eighteen feet; the bark is of a light grey colour, the branches are produced as in the former species, and armed with strong spines; the leaves are irregularly situated along the branches; they are of an oval-oblong figure, and of a light green, the flowers are produced from the sides of the branches in loose bunches, and are of a light-yellow colour; these are succeeded by capsules of four cells, which contain the seeds.

Both species are propagated by sowing the seeds in the spring on a hot-bed; and when the plants are up, and got to about three or four inches high, they should be transplanted singly into small pots, and replunged, observing to shade them till they have taken fresh root; they will bear the open air during the hot months in summer, and may be placed in the coolest part of the stove in winter, minding to give them but little water.

LEONURUS, Lion's-tail.

This consists of herbaceous perennial plants, the flowers of which are of the labiated kind, and produced in whorls; there is one beautiful species which is cultivated in our gardens.

Class and order, *Didynamia Gymnospermia.*

Characters.] CALIX, a monophyllous, tubulous, pentangular cup, which is permanent, and indented in five parts at the top.—COROLLA, a ringent petal, the tube is narrow, the limb gaping, and the chaps long; the upper-lip is semicylindrical, long, concave, gibbous, rounded at the top, hairy, and entire; the lower-lip is reflexed, and divided into three spear-shaped segments, which are nearly equal.—STAMINA, four filaments concealed under the upper-lip, of which two are shorter than the others; these are crowned with long compressed, bifid antheræ.—PISTILLUM, four germens, a fi-

liforme style, the length and situation of the stamina, with a bifid acute stigma.—PERICARPIUM, none; the seeds are lodged in the cup.—SEMINA, four oblong seeds, convex on one side, and angular on the other.

The specie is,

LEONORUS Indicus.

Scarlet Lion's-tail.] The root of this is perennial, from which arises several annual square stalks, near a yard in height; these are garnished with spear-shaped serrated leaves, which grow opposite to each other at the joints; the flowers are of a rich scarlet, they appear in June or July, and frequently continue blowing the remainder of the summer.

This plant is propagated by dividing the roots in autumn; they grow best in a moist soil, and a shady situation, but not under the drip of trees; they may also be raised from seeds sown either in autumn or spring.

LEPIDIUM. Garden Cress.

Consists of hardy herbaceous annuals of great estimation as small-sallad herbs; they rising with many small multifid leaves near the ground; and when they shoot to stalk, rise a foot or more high, terminated by many small, tetrapetalous, cruciform flowers, succeeded by small ovalish seeds.

Class and order, *Tetradynamia Siliculosa.*

Characters.] CALIX, a four-leaved deciduous cup.—COROLLA, four small, oval, cruciform petals.—STAMINA, four long and two short filaments, and simple antheræ.—PISTILLUM, a heart-shaped germen, simple style and obtuse stigma.—PERICARPIUM, a nearly heart-shaped, compressed, bilocular pod, having very small, oval, pointed seeds.

There is only one species of Garden Cress, comprehending three varieties, all excellent sallad herbs.

LEPIDIUM Stativum.

Cultivated or Common Garden Cress.] Rises with small oblong leaves near the ground, multifid or cut into many parts; and erect stalks a foot or two high, terminated by many small flowers in summer, succeeded by numerous small red seeds, ripening in June, July, &c.

Varieties.] Common small multifid-leaved Cress, having the leaves finely divided.—Broad-leaved Cress, having the leaves much broader than the former, and less divided.—Curled-leaved Cress.

All

All the varieties are proper to cultivate as small-sallad herbs, being of a warm or hot biting relish, are excellent to mix with larger sallading, such as lettuce, endive, &c. See SALLAD HERBS and SMALL SALLADING.

They are all propagated by seed sowed at many different times of the year, in order to continue a constant succession of young plants for use, for these herbs should always be cut for sallading when they are only a few days old; otherwise they will be too hot and strong tasted.

Therefore when a constant supply of those sallad herbs are required, they should be sowed every week all spring, summer, and autumn, and once every ten or twelve days in winter.

They should be sowed on warm borders early in spring; but as the warm weather advances, sow them in any open situation; but in summer should be sowed in somewhat shady borders, and in winter sowed in garden-frames, or under hand-glasses, and in severe weather are sowed in hot-beds.

And as to the method of sowing the seed, should be sowed very thick, either in shallow drills and covered a quarter of an inch deep, or all over the surface, and lightly raked in. See SMALL SALLADING.

LIMODORUM, Bastard Hellebore.

An herbaceous exotic, very ornamental in the stove, containing only one species.

Class and order, *Gynandria Diandria*.

Characters.] CALIX, a sheath from which the flower issues.—COROLLA, five oval oblong petals, the two upper ones connivent, and a monophyllous concave nectarium the length of the petals.—STAMINA, two, the filaments are in an oblong body, and rising upwards, these are topped with ovate twin antheræ.—PISTILLUM, a columnar germen the length of the corolla, and placed below the flower, the style is slender, and growing from the body of the filaments, is crowned with a funnel-shaped stigma.—PERICARPIUM, a columnar capsule, with three valves, and one cell opening at the angles, containing many scobiform seeds.

The specie is,

LIMODORUM *Tuberosum*.

Bastard Hellebore] The root is of the bulbous kind, from whence arises three or four leaves, each narrowed at the base, and ending

in a point, these are plaited; they are of a dark-green colour, and are nine or ten inches long, and one wide in the middle; the flower-stalk arises from the root to about eighteen inches high, this is smooth and of a brown purple colour; on the extremity of which the flowers are placed in a spike, about five or six in number, and inclining all one way; they are of a purplish-red colour, and are succeeded by a three-cornered columnar germen, which contain the seeds.

This plant should be always kept in the stove; it is increased by off-sets, which arise from the roots; these may be taken off in autumn or spring, and planted singly into small pots, and immediately plunged into the bark-bed.

M.

MIMULUS, Canada perfoliate Fox glove.

This genus comprehends one beautiful perennial species.

Class and order, *Didynamia Angiospermia*.

Characters.] CALIX, an oblong, prismatic, five-cornered, permanent cup, indented in five parts at top.—COROLLA, one ringent petal; the limb is bilabiated, the upper-lip is erect, bifid, rounded, and reflexed on the sides; the lower-lip is broad, and cut into three roundish segments, the middle one being the smallest; the palate is convex and bifid.—STAMINA, four filiforme filaments, two being shorter than the others, with bifid kidney-shaped antheræ.—PISTILLUM, a conical germen, the style slender, and an oval bifid, compressed stigma.—PERICARPIUM, an oval bilocular capsule, containing many small seeds.

The specie is,

MIMULUS *Ringens*.

Canada perfoliate Fox-glove.] The stalks of this plant are square-jointed, and rise upright about two feet; the leaves surround the stalk at each joint, they grow opposite, and are oblong, smooth, and pointed; the flowers are produced singly from the joints at the base of the leaves, and are large and of a beautiful blue colour; they appear in July, and are succeeded by capsules filled with seeds.

This species is propagated either by parting the roots or by seeds; the best time for either is autumn.

MORINA.

A hardy perennial plant, with upright deciduous

ciduous stalks, and prickly leaves, producing labiated flowers.

Class and order, *Diandria Monogynia*.

Characters.] CALIX, a double cup, each monophyllous, permanent, and tubular, cut at the top into two segments.—COROLLA, a bilabiated petal, with a very long tube, slender near the base, but wide and large at the top, and a little incurved, the limb is plane and obtuse, the upper-lip is small and semibifid; the lower-lip is cut into three obtuse segments, the middle one being the longest.—STAMINA, two setaceous filaments, shorter than the limb, with erect, heart-shaped antheræ.—PISTILLUM, a globose germen, placed under the receptacle of the flower, a slender style, and a capitated, peltated, inflexed stigma.—PERICARPIUM, none; the seed which is single and roundish stands in its own permanent cup, and is crowned with the empalement of the flower.

The specie is,

MORINA *Perfica*.

Oriental Morina.] The root of this plant is large, taper, oblong; strikes deep in the ground, and is furnished with many fibres; the radical leaves are very large and oblong, divided at their edges, armed with prickles, and of a bright green colour; the stalk is smooth, upright, and strong, rising to about a yard high, and furnished with lesser leaves of the same form as the radical; the flowers are produced at the sides and heads of the stalks in small heads; they appear in July, are of different colours; these are succeeded by the seeds.

The varieties of this specie are the white, —purple, —pale-red, —deep-red.

This plant is propagated by sowing the seeds when ripe; and as the roots are of the tap kind, the sowing should be where the plants are intended to flower; they will come up the succeeding summer, and the year following will exhibit their blossoms, which they will continue to do for several years following, if not disturbed.

N.

NOLANA.

An herbaceous trailing plant, much admired for the beauty of its pentandrious flowers.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, a monophyllous cup, turbinate, divided into five parts, and five

angles.—COROLLA, monopetalous, bell-shaped, plicated, and spreading, and double the size of the cup.—STAMINA, five erect awl-shaped filaments, shorter than the corolla, and topped with sagittate antheræ.—PISTILLUM, five roundish germens; the style is cylindric and strait, with a capitated stigma.—PERICARPIUM, none; but the seeds which are five, roundish, and of a succulent bark, are lodged in the inner base of a naked receptacle.

We know but of one species belonging to this genus.

NOLANA *Prostrata*.

The root is fibrous, from which issues a few trailing stalks furnished with deltoid leaves, about the length and breadth of an inch, of a dull-green colour; the flowers come out from the sides of the branches; they are of a fine blue colour, penciled with dark streaks, half way from the center to the limb, and the antheræ are of a light blue colour, which adds much to the beauty of the flower.

The Nolana is annual, it is raised by seeds sown on a hot-bed in the spring; the plants afterwards may by degrees be hardened to the open air, in which it will blow best part of the summer.

NYSSA, the Tupelo tree.

An ornamental tree, for the plantations, particularly where it is warm and moist, it is a native of North America.

Class and order, *Polygamia Dioecia*.

Characters.] Male.—CALIX, a peranthium, divided into five spreading segments.—COROLLA, none.—STAMINA, ten awl-shaped filaments, shorter than the cup, with didymous antheræ.—*Hermaphrodite.*—CALIX and COROLLA, the same as the male.—STAMINA, five subulate filaments, with single antheræ.—PISTILLUM, an oval germen, situated under the receptacle, a subulated incurved style, longer than the stamina, and an acute stigma.—PERICARPIUM, an oval drupe of one cell, containing an oval acute nut, marked with longitudinal furrows, angular and irregular.

The specie is,

NYSSA *Aquatica*.

The Virginian Tupelo-tree.] This tree rises with a regular trunk near twenty feet high, on the top of which several branches grow; the leaves are spear-shaped, soft, of a thickish consistence, and ending in acute points; they are very ornamental, of a fine light-green colour, grow alternately on pretty long foot.

foot-stalks, and retain their colour late in autumn.

Varieties.] Entire-leaved Tupelo,—serrated-leaved, or multiflorous Tupelo.

Their propagation is from seeds, which must be procured from America, but as the seeds come not up the first year they may be buried in pots of mould, and plunged where the ground is naturally moist, screening them from the frost in winter; the spring following let them be plunged in a hot-bed, which will soon vegetate the seeds, if they are good, and the plants will quickly appear, after which allow them a tolerable share of air, and harden them to it by degrees: the autumn following they should be sheltered in a greenhouse, or glass-frame during the winter; the third spring they should be separated and planted singly into small pots, and again plunged, &c. as before; shelter them again another winter, and in the spring following they may be planted where they are intended to remain, which should be in a well-sheltered and moist situation.

O.

OSYRIS, Poet's Cassia.

A plant of the shrubby kind; it grows naturally in the south of France, Italy, and Spain, upon rocky, sandy, or stony places.

Class and order, *Dioecia Triandria*.

Characters.] *Male.*—CALIX, a monophyllous turbinate cup, cut into three equal, oval, acute segments.—COROLLA, none.—STAMINA, three very short filaments, with small roundish antheræ.—*Female.* CALIX and COROLLA, as the male.—PISTILLUM, a top-shaped germen, situated below the cup, with a style the length of the stamina, and a stigma divided into three spreading parts.—PERICARPIUM, a globular umbilicated berry of one cell, containing the seed, which is a globular *officulum* filling the pericarpium.

The specie is,

OSYRIS *Alba*.

Poet's Cassia.] This species rises with a shrubby branching stalk to about two feet high; the leaves which are of a bright green are long, narrow, and pointed; the flowers appear in June, they are small and of a yellowish green colour, and succeeded by middle-sized roundish berries, which when ripe are of a bright red colour.

The propagation of this plant is by sowing

the berries on the rocky, sandy, or gravelly side of a hill, in the places where they are intended to remain, for as the beauty of this plant consists in its fruit, it will not so well succeed by raising them in the cultivated part of the garden, the berries always dropping off before they are come to maturity; the berries should be sown in autumn when ripe, and as they often remain in the ground two or three years before they vegetate, the places where they are sown should therefore be marked and all weeds kept clear from them.

P.

PANAX, Ginseng.

A genus of herbaceous umbelliferous plants, the root of which is much celebrated among the Chinese and Tartars, who affirm, it is a sovereign remedy for all kinds of disorders; its excellency consists in being restorative, and a great strengthener to the stomach.

Class and order, *Polygamia Dioecia*.

Characters.] *Hermaphrodite.*—CALIX, a simple, equal, and close umbel; the involucre is composed of several awl-shaped, small, permanent leaves; the proper cup is small and permanent.—COROLLA, the general flower is uniform; the florets have each five equal, oblong, recurved petals.—STAMINA, five very short filaments, with single antheræ.—PISTILLUM, a roundish germen placed below the flower, with two small upright styles, topped with simple antheræ.—PERICARPIUM, a heart-shaped umbilicated berry with two cells, each containing a single heart-shaped seed.—*Male.*—CALIX, a single and round umbel; the involucre is composed of several spear-shaped folioles, which are sessile, and the perianthium is turbinate, whole, and coloured.—COROLLA, is five oblong, blunt, narrow, reflexed petals, sitting on the cup.—STAMINA, five filiforme filaments, inserted in the cup, having simple antheræ.

Of this genus there are two species.

*PANAX *Quinquesolium*.

Or five-leaved Ginseng.] This plant has a fleshy taper root, brownish without, and yellow within, about a third of an inch in diameter on the upper-part, and of an agreeable bitter flavour; from this arises the stalk, to the height of about a foot, of a reddish colour, dividing at the top into three or four bunches, which support the leaves; these are quinate,

quinate, of a pale-green colour, the folioles of which are lanceolate, hairy, and ferrated; the flowers come out in umbels; they appear in June, and are succeeded by the seeds, which are ripe in August.

²PANAX *Trifolium*.

Three-leaved Ginseng.] Hath a small, taper, fleshy root, with trifoliate leaves, which are cut deeply on their edges; the flowers are produced in small bunches on foot-stalks; they are small and greenish.

POLYGALA, Milkwort.

This genus consists of herbaceous, perennial plants, the stalks rising from eight inches to eighteen, according to the different species, they are furnished with spear-shaped leaves and flowers growing in spikes.

Class and order, *Diadelphia Octandria*.

Characters.] CALIX, a small cup, composed of three oval, acute, permanent leaves, two of which are below the corolla, and the other above it.—COROLLA, papilionaceous; the wings are large, oval, plane, and placed beyond the other parts of the corolla; the vexillum is short, tubular, and a little reflexed, and bifid at top; the carina is concave, compressed, and ventricose towards the apex.—STAMINA, diadelphous filaments, with eight simple antheræ.—PISTILLUM, an oblong germen, a simple erect style, and a thickish bifid stigma.—PERICARPIUM, a turbinate, heart-shaped, compressed capsule, composed of two valves, having two cells, containing each a single oval seed.

The species are,

¹POLYGALA *Vulgaris*.

Common Milkwort.] This hath a root, which is long, slender, and white; the stalks are slender, herbaceous, growing on the ground, six or eight inches in length; the leaves are smooth, narrow, spear-shaped, pointed at the end, and of a bright-green colour, the flowers are produced from the ends of the stalks in crested spikes; they appear in June, and the seeds ripen in August.

Varieties.] Blue,—red,—white violet-coloured,—striped milk-wort,

²POLYGALA *Amara*.

Bitter Milkwort.] The radical leaves are large and oval, the stalks are herbaceous, erect, and six or eight inches high; the flowers are produced on the tops of the stalks in crested spikes of different colours; but chiefly blue; they appear in June, and the seeds

ripen in August. This plant is intolerably bitter to the taste.

³POLYGALA *Microphylla*.

Shrubby Portugal Milkwort.] The stalks are small, ligneous, of a green colour, growing about a foot high; the leaves which are placed alternately, are small, oval, awl-shaped, narrow, and sessile; the flowers are produced in short spikes on the tops of the stalks in May and June; they are large, and often of two or three colours; the seeds ripen in August.

⁴POLYGALA *Chamæbuxus*.

Dwarf Box Milkwort.] The stalks are slender, ligneous, and branching, about a foot high, the leaves are numerous, spear-shaped, smooth, and of a bright-green colour; the flowers come out from the sides of the stalks towards the upper-part; they are white without-side, with a mixture of purple and yellow within; they are very finely scented, and appear in May.

⁵POLYGALA *Senega*.

Senega Milkwort, or Rattle-snake-wort.] Hath a thick, fleshy, perennial root, which strikes deeply into the ground, from which arise three or four stalks, about half a yard high; these are herbaceous, upright, and slender; the leaves are spear-shaped, broad, and grow alternately; the flowers are produced at the ends of the stalks in spikes, they are small, of a white colour, appear in July, but seldom produce seeds in England.—The virtues of the root of this plant, when sufficiently known, will be very great in medicine; it is allowed to be a powerful cleanser of the blood, a fine diuretic, diaphoretic, and cathartic; it is used in hydropic cases, pleurifies, &c. but what makes it remarkable, is its being an infallible cure for the bite of a rattle-snake, if used in time, by reducing it to powder, rubbing the wound with it, and taking about thirty grains internally.

Propagation.

The first and second sorts are easily propagated by sowing the seeds when ripe, and keeping the ground clear of weeds; the third and fourth sorts are raised in the same manner, but require some protection from the frosts in winter: the fifth sort is also raised from seeds procured from America; they should be sown in light, warm, sandy ground, and in winter protected from the severity of the weather.

⁶POPULUS

⁶*POPULUS Canadensis*.—*Add*,

Canadian Poplar.] Rises with a strait trunk, regularly branching to a considerable height; the bark is whitish, the leaves are roundish, ending in an obtuse point, and the border waved, and of a light-green colour.

⁷*POPULUS Græca*.

Athenian Poplar.] Rises with a strait whitish stem, growing six or seven feet in a year, furnished with branches, which are garnished with large cordate leaves, of a beautiful green colour: this Poplar has but of late years been introduced into England, and by the rapidity of its growth, and the beauty of its leaves, bids fair to be the finest plant of all the species.

This species is best propagated by grafting on the Lombardy; but as it out grows the stock, it should therefore be grafted close to the ground.

PROTEA. The Silver-tree.

A genus of green-house plants of the perennial, evergreen, woody kind, growing to the height of eight or ten feet, and ornamented with beautiful silvery leaves, very much like fatten.

Class and order, *Tetandria Monogynia*.

Characters.] *CALIX*, a general imbricated perianthium, containing many florets, each having a monophyllous cup.—*COROLLA*, the general flower, which is uniform, consists of many monopetalous florets, cut at the limb into four parts, which are smooth and spreading.—*STAMINA*, four filaments inserted in the corolla, and incumbent antheræ.—*PISTILLUM*, a roundish germen, erect setaceous style, and obtuse stigma.—*PERICARPIMUM*, none; one seed to each floret lodged in its calix.

The species are,

¹*PROTEA Argentea*.

Cape Protea or Silver-tree.] Hath a strong upright, stalk, with a purplish bark; this divides into several erect branches, which are garnished with broad, lanceolate, silky-white, shining leaves, which continue all the year, rarely flowering in England.

²*PROTEA Conifera*.

Cone-bearing Protea.] Hath an upright stem, dividing into branches upwards, which are garnished with lanceolate, linear, entire leaves, of a shining silvery colour, the whole plant making a fine appearance.

Both sorts are propagated by seeds pro-

cured from the Cape of Good Hope; these should be sown on a moderate hot-bed in the spring, and when the plants are up, should be housed in any airy glass-case, or the coolest part of the green-house; but by no means put them in the stove, which is certain death to them, as they cannot bear fire heat, requiring only to be sheltered from frost, &c.

S.

SARRACENIA, Side-saddle flower.

A genus much admired for the singularity of their leaves and flowers; they are perennial and herbaceous, the leaves are numerous, of a peculiar construction, and the flowers are single and polyandrious: it admits of two species.

Class and order, *Polyandria Monogynia*.

Characters.] *CALIX*, a double perianthium, the lower are compounded of three small, oval, deciduous leaves, and the upper one of five large coloured leaves, which also fade away.—*COROLLA*, five oval inflexed petals covering the stamina with oval oblong claws.—*STAMINA*, a number of small filaments, topped with simple antheræ.—*PISTILLUM*, a roundish germen, the style very short and cylindric, topped with a cylpeated, peltated, quinquangular stigma, covering the stamina.—*PERICARPIMUM*, a five-celled roundish germen, containing many roundish-pointed small seeds.

The species are,

¹*SARRACENIA Purpurea*.

Purple Sarracenia.] Hath a fibrous root, striking deep in the ground; the leaves are pitcher-shaped, of a firm substance, arising from a small base, and widening by degrees to the neck in an upright position, so as to contain a quantity of water; from the root arises the flower stem; it grows to the height of half a yard, and is round, naked and upright; the flowers decorate the top of the stalks, and are single, large, of a fine purple colour, and hang drooping; they appear in June, and sometimes the seeds ripen in autumn.

²*SARRACENIA Flava*.

Yellow Sarracenia.] Hath a root like the former; the leaves are numerous, hollow, standing on a slender base, wide at the top, and grow to the height of a yard; the stalks are naked, on the tops of which the flowers are produced, which grow singly, and of a yellow colour, and come out in June or July;

a va-

a variety of this species hath green flowers. These plants are natives of moist boggy places in North America; their situation in England should therefore be similar; but severe frosts should be guarded against for their protection; the readiest way of procuring, (if not in England), is to have them from North America, as there is at present no mode of propagation here, yet discovered.

SOPHORA.

Consists of a genus of perennial plants, whose leaves are winged, and the flowers produced in spikes.

Class and order, *Decandria Monogynia*.

Characters.] CALIX, a short monophyllous, bell-shaped cup, divided at the top into five oblique blunt segments.—COROLLA, papilionaceous and quinpetalous; the vexillum is oblong, broader at top, and reflexed on the sides; the wings are two, oblong and appendiculated at their base; the carina is composed of two petals like the wings, with their lower edges joined together.—STAMINA, ten distinct awl-shaped filaments concealed in the carina, with very small assurgent antheræ.—PISTILLUM, an oblong taper germen, the style the size and situation of the stamina, and an obtuse stigma.—PERICARPIUM, a long, slender, unilocular pod, containing many roundish seeds.

There are two species of this genus, which are hardy.

¹SOPHORA *Alopecuroides*.

Oriental Sophora.] Hath a creeping root, from which the stalks arise; they are upright, and three or four feet in height, the leaves are winged, composed of many small, oblong, hairy folioles, ending with an odd one; the flowers come out in spikes from the sides and ends of the stalks, and are of a pale blue colour, appearing in July.

²SOPHORA *Tinctoria*.

Virginian Sophora.] Hath a perennial root, from whence arise many weak procumbent stalks; the leaves are composed of three roundish smooth folioles, which join at the base, and grow on very short foot-stalks; the flowers are produced in short spikes in July; they are of a yellow colour, and sometimes succeeded by seeds, which ripen in autumn. To these may be added two other species, which are perennial, of the shrub kind, but being tender, require a stove.

³SOPHORA *Mirophylla*.

Small-leaved Otabeite Sophora.] This hath

been lately introduced into this kingdom; the whole plant is very elegant, the leaves are winged, the folioles, which are numerous, are roundish, about a quarter of an inch long, of a dark green colour.

⁴SOPHORA *Tomentosa*.

Silvery Ceylon Sophora.] Hath a downy stalk, rising six or seven feet high; the leaves are winged, consisting of five or six pair of folioles, which are roundish and woolly; the flowers grow in spikes, and are of a yellow colour; these are succeeded by woolly taper pods, which contain the seeds.

The first and second sorts are propagated by parting their roots in autumn or spring; they may also be raised by sowing their seeds.—The third and fourth are propagated by sowing their seeds on a hot-bed; the plants from thence arising, when fit, should be potted and plunged into the bark-bed in the stove, where they should be constantly kept.

STAPELIA, Swallow-wort.

Consists of two species of succulent, perennial plants, which are destitute of leaves, producing from the sides of the stalks; variegated pentandrious flowers of a singular appearance.

Class and order, *Pentandria Digynia*.

Characters.] CALIX, monophyllous, small, acute, divided into five parts, and persistent.—COROLLA, monopetalous, large, flat, divided half way into five parts, and containing a starry, five-pointed nectarium, with linear segments, whose lacerated points surround the parts of generation.—STAMINA, five plain, broad, erect filaments, with linear antheræ joined to the sides of the filaments.—PISTILLUM, two oval plane germens, without a style, each having a blunt stigma.—PERICARPIUM, two oblong, subulate pods, with single cells and valves, containing many imbricated compressed seeds, crowned with a pappose down.

The species are,

¹STAPELIA *Maculata*.

Spotted Stapelia or Fritillaria Crassa Minor.] Hath many succulent spreading branches, with several protuberancies on their sides rising about six inches; from the sides of the branches are produced the flowers, which are single, seldom shewing more than two at a time, which are continued in succession, each consists of a stellated petal, which spreads open, green on the outside, but yellow within, and spotted with deep purple;

purple; the centre is occupied by a coloured nectarium, which includes the parts of generation, when the flower is decayed; the germen are succeeded by two taper pods, which join at their base, and contain many seeds crowned with feathery down.

²*STAPELIA Hirsuta.*

Hairy Stapelia or Frittillaria Crassa Major.] Hath upright succulent branches, which are angulated and indentured on the edges, and of a greenish-purple colour; from the sides of the branches the flowers are produced; they are large, stellated, hairy, and variegated with purple stripes, which run across the petal: both the species shew their flowers in the summer months, which are of so very foetid a scent as to induce the flesh-flies to lay their eggs thereon. These plants should be kept always in the stove on the flue or shelves, where they will blow every summer, observing to let them have but little water in winter. They are easily propagated by the branches being slipped off, and laying them by for a few days in the sun to heal the wound, after which they may be put in pots with poor earth, not over moist, and plunged in the tan, where they will readily take root in any of the summer months.

T.

TELEPHIUM, Orpine.

Consists of a perennial plant, whose stalks are procumbent; the leaves small, and oval, and the flowers produced in spikes.

Class and order, *Pentandria Trigynia.*

Characters.] CALIX, five oblong, blunt, concave, carinated, permanent leaves.—COROLLA, five oblong, obtuse, erect petals, narrowed at the base.—STAMINA, five subulate filaments, with incumbent antheræ.—PISTILLUM, a three-sided acute germen without a style, with three acute patent stigmas.—PERICARPIUM, a short three-sided capsules, formed of three valves and one cell, containing many roundish seeds.

The specie is,

TELEPHIUM Imperati.

Orpine of Imperatus, or Live-long.] Hath a thick, hard, fibrous root, of a yellowish colour, the stalks which lie on the ground are numerous, round, slender, green, eight or ten inches long; the leaves are small, oval, stiff, smooth, of a greyish colour, and grow alternately; the flowers are produced in short,

thick, reflexed spikes, and grow at the ends of the branches; their colour is white, appear in June or July, and the seeds are ripe in autumn. This plant is propagated by sowing the seeds in autumn on a light and dry soil, where they are to remain; the succeeding spring the plants will be up, and the next year will bloom and ripen their seeds.

THEA. The Tea-tree.

An ever-green, woody, Chinese plant, the dried prepared leaves of which are universally made use of; the flowers are polyandrious and rosaceous.

Class and order, *Polyandria Monogynia.*

Characters.] CALIX, a small flat, perianthium, divided into six parts, the folioles of which are roundish, blunt, and persistent.—COROLLA, six roundish, large, concave petals, which are equal.—STAMINA, many slender filaments, shorter than the corolla, with simple antheræ.—PISTILLUM, a three-cornered globose germen with an awl-shaped style, crowned with a tripple stigma.—PERICARPIUM, a trilocular capsule, joining in three round bodies, and opening at the top.—SEMINA, the seeds are single, round and angulated at their backs.

There are supposed to be two distinct species, the leaves of which are imported in great quantities from China, and go by the denomination of green and bohea tea; but as it is not yet settled by botanists, whether the two sorts are from one or distinct plants, we shall confine ourselves to the sort growing here in England.

THEA.

The Tea-tree.] Hath a fibrous root, from which rises a stem covered with an ash-coloured bark; the leaves are placed alternately on the branches; they are oval, obtusely pointed, sawed at their edges, are about two inches wide and four long, of a dark green colour; the flowers which come out from the sides of the branches are rosaceous, and of a white colour; these are succeeded by a capsule with three cells, each containing a single seed. The tea-tree is not so tender as many imagine, for it will not succeed well in the stove; there are some few planted in the natural ground, where they seem to thrive best; the situation should be in a well sheltered part of the garden, where it is not too moist, and in winter they should be protected from severe weather; here they will thrive much better

better than keeping them in pots in the house, and will shew plenty of blossoms; they are propagated by layers.

V.

VACCINIUM, Whortle-berry, Bilberry, or Cranberry.

Comprehend a genus of dwarf shrubby plants, producing eatable fruit.

Class and order, *Ostendria Monogynia*.

Characters.] CALIX, a very small perianthium, situated above the germen.—COROLLA, a campanulated petal, divided at the brim into four revolved segments.—STAMINA, eight simple filaments, with two horned antheræ, opening at the point, and furnished with two spreading aristæ on the outside.—PISTILLUM, a germen situated below the cup, a single style longer than the stamina, and an obtuse stigma.—PERICARPIUM, a globular umbilicated berry, with four cells, containing a few small seeds.

Of this genus are the following species.

¹VACCINIUM *Myrtillis*.

Bilberry or Black-whorts.] Hath an angular, branching, shrubby stalks, growing to the height of about two feet; the leaves are oval, oblong, a little serrated, smooth, of a dark-green colour, and fall off in winter; the flowers come out singly from the ends and sides of the branches, on foot-stalks of a greenish-white colour, appearing in April and May, which are succeeded by large eatable berries.

²VACCINIUM *Uliginosum*.

Great Bilberry.] Hath a woody branching stalk, which rises to about three feet; the leaves are thin, veined, oval, entire, and underneath whitish; the flowers grow singly on their separate foot-stalks, are of a whitish-purple colour; they appear in April and May, and are succeeded by large berries which ripen in July.

³VACCINIUM *Album*.

White Bilberry.] Hath a stalk which rises to

about half a yard in height, is woody and branching; the leaves are entire, oval, and downy underneath, the flowers are produced from the ends and sides of the branches in small clusters; they appear in May, and are succeeded by berries, when ripe they are of a white colour.

⁴VACCINIUM *Vites Idæa*.

Red Whortle-berry.] Hath very slender branching stalks, growing about six inches high, the leaves are ever-green, of a firm consistence, oval, and smooth, and maculated on their under-side; the flowers grow in clusters from the ends of the branches; they are of a reddish colour, and appear in May, and are succeeded by red juicy berries, which when ripe are much esteemed for tarts.

⁵VACCINIUM *Oxycoccus*.

Cranberry.] Hath slender procumbent stalks, the leaves are small, oval, entire, and reflexed on their edges; the flowers grow on long slender foot-stalks at the tops of the branches, are of a red colour; appear in May and June, and are succeeded by berries, well known for tarts.

⁶VACCINIUM *Hispidulum*.

Marsh Virginian Whortle-berry.] Hath trailing stalks, which are slender, rough, and imbricated; the leaves which turn backward are oval and entire; the flowers are produced from the tops of the branches on slender foot-stalks; they appear in May, and are succeeded by very large red berries.

The four first sorts grow naturally in cold, light, sandy woods, heaths, &c. To propagate them the roots should be taken up from the places where they grow spontaneously, reserving a quantity of mould to them, and planting them in a similar soil and situation; in such places they will thrive and encrease. The two last species require a boggy undisturbed marshy soil, to which the plants must be removed from where they naturally grow. The berries of most of the sorts are noted for making excellent tarts, &c.

about half a yard in height is woody and
leaves; the leaves are entire, oval and
green underneath, the flowers are produced
from the ends and sides of the branches in
small clusters; they appear in June, and are
fertilized by bees, which are the only
insects that visit them.

Asplenium adnigrum L.
This is a small plant, growing about six inches
high; the leaves are oval, and of a fine
green color, and are produced from the
ends of the branches; the flowers are in
small clusters, and are fertilized by bees.
It is a very common plant, and is found
in many places.

Asplenium adnigrum L.
This is a small plant, growing about six inches
high; the leaves are oval, and of a fine
green color, and are produced from the
ends of the branches; the flowers are in
small clusters, and are fertilized by bees.
It is a very common plant, and is found
in many places.
